DBMS_DATAPUMP

The DBMS_DATAPUMP package is used to move all, or part of, a database between databases, including both data and metadata.

> **See Also:**
>
> *Oracle Database Utilities* for more information on the concepts behind the DBMS_DATAPUMP API, how it works, and how it is implemented in the Data Pump Export and Import utilities

This chapter contains the following topics:

- Overview
- Security Model
- Constants
- Data Structures
- Summary of DBMS_DATAPUMP Subprograms

54.1 DBMS_DATAPUMP Overview

DBMS_DATAPUMP provides the following support and functionality.

- The source and target databases can have different hardware, operating systems, character sets, time zones, and versions.
- All object types and datatypes existing in Oracle Database 11*g* and higher are supported.
- Data and metadata can be transferred between databases without using any intermediary files.
- A subset of a database can be moved based upon object type and names of objects.
- Schema names, data file names, tablespace names, and data can be transformed at import time.
- Previously aborted export and import jobs can be restarted without duplicating or omitting any data or metadata from the original job.
- The resources applied to an export or import job can be modified.
- Data in an Oracle proprietary format can be unloaded and loaded.

54.2 DBMS_DATAPUMP Security Model

Security for the DBMS_DATAPUMP package is implemented through roles.

The DATAPUMP_EXP_FULL_DATABASE and DATAPUMP_IMP_FULL_DATABASE roles allow privileged users to take full advantage of the API. The Data Pump API will use these roles to determine whether privileged application roles should be assigned to the processes comprising the job.

- DATAPUMP_EXP_FULL_DATABASE

  The DATAPUMP_EXP_FULL_DATABASE role affects only Export operations. It allows users running these operations to do the following:

  – Perform the operation outside of the scope of their schema
  – Monitor jobs that were initiated by another user
  – Export objects (for example, TABLESPACE definitions) that unprivileged users cannot reference

  Although the SYS schema does not have the DATAPUMP_EXP_FULL_DATABASE role assigned to it, all security checks performed by Data Pump that require the DATAPUMP_EXP_FULL_DATABASE role will also grant access to the SYS schema.

- DATAPUMP_IMP_FULL_DATABASE

  The DATAPUMP_IMP_FULL_DATABASE role affects only Import and SQL_FILE operations. It allows users running these operations to do the following:

  – Perform the operation outside of the scope of their schema
  – Monitor jobs that were initiated by another user
  – Import objects (for example, DIRECTORY definitions) that unprivileged users cannot create

  Although the SYS schema does not have the DATAPUMP_IMP_FULL_DATABASE role assigned to it, all security checks performed by Data Pump that require the DATAPUMP_IMP_FULL_DATABASE role will also grant access to the SYS schema.

54.3 DBMS_DATAPUMP Constants

There are several public constants defined for use with the DBMS_DATAPUMP.GET_STATUS procedure. All such constants are defined as part of the DBMS_DATAPUMP package. Any references to these constants must be prefixed by DBMS_DATAPUMP. and followed by the symbols in the following lists:

Mask Bit Definitions

The following mask bit definitions are used for controlling the return of data through the DBMS_DATAPUMP.GET_STATUS procedure.

- `KU$_STATUS_WIP CONSTANT BINARY_INTEGER := 1;`
- `KU$_STATUS_JOB_DESC CONSTANT BINARY_INTEGER := 2;`
- `KU$_STATUS_JOB_STATUS CONSTANT BINARY_INTEGER := 4;`
- `KU$_STATUS_JOB_ERROR CONSTANT BINARY_INTEGER := 8;`

Dump File Type Definitions

The following definitions are used for identifying types of dump files returned through the DBMS_DATAPUMP.GET_STATUS procedure.

- KU$_DUMPFILE_TYPE_DISK CONSTANT BINARY_INTEGER := 0;
- KU$_DUMPFILE_TYPE_TEMPLATE CONSTANT BINARY_INTEGER := 3;

54.4 DBMS_DATAPUMP Data Structures

The DBMS_DATAPUMP package defines OBJECT types. The types described in this section are defined in the SYS schema for use by the GET_STATUS function. *The way in which these types are defined and used may be different than what you are accustomed to. Be sure to read this section carefully.*

The collection of types defined for use with the GET_STATUS procedure are version-specific and include version information in the names of the types. Once introduced, these types will always be provided and supported in future versions of Oracle Database and will not change. However, in future releases of Oracle Database, new versions of these types might be created that provide new or different information. The new versions of these types will have different version information embedded in the type names.

For example, in Oracle Database 12*c*, Release 1 (12.1), there is a sys.ku$_Status1210 type, and in the next Oracle Database release, there could be a sys.ku$_Status1310 type defined. Both types could be used with the GET_STATUS procedure.

Public synonyms have been defined for each of the types used with the GET_STATUS procedure. This makes it easier to use the types and means that you do not have to be concerned with changes to the actual type names or schemas where they reside. Oracle recommends that you use these synonyms whenever possible.

For each of the types, there is a version-specific synonym and a generic synonym. For example, the version-specific synonym ku$_Status1210 is defined for the sys.ku$_Status1210 type.

The generic synonym always describes the latest version of that type. For example, in Oracle Database 12*c*, Release 1 (12.1), the generic synonym ku$_Status is defined as ku$_Status1210. In a future release, there might be a ku$_Status1310 synonym for sys.ku$Status1310. Because the ku$_Status generic synonym always points to the latest definition, it would then point to ku$_Status1310 rather than to ku$_Status1210.

The choice of whether to use version-specific synonyms or generic synonyms makes a significant difference in how you work. Using version-specific names protects your code from changes in future releases of Oracle Database because those types will continue to exist and be supported. However, access to new information will require code changes to use new synonym names for each of the types. Using the generic names implies that you always want the latest definition of the types and are prepared to deal with changes in different releases of Oracle Database.

When the version of Oracle Database that you are using changes, any C code that accesses types through generic synonym names will need to be recompiled.

> **Note:**
>
> Languages other than PL/SQL must ensure that their type definitions are properly aligned with the version-specific definitions.

> **See Also:**
>
> GET_STATUS Procedure for additional information about how types are used

Data Structures — Object Types

The DBMS_DATAPUMP package defines the following kinds of OBJECT types:

- Worker Status Types
- Log Entry and Error Types
- Job Status Types
- Job Description Types
- Status Types

Worker Status Types

The worker status types describe what each worker process in a job is doing. The schema, object name, and object type of an object being processed will be provided. For workers processing user data, the partition name for a partitioned table (if any), the number of bytes processed in the partition, and the number of rows processed in the partition are also returned. Workers processing metadata provide status on the last object that was processed. No status for idle threads is returned.

The percent_done refers to the amount completed for the current data item being processed. It is not updated for metadata objects.

The worker status types are defined as follows:

```
CREATE TYPE sys.ku$_WorkerStatus1010 AS OBJECT
       (
               worker_number     NUMBER,       -- Worker process identifier
               process_name      VARCHAR2(30), -- Worker process name
               state             VARCHAR2(30), -- Worker process state
               schema            VARCHAR2(30), -- Schema name
               name              VARCHAR2(4000),-- Object name
               object_type       VARCHAR2(200),-- Object type
               partition         VARCHAR2(30), -- Partition name
               completed_objects NUMBER,       -- Completed number of objects
               total_objects     NUMBER,       -- Total number of objects
               completed_rows    NUMBER,       -- Number of rows completed
               completed_bytes   NUMBER,       -- Number of bytes completed
               percent_done      NUMBER        -- Percent done current object
       )

CREATE OR REPLACE PUBLIC SYNONYM ku$_WorkerStatus1010
  FOR sys.ku$_WorkerStatus1010;
```

```
CREATE TYPE sys.ku$_WorkerStatus1020 AS OBJECT
        (
                worker_number     NUMBER,       -- Worker process identifier
                process_name      VARCHAR2(30), -- Worker process name
                state             VARCHAR2(30), -- Worker process state
                schema            VARCHAR2(30), -- Schema name
                name              VARCHAR2(4000),-- Object name
                object_type       VARCHAR2(200),-- Object type
                partition         VARCHAR2(30), -- Partition name
                completed_objects NUMBER,       -- Completed number of objects
                total_objects     NUMBER,       -- Total number of objects
                completed_rows    NUMBER,       -- Number of rows completed
                completed_bytes   NUMBER,       -- Number of bytes completed
                percent_done      NUMBER,       -- Percent done current object
                degree            NUMBER        -- Degree of parallelism
        )

CREATE OR REPLACE PUBLIC SYNONYM ku$_WorkerStatusList1020
  FOR sys.ku$_WorkerStatusList1020;
CREATE OR REPLACE PUBLIC SYNONYM ku$_WorkerStatusList1120
  FOR sys.ku$_WorkerStatusList1120;
CREATE OR REPLACE PUBLIC SYNONYM ku$_WorkerStatusList1210
  FOR sys.ku$_WorkerStatusList1210;
CREATE OR REPLACE PUBLIC SYNONYM ku$_WorkerStatusList1220
  FOR sys.ku$_WorkerStatusList1220;

CREATE OR REPLACE PUBLIC SYNONYM ku$_WorkerStatusList
  FOR ku$_WorkerStatusList1220;
```

Log Entry and Error Types

These types provide informational and error text to attached clients and the log stream. The `ku$LogLine.errorNumber` type is set to `NULL` for informational messages but is specified for error messages. Each log entry may contain several lines of text messages.

The log entry and error types are defined as follows:

```
CREATE TYPE sys.ku$_LogLine1010 AS OBJECT (
               logLineNumber   NUMBER,
               errorNumber     NUMBER,
               LogText         VARCHAR2(2000))

CREATE OR REPLACE PUBLIC SYNONYM ku$_LogLine1010 FOR sys.ku$_LogLine1010;
CREATE OR REPLACE PUBLIC SYNONYM ku$_LogLine1020 FOR sys.ku$_LogLine1010;
CREATE OR REPLACE PUBLIC SYNONYM ku$_LogLine FOR ku$_LogLine1010;
CREATE TYPE sys.ku$_LogEntry1010 AS TABLE OF sys.ku$_LogLine1010

CREATE OR REPLACE PUBLIC SYNONYM ku$_LogEntry1010 FOR sys.ku$_LogEntry1010;
CREATE OR REPLACE PUBLIC SYNONYM ku$_LogEntry1020 FOR sys.ku$_LogEntry1010;
CREATE OR REPLACE PUBLIC SYNONYM ku$_LogEntry FOR ku$_LogEntry1010;
```

Job Status Types

The job status type returns status about a job. Usually, the status concerns a running job, but it could also be about a stopped job when a client attaches. It is typically requested at attach time, when the client explicitly requests status from interactive mode and every *N* seconds when the client has requested status periodically.

The job status types are defined as follows (`percent_done` applies to data only):

```
CREATE TYPE sys.ku$_JobStatus1010 IS OBJECT
       (
               job_name        VARCHAR2(30),           -- Name of the job
               operation       VARCHAR2(30),           -- Current operation
               job_mode        VARCHAR2(30),           -- Current mode
               bytes_processed NUMBER,                 -- Bytes so far
               total_bytes     NUMBER,                 -- Total bytes for job
               percent_done    NUMBER,                 -- Percent done
               degree          NUMBER,                 -- Of job parallelism
               error_count     NUMBER,                 -- #errors so far
               state           VARCHAR2(30),           -- Current job state
               phase           NUMBER,                 -- Job phase
               restart_count   NUMBER,                 -- #Job restarts
               worker_status_list ku$_WorkerStatusList1010, -- For (non-idle)
                                                       -- job worker processes
               files           ku$_DumpFileSet1010     -- Dump file info
       )

CREATE OR REPLACE PUBLIC SYNONYM ku$_JobStatus1010 FOR sys.ku$_JobStatus1010;

CREATE TYPE sys.ku$_JobStatus1020 IS OBJECT
       (
               job_name        VARCHAR2(30),           -- Name of the job
               operation       VARCHAR2(30),           -- Current operation

Job Description Types

The job description type holds all the environmental information about the job such as parameter settings and dump file set members. There are a couple of subordinate types required as well.

The job description types are defined as follows:

```
CREATE TYPE sys.ku$_JobDesc1010 IS OBJECT
        (
                job_name        VARCHAR2(30),           -- The job name
                guid            RAW(16),                -- The job GUID
                operation       VARCHAR2(30),           -- Current operation
                job_mode        VARCHAR2(30),           -- Current mode
                remote_link     VARCHAR2(4000),         -- DB link, if any
                owner           VARCHAR2(30),           -- Job owner
                instance        VARCHAR2(16),           -- The instance name
                db_version      VARCHAR2(30),           -- Version of objects
                creator_privs   VARCHAR2(30),           -- Privs of job
                start_time      DATE,                   -- This job start time
                max_degree      NUMBER,                 -- Max. parallelism
                log_file        VARCHAR2(4000),         -- Log file name
                sql_file        VARCHAR2(4000),         -- SQL file name
                params          ku$_ParamValues1010     -- Parameter list
        )

CREATE OR REPLACE PUBLIC SYNONYM ku$_JobDesc1010 FOR sys.ku$_JobDesc1010;

CREATE TYPE sys.ku$_JobDesc1020 IS OBJECT

Status Types

The status type is an aggregate of some the previous types defined and is the return value for the `GET_STATUS` call. The mask attribute indicates which types of information are being returned to the caller. It is created by a client's shadow process from information it retrieves off the status queue or directly from the master table.

For errors, the `ku$_LogEntry` that is returned has already had its log lines ordered for proper output. That is, the original `ku$_LogEntry` objects have been ordered from outermost context to innermost.

The status types are defined as follows:

```
CREATE TYPE sys.ku$_Status1010 IS OBJECT
        (
                mask            NUMBER,           -- Status types present
                wip             ku$_LogEntry1010, -- Work in progress
                job_description ku$_JobDesc1010,  -- Complete job description
                job_status      ku$_JobStatus1010,-- Detailed job status
                error           ku$_LogEntry1010  -- Multi-level context errors
        )

CREATE OR REPLACE PUBLIC SYNONYM ku$_Status1010 FOR sys.ku$_Status1010;

CREATE TYPE sys.ku$_Status1020 IS OBJECT
        (
                mask            NUMBER,           -- Status types present
                wip             ku$_LogEntry1010, -- Work in progress
                job_description ku$_JobDesc1020,  -- Complete job description
```

```
                job_status      ku$_JobStatus1020,-- Detailed job status

```

54.5 Summary of DBMS_DATAPUMP Subprograms

This table lists the DBMS_DATAPUMP subprograms in alphabetical order and briefly describes them.

Table 54-1 DBMS_DATAPUMP Package Subprograms

Subprogram	Description
ADD_FILE Procedure	Adds dump files to the dump file set for an Export, Import, or SQL_FILE operation. In addition to dump files, other types of files can also be added by using the FILETYPE parameter provided with this procedure.
ATTACH Function	Used to gain access to a Data Pump job that is in the Defining, Executing, Idling, or Stopped state
DATA_FILTER Procedures	Specifies restrictions on the rows that are to be retrieved

Table 54-1 (Cont.) DBMS_DATAPUMP Package Subprograms

Subprogram	Description
DATA_REMAP Procedure	Specifies transformations to be applied to column data as it is exported from, or imported into, a database.
DETACH Procedure	Specifies that the user has no further interest in using the handle
GET_DUMPFILE_INFO Procedure	Retrieves information about a specified dump file
GET_STATUS Procedure	Monitors the status of a job or waits for the completion of a job or for more details on API errors
LOG_ENTRY Procedure	Inserts a message into the log file
METADATA_FILTER Procedure	Provides filters that allow you to restrict the items that are included in a job
METADATA_REMAP Procedure	Specifies a remapping to be applied to objects as they are processed in the specified job
METADATA_TRANSFORM Procedure	Specifies transformations to be applied to objects as they are processed in the specified job
OPEN Function	Declares a new job using the Data Pump API, the handle returned being used as a parameter for calls to all other procedures (but not to the ATTACH function)
SET_PARALLEL Procedure	Adjusts the degree of parallelism within a job
SET_PARAMETER Procedures	Specifies job-processing options
START_JOB Procedure	Begins or resumes execution of a job
STOP_JOB Procedure	Terminates a job, but optionally, preserves the state of the job
WAIT_FOR_JOB Procedure	Runs a job until it either completes normally or stops for some other reason

54.5.1 ADD_FILE Procedure

This procedure adds files to the dump file set for an Export, Import, or SQL_FILE operation, or specifies the log file or the output file for a SQL_FILE operation.

Syntax

```
DBMS_DATAPUMP.ADD_FILE (
   handle     IN NUMBER,
   filename   IN VARCHAR2,
   directory  IN VARCHAR2,
   filesize   IN VARCHAR2 DEFAULT NULL,
   filetype   IN NUMBER DEFAULT DBMS_DATAPUMP.KU$_FILE_TYPE_DUMP_FILE,
   reusefile  IN NUMBER DEFAULT NULL);
```

Parameters

Table 54-2 ADD_FILE Procedure Parameters

Parameter	Description
handle	The handle of a job. The current session must have previously attached to the handle through a call to either the OPEN or ATTACH function.
filename	The name of the file that is being added. The filename parameter must be a simple filename without any directory path information. For dump files, the filename can include a substitution variable. For a description of available substitution variables, see the following table. The file can be written to or read from either the local file system or the Oracle Object Store. If you are interfacing with the local file system, the filename parameter must contain a filename without directory path information. If you are interfacing with the Oracle Object Store, the filename parameter must contain a valid URI to the location of a bucket within your compartment in the Oracle Object Store. You must also specify a valid CREDENTAL in the directory parameter to access the bucket and the DBMS_DATAPUMP.KU$_FILE_TYPE_URIDUMP_FILE file type in the filetype parameter. For examples, see *Using the Oracle Data Pump API* in *Oracle Database Utilities Guide*.
directory	If you are interfacing with the local file system, then the directory parameter specifies the name of a directory object within the database that is used to locate the filename. If you are interfacing with the Oracle Object Store, then the directory parameter must specify a valid CREDENTIAL to access the bucket where filename resides. Ensure that you specify a valid directory parameter.
filesize	The size of the dump file that is being added. It can be specified as: • the number of bytes • number of kilobytes (if followed by K) • the number of megabytes (if followed by M) • the number of gigabytes (if followed by G) • the number of terabytes (if followed by T) An Export operation will write no more than the specified number of bytes to the file. When the file is full, it will be closed. If there is insufficient space on the device to write the specified number of bytes, then the Export operation will fail, but it can be restarted. If not specified, filesize will default to an unlimited size. For Import and SQL_FILE operations, filesize is ignored. The minimum value for filesize is ten times the default Data Pump block size, which is 4 kilobytes. A filesize can only be specified for dump files.
filetype	The type of the file that you want to add. The supported values are as follows: • DBMS_DATAPUMP.KU$_FILE_TYPE_DUMP_FILE—dump file for a job • DBMS_DATAPUMP.KU$_FILE_TYPE_LOG_FILE—log file for a job • DBMS_DATAPUMP.KU$_FILE_TYPE_SQL_FILE—output for SQL_FILE job • DBMS_DATAPUMP.KU$_FILE_TYPE_URIDUMP_FILE—Specifies a filename in the Oracle Object Store. For more information, see the filename and directory parameters described above.

Table 54-2 (Cont.) ADD_FILE Procedure Parameters

Parameter	Description
reusefile	If the value is 0, then a preexisting file will cause an error. If 1, then a preexisting file will be overwritten. If NULL, then the default action for the file type will be applied (that is, dump files will not be overwritten). This parameter should only be non-NULL for dump files. The reusefile parameter is restricted to export jobs.

Substitution Variables

Table 54-3 Substitution Variables Available for the Filename Parameter on DBMS_DATAPUMP.ADD_FILE

Substitution Variable	Description
%U	The %U is expanded in the resulting file names into a two-character, fixed-width, incrementing integer starting at 01. For example, the dump filename of export%U would cause export01, export02, export03, and so on, to be created depending on how many files are needed to perform the export. For filenames containing the % character, the % must be represented as %% to avoid ambiguity.
%d, %D	Specifies the current day of the month from the Gregorian calendar in format DD. Note: This substitution variable cannot be used in an import file name.
%m, %M	Specifies the month in the Gregorian calendar in format MM. Note: This substitution variable cannot be used in an import file name.
%t, %T	Specifies the year, month, and day in the Gregorian calendar in this format: YYYYMMDD. Note: This substitution variable cannot be used in an import file name.
%l, %L	Specifies a system-generated unique file name. The file names can contain a substitution variable (%L), which implies that multiple files may be generated. The substitution variable is expanded in the resulting file names into a 2-digit, fixed-width, incrementing integer starting at 01 and ending at 99 which is the same as (%U). In addition, the substitution variable is expanded in the resulting file names into a 3-digit to 10-digit, variable-width, incrementing integers starting at 100 and ending at 2147483646. The width field is determined by the number of digits in the integer. For example if the current integer was 1, exp%Uaa%U.dmp would resolve to exp01aa01.dmp exp02aa02.dmp and so forth up until 99. Then, the next file name would have 3 digits substituted: exp100aa100.dmp exp101aa101.dmp and so forth up until 999 where the next file would have 4 digits substituted. The substitution will continue up to the largest number substitution allowed, which is 2147483646.
%y, %Y	Specifies the year in this format: YYYY. Note: This substitution variable cannot be used in an import file name.

Exceptions

- INVALID_HANDLE. The specified handle is not attached to an Oracle Data Pump job.
- INVALID_ARGVAL. An invalid value was supplied for an input parameter.
- INVALID_STATE. The job is completing, or the job is past the defining state for an import or SQL_FILE job, or is past the defining state for LOG and SQL files.
- INVALID_OPERATION. A dump file was specified for a Network Import or ESTIMATE_ONLY export operation.
- SUCCESS_WITH_INFO. The procedure succeeded, but further information is available through the GET_STATUS procedure.
- NO_SUCH_JOB. The specified job does not exist.

Usage Notes

- This procedure adds files to an Oracle Data Pump job. You can add the following types of files to a job:
  - Log files—To record the messages associated with an operation. The Log file overwrites the previously existing files.
  - SQL files—To record the output of a SQL_FILE operation. The SQL file overwrites the previously existing files.
  - Dump files—To contain the data that is being moved. The Dump files do not overwrite the existing files. However, an error is generated.
- Import and SQL_FILE operations require that that you specify all dump files during the definition phase of the job. For Export operations, dump files can be added at any time. For example, if the user ascertains that the file space is running low during an Export, additional dump files can be added through this API. If the specified dump file already exists for an Export operation and reusefile is not set to 1, an error will be returned.
- For Export operations, the parallelism setting should be less than or equal to the number of dump files in the dump file set. If there are not enough dump files, then the job will not be able to maximize parallelism to the degree specified by the SET_PARALLEL procedure.
- For Import operations, the parallelism setting should also be less than or equal to the number of dump files in the dump file set. If there are not enough dump files, the performance will not be optimal, as multiple threads of execution try to access the same dump file.
- If the substitution variable (%U) is included in a filename, then multiple dump files can be specified through a single call to ADD_FILE. For Export operations, the new dump files will be created as they are needed. Enough dump files will be created to allow all of the processes specified by the current SET_PARALLEL value to be active. If one of the dump files is full, then it is closed, and a new dump file (with a new generated name) is created to take its place. If multiple ADD_FILEs with substitution variables have been specified for dump files in a job, then they will be used to generate dump files in a round-robin fashion. For example, if expa%U, expb%U and expc%U were all specified for a job having a parallelism of 6, then the initial dump files created would appear as follows: expa01, expb01, expc01, expa02, expb02, and expc02.

- If presented with dump file specifications, `expa%U`, `expb%U` and `expc%U`, then an Import or `SQL_FILE` operation will begin by attempting to open the dump files, `expa01`, `expb01`, and `expc01`. If the dump file containing the master table is not found in this set, then the operation will expand its search for dump files by incrementing the substitution variable and looking up the new filenames (for example, `expa02`, `expb02`, and `expc02`). The Oracle Data Pump API will keep expanding the search until it locates the dump file containing the master table. If the Oracle Data Pump API determines that the dump file does not exist, or that it is not part of the current dump set at any iteration, then the Oracle Data Pump API stops incrementing the substitution variable for the dump file specification that was in error. After the master table is found, the master table is used to ascertain when all of dump files in the dump file set have been located.

Examples

> **Note:**
>
> The examples in this section assume that the credentials, network ACLs, database account, and object-store information are already set up.

Example 1

The following example performs a table mode export to the Oracle Object Store.

```
CONNECT user;
Enter password: password

SET SERVEROUTPUT ON
SET ECHO ON
SET FEEDBACK 1
SET NUMWIDTH 10
SET LINESIZE 80
SET TRIMSPOOL ON
SET TAB OFF
SET PAGESIZE 100

DECLARE

        END;
END;
/
EXIT;
```

54.5.2 ATTACH Function

This function provides access to a previously created job.

Syntax

```
DBMS_DATAPUMP.ATTACH(
   job_name    IN VARCHAR2 DEFAULT NULL,
   job_owner    IN VARCHAR2 DEFAULT NULL)
 RETURN NUMBER;
```

Parameters

Table 54-4 ATTACH Function Parameters

Parameter	Description
job_name	The name of the job. The default is the job name owned by the user who is specified in the job_owner parameter (assuming that user has only one job in the Defining, Executing, or Idling states).
job_owner	The user who originally started the job. If NULL, then the value defaults to the owner of the current session. To specify a job owner other than yourself, you must have either the DATAPUMP_EXP_FULL_DATABASE role (for export operations) or the DATAPUMP_IMP_FULL_DATABASE role (for import and SQL_FILE operations). Being a privileged user allows you to monitor another user's job, but you cannot restart another user's job.

Return Values

An opaque handle for the job. This handle is used as input to the following procedures: ADD_FILE, DATA_FILTER, DETACH, GET_STATUS, LOG_ENTRY, METADATA_FILTER, METADATA_REMAP, METADATA_TRANSFORM, SET_PARALLEL, SET_PARAMETER, START_JOB, STOP_JOB, and WAIT_FOR_JOB.

Exceptions

- INVALID_ARGVAL. An invalid value was supplied for an input parameter.
- OBJECT_NOT_FOUND. The specified job no longer exists or the user specified a job owned by another schema, but the user did not have the DATAPUMP_EXP_FULL_DATABASE or DATAPUMP_IMP_FULL_DATABASE role.
- SUCCESS_WITH_INFO. The function succeeded, but further information is available through the GET_STATUS procedure.
- NO_SUCH_JOB. The specified job does not exist.

Usage Notes

- If the job was in the Stopped state, then the job is placed into the Idling state. After the ATTACH succeeds, you can monitor the progress of the job or control the job. The stream of KU$_STATUS_WIP and KU$_STATUS_JOB_ERROR messages returned through the GET_STATUS procedure will be returned to the newly attached job starting at the approximate time of the client's attachment. There will be no repeating of status and error messages that were processed before the client attached to a job.

- If you want to perform a second attach to a job, then you must do so from a different session.
- If the ATTACH fails, then use a null handle in a subsequent call to GET_STATUS for more information about the failure.

54.5.3 DATA_FILTER Procedures

This procedure specifies restrictions on the rows that are to be retrieved.

Syntax

```
DBMS_DATAPUMP.DATA_FILTER (
   handle      IN NUMBER,
   name        IN VARCHAR2,
   value       IN NUMBER,
   table_name  IN VARCHAR2 DEFAULT NULL,
   schema_name IN VARCHAR2 DEFAULT NULL);

DBMS_DATAPUMP.DATA_FILTER(
   handle      IN NUMBER,
   name        IN VARCHAR2,
   value       IN VARCHAR2,
   table_name  IN VARCHAR2 DEFAULT NULL,
   schema_name IN VARCHAR2 DEFAULT NULL);

DBMS_DATAPUMP.DATA_FILTER(
   handle      IN NUMBER,
   name        IN VARCHAR2,
   value       IN CLOB,
   table_name  IN VARCHAR2 DEFAULT NULL,
   schema_name IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 54-5 DATA_FILTER Procedure Parameters

Parameter	Description
handle	The handle that is returned from the OPEN function
name	The name of the filter
value	The value of the filter
table_name	The name of the table on which the data filter is applied. If no table name is supplied, the filter applies to all tables in the job.
schema_name	The name of the schema that owns the table on which the filter is applied. If no schema name is specified, the filter applies to all schemas in the job. If you supply a schema name you must also supply a table name.

Exceptions

- INVALID_ARGVAL. There can be several reasons for this message:
  - A bad filter name is specified
  - The mode is TRANSPORTABLE, which does not support data filters
  - The specified table does not exist

  - The filter has already been set for the specified values of `schema_name` and `table_name`

- `INVALID_STATE`. The user called `DATA_FILTER` when the job was not in the Defining state.
- `INCONSISTENT_ARGS`. The `value` parameter is missing or its datatype does not match the filter name. Or a schema name was supplied, but not a table name.
- `PRIVILEGE_ERROR`. A schema name was supplied, but the user did not have the `DATAPUMP_EXP_FULL_DATABASE` or `DATAPUMP_IMP_FULL_DATABASE` role.
- `SUCCESS_WITH_INFO`. The procedure succeeded, but further information is available through the `GET_STATUS` procedure.
- `NO_SUCH_JOB`. The specified job does not exist.

Usage Notes

- Each data filter can only appear once in each table (for example, you cannot supply multiple `SUBQUERY` filters to a table) or once in each job. If different filters using the same name are applied to both a particular table and to the whole job, the filter parameter supplied for the specific table will take precedence.

  With the exception of the `INCLUDE_ROWS` filter, data filters are not supported on tables having nested tables or domain indexes defined upon them. Data filters are not supported in jobs performed in Transportable Tablespace mode.

  The available data filters are described in Table 54-6.

Table 54-6 Data Filters

Name	Datatype	Operations that Support Filter	Description
`INCLUDE_ROWS`	`NUMBER`	EXPORT, IMPORT	If nonzero, this filter specifies that user data for the specified table should be included in the job. The default is 1.

Table 54-6 (Cont.) Data Filters

Name	Datatype	Operations that Support Filter	Description
PARTITION_EXPR PARTITION_LIST	TEXT	EXPORT, IMPORT	**Note:** In this description, the information about partitions also applies to subpartions. For Export jobs, these filters specify which partitions are unloaded from the database. For Import jobs, they specify which table partitions are loaded into the database. Partition names are included in the job if their names satisfy the specified expression (for PARTITION_EXPR) or are included in the list (for PARTITION_LIST). Whereas the expression version of the filter offers more flexibility, the list version provides for full validation of the partition names. Double quotation marks around partition names are required only if the partition names contain special characters. PARTITION_EXPR is not supported on jobs across a network link. Default=All partitions are processed
SAMPLE	NUMBER	EXPORT, IMPORT	For Export jobs, specifies a percentage for sampling the data blocks to be moved. This filter allows subsets of large tables to be extracted for testing purposes.
SUBQUERY	TEXT	EXPORT, IMPORT	Specifies a subquery that is added to the end of the SELECT statement for the table. If you specify a WHERE clause in the subquery, you can restrict the rows that are selected. Specifying an ORDER BY clause orders the rows dumped in the export which improves performance when migrating from heap-organized tables to index-organized tables.

54.5.4 DATA_REMAP Procedure

This procedure specifies transformations to be applied to column data as it is exported from, or imported into, a database.

Syntax

```
DBMS_DATAPUMP.DATA_REMAP(
   handle          IN NUMBER,
   name            IN VARCHAR2,
   table_name      IN VARCHAR2,
   column          IN VARCHAR2,
   remap_function  IN VARCHAR2,
   schema          IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 54-7 DATA_REMAP Procedure Parameters

Parameter	Description
handle	The handle of the current job. The current session must have previously attached to the handle through a call to an OPEN function.
name	The name of the remap
table_name	The table containing the column to be remapped
column	The name of the column to be remapped
remap_function	The meaning of remap_function is dependent upon the value of name. See Table 54-8 for a list of possible names.
schema	The schema containing the column to be remapped. If NULL, the remapping applies to all schemas moved in the job that contain the specified table.

Exceptions

- INVALID_ARGVAL. The mode is transportable (which does not support data modifications) or it has specified that no data to be included in the job. An invalid remap name was supplied.
- INVALID_OPERATION. Data remaps are only supported for Export and Import operations.
- INVALID_STATE. The DATA_REMAP procedure was called after the job started (that is, it was not in the defining state).
- NO_SUCH_JOB. The job handle is no longer valid.

Usage Notes

- The DATA_REMAP procedure is only supported for Export and Import operations. It allows you to manipulate user data being exported or imported. The name of the remap determines the remap operation to be performed.
- For export operations, you might wish to define a data remap to obscure sensitive data such as credit card numbers from a dump file, but leave the remainder of the data so that it can be read. To accomplish this, the remapping should convert each

unique source number into a distinct generated number. So that the mapping is consistent across the dump file set, the same function should be called for every column that contains the credit card number.

- For import operations, you might wish to define a data remap to reset the primary key when data is being merged into an existing table that contains colliding primary keys. A single remapping function should be provided for all columns defining or referencing the primary key to ensure that remapping is consistent.

> **Note:**
>
> If the called function uses package state variables, then to ensure that remapping is performed consistently across all tables, the job should be run with a SET_PARALLEL value of 1 and no restart operations should be performed.

The Data Remap functions are listed in Table 54-8.

Table 54-8 Names of Data Remap Functions

Name	Meaning of `remap_function`	Meaning
`COLUMN_FUNCTION`	String having the format: `[schema.]package.function`	The `name` parameter references a PL/SQL package function which is called to modify the data for the specified column. The function accepts a single parameter, which has the same datatype as the remapped column, and returns a value having the same datatype as the remapped column. Note that the default for the schema is the schema of the user performing the export.

54.5.5 DETACH Procedure

This procedure specifies that the user has no further interest in using the handle.

Syntax

```
DBMS_DATAPUMP.DETACH(
   handle  IN NUMBER);
```

Parameters

Table 54-9 DETACH Procedure Parameters

Parameter	Description
`handle`	The handle of the job. The current session must have previously attached to the handle through a call to either an `OPEN` or `ATTACH` function.

Exceptions

- INVALID_HANDLE. The specified handle is not attached to a Data Pump job.
- SUCCESS_WITH_INFO. The procedure succeeded, but further information is available through the GET_STATUS procedure.
- NO_SUCH_JOB. The specified job does not exist.

Usage Notes

- Through this call, you specify that you have no further interest in using the handle. Resources associated with a completed job cannot be reclaimed until all users are detached from the job. An implicit detach from a handle is performed when the user's session is exited or aborted. An implicit detach from a handle is also performed upon the expiration of the timeout associated with a STOP_JOB that was applied to the job referenced by the handle. All previously allocated DBMS_DATAPUMP handles are released when an instance is restarted.

54.5.6 GET_DUMPFILE_INFO Procedure

This procedure retrieves information about a specified dump file.

Syntax

```
DBMS_DATAPUMP.GET_DUMPFILE_INFO(
   filename    IN VARCHAR2,
   directory   IN VARCHAR2,
   info_table  OUT ku$_dumpfile_info,
   filetype    OUT NUMBER);
```

Parameters

Table 54-10 GET_DUMPFILE_INFO Procedure Parameters

Parameter	Description
filename	A simple filename with no directory path information
directory	A directory object that specifies where the file can be found
info_table	A PL/SQL table for storing information about the dump file
filetype	The type of file (Data Pump dump file, original Export dump file, external tables dump file, or unknown)

Exceptions

The GET_DUMPFILE_INFO procedure is a utility routine that operates outside the context of any Data Pump job. Exceptions are handled differently for this procedure than for procedures associated in some way with a Data Pump job. A full exception stack should be available directly, without the need to call the GET_STATUS procedure to retrieve the detailed information. The exception for this procedure is as follows:

- NO_DUMPFILE_INFO. Unable to retrieve dump file information as specified.

Usage Notes

You can use the GET_DUMPFILE_INFO procedure to request information about a specific file. If the file is not recognized as any type of dump file, then a filetype of 0 (zero) is returned and the dump file info_table remains empty.

A filetype value of 1 indicates a Data Pump dump file. A filetype value of 2 indicates an original Export dump file. A filetype value of 3 indicates an external tables dump file. In all cases, the dump file info_table will be populated with information retrieved from the dump file header. Rows of this table consist of item code and value pairs, where the item code indicates the type of information and the value column is a VARCHAR2 containing the actual data (converted to a string in some cases). The table is defined as follows:

```
CREATE TYPE sys.ku$_dumpfile_item IS OBJECT (
                item_code       NUMBER,           -- Identifies header item
                value           VARCHAR2(2048)    -- Text string value)/

GRANT EXECUTE ON sys.ku$_dumpfile_item TO PUBLIC;
CREATE OR REPLACE PUBLIC SYNONYM ku$_dumpfile_item FOR sys.ku$_dumpfile_item;

CREATE TYPE sys.ku$_dumpfile_info AS TABLE OF sys.ku$_dumpfile_item/

GRANT EXECUTE ON sys.ku$_dumpfile_info TO PUBLIC;
CREATE OR REPLACE PUBLIC SYNONYM ku$_dumpfile_info FOR sys.ku$_dumpfile_info;
```

The item codes, which can easily be extended to provide more information as needed, are currently defined as shown in Table 54-11 (prepended with the package name, DBMS_DATAPUMP.). Assume the following with regard to these item codes:

- Unless otherwise stated, all item codes may be returned only for Oracle Data Pump and external tables dump files (filetypes 1 and 3).
- Unless otherwise stated, all item codes have been available since Oracle Database 10*g* Release 2 (10.2).

Table 54-11 Item Codes For the DBMS_DATAPUMP.GET_DUMPFILE_INFO Procedure

Item Code	Description
KU$_DFHDR_FILE_VERSION	The internal file version of the dump file.
KU$_DFHDR_MASTER_PRESENT	If the Data Pump master table is present in the dump file, then the value for this item code is 1; otherwise the value is 0. Returned only for filetype 1.
KU$_DFHDR_GUID	A unique identifier assigned to the Data Pump export job or the external tables unload job that produced the dump file. For a multifile dump set, each file in the set has the same value for this item code.
KU$_DFHDR_FILE_NUMBER	A numeric identifier assigned to the dump file. Each dump file in a multifile dump set has its own identifier, unique only within the dump set.
KU$_DFHDR_CHARSET_ID	A numeric code that represents the character set in use at the source system when the dump file was created. Returned for all filetypes.
KU$_DFHDR_CREATION_DATE	The date and time that the dump file was created.
KU$_DFHDR_FLAGS	Internal flag values.
KU$_DFHDR_JOB_NAME	The name assigned to the export job that created the dump file. Returned only for filetype 1.

Table 54-11 (Cont.) Item Codes For the DBMS_DATAPUMP.GET_DUMPFILE_INFO Procedure

Item Code	Description
KU$_DFHDR_PLATFORM	The operating system name of the source system on which the dump file was created.
KU$_DFHDR_INSTANCE	The instance name of the source system on which the dump file was created.
KU$_DFHDR_LANGUAGE	The language name that corresponds to the character set of the source system where the export dump file was created.
KU$_DFHDR_BLOCKSIZE	The blocksize, in bytes, of the dump file.
KU$_DFHDR_DIRPATH	If direct path mode was used when the dump file was created, then the value for this item code is 1, otherwise the value is 0. Returned only for filetype 2.
KU$_DFHDR_METADATA_COMPRESSED	If the system metadata is stored in the dump file in compressed format, then the value for this item code is 1, otherwise the value is 0. Returned only for filetype 1.
KU$_DFHDR_DB_VERSION	The database job version used to create the dump file. Returned for all filetypes.
KU$_DFHDR_MASTER_PIECE_COUNT	The Data Pump master table may be split into multiple pieces and written to multiple dump files in the set, one piece per file. The value returned for this item code indicates the number of dump files that contain pieces of the master table. The value for this item code is only meaningful if the Data Pump master table is present in the dump file, as indicated by the item code KU$_DFHDR_MASTER_PRESENT. Returned only for filetype 1. Only available since Oracle Database 11*g* Release 1 (11.1).
KU$_DFHDR_MASTER_PIECE_NUMBER	The Data Pump master table may be split into multiple pieces and written to multiple dump files in the set, one piece per file. The value returned for this item code indicates which master table piece is contained in the dump file. The value for this item code is only meaningful if the Data Pump master table is present in the dump file, as indicated by the item code KU$_DFHDR_MASTER_PRESENT. Returned only for filetype 1. Only available since Oracle Database 11*g* Release 1 (11.1).
KU$_DFHDR_DATA_COMPRESSED	If the table data is stored in the dump file in compressed format, then the value for this item code is 1, otherwise the value is 0. Only available since Oracle Database 11*g* Release 1 (11.1).
KU$_DFHDR_METADATA_ENCRYPTED	If the system metadata is stored in the dump file in encrypted format, then the value for this item code is 1, otherwise the value is 0. Returned only for filetype 1. Only available since Oracle Database 11*g* Release 1 (11.1).
KU$_DFHDR_DATA_ENCRYPTED	If the table data is stored in the dump file in encrypted format, then the value for this item code is 1, otherwise the value is 0. Only available since Oracle Database 11*g* Release 1 (11.1).
KU$_DFHDR_COLUMNS_ENCRYPTED	If encrypted column data is stored in the dump file in encrypted format, then the value for this item code is 1, otherwise the value is 0. Returned only for filetype 1. Only available since Oracle Database 11*g* Release 1 (11.1).

Table 54-11 (Cont.) Item Codes For the DBMS_DATAPUMP.GET_DUMPFILE_INFO Procedure

Item Code	Description
KU$_DFHDR_ENCRYPTION_MODE	The encryption mode indicates whether a user-provided password or the Oracle Encryption Wallet was used to encrypt data written to the dump file. The possible values returned for this item code are: • KU$_DFHDR_ENCMODE_NONE No data was written to the dump file in encrypted format. • KU$_DFHDR_ENCMODE_PASSWORD Data was written to the dump file in encrypted format using a provided password. • KU$_DFHDR_ENCMODE_DUAL Data was written to the dump file in encrypted format using both a provided password as well as an Oracle Encryption Wallet. • KU$_DFHDR_ENCMODE_TRANS Data was written to the dump file in encrypted format transparently using an Oracle Encryption Wallet. Only available since Oracle Database 11*g* Release 1 (11.1).
KU$_DFHDR_COMPRESSION_ALG	The compression algorithm used when writing system metadata and/or table data to the dump file in compressed format. The possible values returned for this item code are: • KU$_DFHDR_CMPALG_NONE No data was written to the dump file in compressed format. • KU$_DFHDR_CMPALG_BASIC Data was written to the dump file in compressed format using an internal algorithm. This is the default algorithm used since Oracle Database 10*g* Release 2 (10.2). • KU$_DFHDR_CMPALG_LOW Data was written to the dump file in compressed format using the LOW algorithm. • KU$_DFHDR_CMPALG_MEDIUM Data was written to the dump file in compressed format using the MEDIUM algorithm. • KU$_DFHDR_CMPALG_HIGH Data was written to the dump file in compressed format using the HIGH algorithm. Only available since Oracle Database 12*c* Release 1 (12.1).

54.5.7 GET_STATUS Procedure

This procedure monitors the status of a job or waits for the completion of a job.

Syntax

```
DBMS_DATAPUMP.GET_STATUS(
   handle    IN NUMBER,
   mask      IN BINARY_INTEGER,
   timeout   IN NUMBER DEFAULT NULL,
   job_state OUT VARCHAR2,
   status    OUT ku$_Status);
```

Parameters

Table 54-12 GET_STATUS Procedure Parameters

Parameter	Description
handle	The handle of a job. The current session must have previously attached to the handle through a call to either the OPEN or ATTACH function. A null handle can be used to retrieve error information after OPEN and ATTACH failures.
mask	A bit mask that indicates which of four types of information to return: • KU$_STATUS_WIP • KU$_STATUS_JOB_DESC • KU$_STATUS_JOB_STATUS • KU$_STATUS_JOB_ERROR Each status has a numerical value. You can request multiple types of information by adding together different combinations of values.
timeout	Maximum number of seconds to wait before returning to the user. A value of 0 requests an immediate return. A value of -1 requests an infinite wait. If KU$_STATUS_WIP or KU$_STATUS_JOB_ERROR information is requested and becomes available during the timeout period, then the procedure returns before the timeout period is over.
job_state	Current state of the job. If only the job state is needed, it is much more efficient to use this parameter than to retrieve the full ku$_Status structure.
status	A ku$_Status is returned. The ku$_Status mask indicates what kind of information is included. This could be none if only KU$_STATUS_WIP or KU$_STATUS_JOB_ERROR information is requested and the timeout period expires.

Exceptions

- INVALID_HANDLE. The specified handle is not attached to a Data Pump job.
- INVALID_VALUE. The mask or timeout contains an illegal value.
- SUCCESS_WITH_INFO. The procedure succeeded, but further information is available through the GET_STATUS procedure.
- NO_SUCH_JOB. The specified job does not exist.

Usage Notes

The GET_STATUS procedure is used to monitor the progress of an ongoing job and to receive error notification. You can request various type of information using the mask parameter. The KU$_STATUS_JOB_DESC and KU$_STATUS_JOB_STATUS values are classified as synchronous information because the information resides in the master table. The KU$_STATUS_WIP and KU$_STATUS_JOB_ERROR values are classified as asynchronous because the messages that embody these types of information can be generated at any time by various layers in the Data Pump architecture.

- If synchronous information *only* is requested, the interface will ignore the timeout parameter and simply return the requested information.
- If asynchronous information is requested, the interface will wait a *maximum* of timeout seconds before returning to the client. If a message of the requested asynchronous information type is received, the call will complete prior to timeout

seconds. If synchronous information was also requested, it will be returned whenever the procedure returns.

- If the `job_state` returned by `GET_STATUS` does not indicate a terminating job, it is possible that the job could still terminate before the next call to `GET_STATUS`. This would result in an `INVALID_HANDLE` exception. Alternatively, the job could terminate during the call to `GET_STATUS`, which would result in a `NO_SUCH_JOB` exception. Callers should be prepared to handle these cases.

Error Handling

There are two types of error scenarios that need to be handled using the `GET_STATUS` procedure:

- Errors resulting from other procedure calls: For example, the `SET_PARAMETER` procedure may produce an `INCONSISTENT_ARGS` exception. The client should immediately call `GET_STATUS` with `mask=8` (errors) and `timeout=0`. The returned ku$_Status.error will contain a ku$_LogEntry that describes the inconsistency in more detail.
- Errors resulting from events asynchronous to the client(s): An example might be `Table already exists` when trying to create a table. The `ku$_Status.error` will contain a `ku$_LogEntry` with all error lines (from all processing layers that added context about the error) properly ordered.

After a job has begun, a client's main processing loop will typically consist of a call to `GET_STATUS` with an infinite timeout (-1) "listening" for `KU$_STATUS_WIP` and `KU$_STATUS_JOB_ERROR` messages. If status was requested, then `JOB_STATUS` information will also be in the request.

When the ku$_Status is interpreted, the following guidelines should be used:

- `ku$_Status.ku$_JobStatus.percent_done` refers only to the amount of data that has been processed in a job. Metadata is not considered in the calculation. It is determined using the following formulas:
  - EXPORT or network IMPORT--`(bytes_processed/estimated_bytes) * 100`
  - IMPORT--`(bytes_processed/total_expected_bytes) * 100`
  - SQL_FILE or estimate-only EXPORT--`0.00` if not done or `100.00` if done

  The effects of the `QUERY` and `PARTITION_EXPR` data filters are not considered in computing `percent_done`.

  It is expected that the status returned will be transformed by the caller into more user-friendly status. For example, when percent done is not zero, an estimate of completion time could be produced using the following formula:

  ```
  ((SYSDATE - start time) / ku$_Status.ku$_JobStatus.percent_done) * 100
  ```
- The caller should not use `ku$_Status.ku$_JobStatus.percent_done` for determining whether the job has completed. Instead, the caller should only rely on the state of the job as found in `job_state`.

54.5.8 LOG_ENTRY Procedure

This procedure inserts a message into the log file.

Syntax

```
DBMS_DATAPUMP.LOG_ENTRY(
   handle         IN NUMBER,
   message        IN VARCHAR2
   log_file_only  IN NUMBER DEFAULT 0);
```

Parameters

Table 54-13 LOG_ENTRY Procedure Parameters

Parameter	Description
handle	The handle of a job. The current session must have previously attached to the handle through a call to either the OPEN or ATTACH function.
message	A text line to be added to the log file
log_file_only	Specified text should be written only to the log file. It should not be returned in GET_STATUS work-in-progress (KU$_STATUS_WIP) messages.

Exceptions

- INVALID_HANDLE. The specified handle is not attached to a Data Pump job.
- SUCCESS_WITH_INFO. The procedure succeeded, but further information is available through the GET_STATUS procedure.
- NO_SUCH_JOB. The specified job does not exist.

Usage Notes

The message is added to the log file. If log_file_only is zero (the default), the message is also broadcast as a KU$_STATUS_WIP message through the GET_STATUS procedure to all users attached to the job.

The LOG_ENTRY procedure allows applications to tailor the log stream to match the abstractions provided by the application. For example, the command-line interface supports INCLUDE and EXCLUDE parameters defined by the user. Identifying these values as calls to the underlying METADATA_FILTER procedure would be confusing to users. Instead, the command-line interface can enter text into the log describing the settings for the INCLUDE and EXCLUDE parameters.

Lines entered in the log stream from LOG_ENTRY are prefixed by the string, ";;; "

54.5.9 METADATA_FILTER Procedure

This procedure provides filters that allow you to restrict the items that are included in a job.

Syntax

```
DBMS_DATAPUMP.METADATA_FILTER(
   handle       IN NUMBER,
   name         IN VARCHAR2,
   value        IN VARCHAR2,
   object_path  IN VARCHAR2 DEFAULT NULL);

DBMS_DATAPUMP.METADATA_FILTER(
   handle       IN NUMBER,
   name         IN VARCHAR2,
   value        IN CLOB,
   object_path  IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 54-14 METADATA_FILTER Procedure Parameters

Parameter	Description
handle	The handle returned from the OPEN function
name	The name of the filter. See Table 54-15 for descriptions of the available filters.
value	The value of the filter
object_path	The object path to which the filter applies. If the default is used, the filter applies to all applicable objects. Lists of the object paths supported for each mode are contained in the catalog views for DATABASE_EXPORT_OBJECTS, SCHEMA_EXPORT_OBJECTS, and TABLE_EXPORT_OBJECTS. (Note that the TABLE_EXPORT_OBJECTS view is applicable to both Table and Tablespace mode because their object paths are the same.) For an import operation, object paths reference the mode used to create the dump file rather than the mode being used for the import.

Table 54-15 describes the name, the object type, and the meaning of the filters available with the METADATA_FILTER procedure. The datatype for all the filters is a text expression. All operations support all filters.

Table 54-15 Filters Provided by METADATA_FILTER Procedure

Name	Object Type	Meaning
NAME_EXPR NAME_LIST	Named objects	Defines which object names are included in the job. You use the object type parameter to limit the filter to a particular object type. For Table mode, identifies which tables are to be processed.
SCHEMA_EXPR SCHEMA_LIST	Schema objects	Restricts the job to objects whose owning schema name is satisfied by the expression. For Table mode, only a single SCHEMA_EXPR filter is supported. If specified, it must only specify a single schema (for example, 'IN (''SCOTT'')'). For Schema mode, identifies which users are to be processed.

Table 54-15 (Cont.) Filters Provided by METADATA_FILTER Procedure

Name	Object Type	Meaning
TABLESPACE_EXPR TABLESPACE_LIST	TABLE, CLUSTER, INDEX, ROLLBACK_SEGMENT	Restricts the job to objects stored in a tablespace whose name is satisfied by the expression. For Tablespace mode, identifies which tablespaces are to be processed. If a partition of an object is stored in the tablespace, the entire object is added to the job. For Transportable mode, identifies which tablespaces are to be processed. If a table has a single partition in the tablespace set, all partitions must be in the tablespace set. An index is not included within the tablespace set unless all of its partitions are in the tablespace set. A domain index is not included in the tablespace set unless all of its secondary objects are included in the tablespace set.
INCLUDE_PATH_EXPR INCLUDE_PATH_LIST EXCLUDE_PATH_EXPR EXCLUDE_PATH_LIST	All	Defines which object paths are included in, or excluded from, the job. You use these filters to select only certain object types from the database or dump file set. Objects of paths satisfying the condition are included (INCLUDE_PATH_*) or excluded (EXCLUDE_PATH_*) from the operation. The object_path parameter is not supported for these filters.
EXCLUDE_TABLES	TABLE_EXPORT	Specifies that no tables are to be exported.
VIEWS_AS_TABLES	TABLE_EXPORT	A comma-separated list of views to be exported as tables: [schema_name.]view_name[:table_name] The filter can be called multiple times with multiple values and all values get added to a list. All views on the list are exported as tables.

Exceptions

- INVALID_HANDLE. The specified handle is not attached to a Data Pump job.
- INVALID_ARGVAL. This exception can indicate any of the following conditions:
  - An object_path was specified for an INCLUDE_PATH_EXPR or EXCLUDE_PATH_EXPR filter.
  - The specified object_path is not supported for the current mode.
  - The SCHEMA_EXPR filter specified multiple schemas for a Table mode job.
- INVALID_STATE. The user called the METADATA_FILTER procedure after the job left the defining state.
- INCONSISTENT_ARGS. The filter value is of the wrong datatype or is missing.
- SUCCESS_WITH_INFO. The procedure succeeded but further information is available through the GET_STATUS procedure.
- NO_SUCH_JOB. The specified job does not exist.

Usage Notes

- Metadata filters identify a set of objects to be included or excluded from a Data Pump operation. Except for EXCLUDE_PATH_EXPR and INCLUDE_PATH_EXPR, dependent objects of an identified object will be processed along with the identified object. For example, if an index is identified for inclusion by a filter, grants upon that index will also be included by the filter. Likewise, if a table is excluded by a filter, then indexes, constraints, grants and triggers upon the table will also be excluded by the filter.
- Two versions of each filter are supported: SQL expression and List. The SQL expression version of the filters offer maximum flexibility for identifying objects (for example the use of LIKE to support use of wild cards). The names of the expression filters are as follows:
  - NAME_EXPR
  - SCHEMA_EXPR
  - TABLESPACE_EXPR
  - INCLUDE_PATH_EXPR
  - EXCLUDE_PATH_EXPR

  The list version of the filters allow maximum validation of the filter. An error will be reported if one of the elements in the filter is not found within the source database (for Export and network-based jobs) or is not found within the dump file (for file-based Import and SQLFILE jobs). The names of the list filters are as follows:
  - NAME_LIST
  - SCHEMA_LIST
  - TABLESPACE_LIST
  - INCLUDE_PATH_LIST
  - EXCLUDE_PATH_LIST
- Filters allow a user to restrict the items that are included in a job. For example, a user could request a full export, but without Package Specifications or Package Bodies.
- If multiple filters are specified for a object type, they are implicitly 'ANDed' together (that is, objects participating in the job must pass all of the filters applied to their object types).
- The same filter name can be specified multiple times within a job. For example, specifying NAME_EXPR as '!=''EMP''' and NAME_EXPR as '!=''DEPT''' on a Table mode export would produce a file set containing all of the tables except for EMP and DEPT.

54.5.10 METADATA_REMAP Procedure

This procedure specifies a remapping to be applied to objects as they are processed in the specified job.

Syntax

```
DBMS_DATAPUMP.METADATA_REMAP (
   handle      IN NUMBER,
   name        IN VARCHAR2,
   old_value   IN VARCHAR2,
   value       IN VARCHAR2,
   object_type IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 54-16 METADATA_REMAP Procedure Parameters

Parameter	Description
handle	The handle for the current job. The current session must have previously attached to the handle through a call to the OPEN function.
name	The name of the remap. See Table 54-17 for descriptions of the available remaps.
old_value	Specifies which value in the dump file set should be reset to value
value	The value of the parameter for the remap. This signifies the new value that old_value should be translated into.
object_type	Designates the object type to which the remap applies. The list of object types supported for each mode are contained in the DATABASE_EXPORT_OBJECTS, SCHEMA_EXPORT_OBJECTS, TABLE_EXPORT_OBJECTS, and TABLESPACE_EXPORT_OBJECTS catalog views. By default, the remap applies to all applicable objects within the job. The object_type parameter allows a caller to specify different parameters for different object types within a job. Remaps that explicitly specify an object type override remaps that apply to all object types.

Table 54-17 describes the remaps provided by the METADATA_REMAP procedure.

Table 54-17 Remaps Provided by the METADATA_REMAP Procedure

Name	Datatype	Object Type	Meaning
REMAP_SCHEMA	TEXT	Schema objects	Any schema object in the job that matches the object_type parameter and was located in the old_value schema will be moved to the value schema. Privileged users can perform unrestricted schema remaps. Nonprivileged users can perform schema remaps only if their schema is the target schema of the remap. For example, SCOTT can remap his BLAKE's objects to SCOTT, but SCOTT cannot remap SCOTT's objects to BLAKE.
REMAP_TABLESPACE	TEXT	TABLE, INDEX, ROLLBACK_SEGMENT, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG,TABLE_SPACE	Any storage segment in the job that matches the object_type parameter and was located in the old_value tablespace will be relocated to the value tablespace.

Table 54-17 (Cont.) Remaps Provided by the METADATA_REMAP Procedure

Name	Datatype	Object Type	Meaning
REMAP_DATAFILE	TEXT	LIBRARY, TABLESPACE, DIRECTORY	If old_value and value are both full file specifications, then any data file reference in the job that matches the object_type parameter and that referenced the old_value data file will be redefined to use the value data file. If old_value and value are both directory paths, then any data file reference whose object path matches old_value will have its path substituted with value.
REMAP_TABLE	TEXT	TABLE	Any reference to a table in the job that matches the old_value table name will be replaced with the value table name. The old_value parameter may refer to a partition such as employees.low. This allows names for tables constructed the by PARTITION_OPTIONS=DEPARTITION parameter to be specified by the user.

Exceptions

- INVALID_HANDLE. The specified handle is not attached to a Data Pump job.
- INVALID_ARGVAL. This message can indicate any of the following:
  - The job's mode does not include the specified object_type.
  - The remap has already been specified for the specified old_value and object_type.
- INVALID_OPERATION. Remaps are only supported for SQL_FILE and Import operations. The job's operation was Export, which does not support the use of metadata remaps.
- INVALID_STATE. The user called METADATA_REMAP after the job had started (that is, the job was not in the defining state).
- INCONSISTENT_ARGS. There was no value supplied or it was of the wrong datatype for the remap.
- PRIVILEGE_ERROR. A nonprivileged user attempted to do a REMAP_SCHEMA to a different user's schema or a REMAP_DATAFILE.
- SUCCESS_WITH_INFO. The procedure succeeded, but further information is available through the GET_STATUS procedure.
- NO_SUCH_JOB. The specified job does not exist.

Usage Notes

- The METADATA_REMAP procedure is only supported for Import and SQL_FILE operations. It enables you to apply commonly desired, predefined remappings to the definition of objects as part of the transfer. If you need remaps that are not supported within this procedure, you should do a preliminary SQL_FILE operation to produce a SQL script corresponding to the dump file set. By editing the DDL directly and then executing it, you can produce any remappings that you need.
- Transforms for the DataPump API are a subset of the remaps implemented by the DBMS_METADATA.SET_TRANSFORM_PARAMETER API. Multiple remaps can be defined for a single job. However, each remap defined must be unique according its parameters. That is, two remaps cannot specify conflicting or redundant remaps.

54.5.11 METADATA_TRANSFORM Procedure

This procedure specifies transformations to be applied to objects as they are processed in the specified job.

Syntax

```
DBMS_DATAPUMP.METADATA_TRANSFORM (
   handle      IN NUMBER,
   name        IN VARCHAR2,
   value       IN VARCHAR2,
   object_type IN VARCHAR2 DEFAULT NULL);

DBMS_DATAPUMP.METADATA_TRANSFORM (
   handle      IN NUMBER,
   name        IN VARCHAR2,
   value       IN NUMBER,
   object_type IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 54-18 METADATA_TRANSFORM Procedure Parameters

Parameter	Description
handle	The handle for the current job. The current session must have previously attached to the handle through a call to the OPEN function.
name	The name of the transformation. See Table 54-19 for descriptions of the available transforms.
value	The value of the parameter for the transform
object_type	Designates the object type to which the transform applies. The list of object types supported for each mode are contained in the DATABASE_EXPORT_OBJECTS, SCHEMA_EXPORT_OBJECTS, TABLE_EXPORT_OBJECTS, and TABLESPACE_EXPORT_OBJECTS catalog views. By default, the transform applies to all applicable objects within the job. The object_type parameter allows a caller to specify different transform parameters for different object types within a job. Transforms that explicitly specify an object type override transforms that apply to all object types.

Table 54-19 describes the transforms provided by the METADATA_TRANSFORM procedure.

Table 54-19 Transforms Provided by the METADATA_TRANFORM Procedure

Name	Datatype	Object Type	Meaning
DISABLE_ARCHIVE_LOGGING	NUMBER	TABLE INDEX	Specifies whether to disable archive logging for specified object types during import. A value of zero (FALSE) is the default. It specifies that archive logging will take place. This is the default behavior if this transform parameter is not specified. A non-zero (TRUE) value disables archive logging for the specified object types before data is loaded during import. If no object type is specified, then archive logging is disabled for both TABLE and INDEX object types. All other object types processed during data pump import are logged. **Note:** If the database is in FORCE LOGGING mode, then the DISABLE_ARCHIVE_LOGGING transform does not disable logging when indexes and tables are created.
INMEMORY	NUMBER	TABLE TABLESPACE MATERIALIZED VIEWS	The INMEMORY transform is related to the In-Memory Column Store (IM column store), an optional area in the SGA that stores whole tables, table partitions, and individual columns in a compressed columnar format. If a non-zero value (TRUE) is specified on import, then Data Pump generates an IM clause that preserves the IM setting those objects had at export time. This is the default. If a value of zero (FALSE) is specified on import, then Data Pump does not include an IM clause for any objects. **Note**: The INMEMORY transform is available only in Oracle Database 12*c* Release 1 (12.1.0.2) or higher.
INMEMORY_CLAUSE	TEXT	TABLE TABLESPACE MATERIALIZED VIEWS	The INMEMORY_CLAUSE transform is related to the In-Memory Column Store (IM column store), an optional area in the SGA that stores whole tables, table partitions, and individual columns in a compressed columnar format. When you specify this transform, Data Pump uses the contents of the string as the IM clause for all objects being imported that have an IM clause in their DDL. This transform is useful when you want to override the IM clause for an object in the dump file. **Note**: The INMEMORY_CLAUSE transform is available only in Oracle Database 12*c* Release (12.1.0.2) or higher.

Table 54-19 (Cont.) Transforms Provided by the METADATA_TRANFORM Procedure

Name	Datatype	Object Type	Meaning
LOB_STORAGE	TEXT	TABLE	Specifies the storage type to use for LOB segments. The options are as follows: • SECUREFILE - LOB storage is returned as SECUREFILE • BASICFILE - LOB storage is returned as BASICFILE • DEFAULT - The keyword (SECUREFILE or BASICFILE) is omitted in the LOB STORE AS clause. • NO_CHANGE - LOB segments are created with the same storage they had in the source database. This is the default. Specifying this transform changes the LOB storage for all tables in the job, including tables that provide storage for materialized views.
OID	NUMBER	TYPE TABLE	If zero, inhibits the assignment of the exported OID during type or table creation. Instead, a new OID will be assigned. Use of this transform on Object Tables will cause breakage in REF columns that point to the table. Defaults to 1.
PCTSPACE	NUMBER	TABLE INDEX TABLESPACE	Specifies a percentage multiplier used to alter extent allocations and data file sizes. Used to shrink large tablespaces for testing purposes. Defaults to 100.
SEGMENT_ATTRIBUTES	NUMBER	TABLE, INDEX	If nonzero (TRUE), emit storage segment parameters. Defaults to 1.
SEGMENT_CREATION	NUMBER	TABLE	If nonzero (TRUE), the SQL SEGMENT CREATION clause is added to the CREATE TABLE statement. That is, the CREATE TABLE statement will explicitly say either SEGMENT CREATION DEFERRED or SEGMENT CREATION IMMEDIATE. If the value is FALSE, then the SEGMENT CREATION clause is omitted from the CREATE TABLE statement. Set this parameter to FALSE to use the default segment creation attributes for the table(s) being loaded. Defaults to nonzero (TRUE).
STORAGE	NUMBER	TABLE	If nonzero (TRUE), emit storage clause. (Ignored if SEGMENT_ATTRIBUTES is zero.) Defaults to nonzero (TRUE).

Table 54-19 (Cont.) Transforms Provided by the METADATA_TRANFORM Procedure

Name	Datatype	Object Type	Meaning
TABLE_COMPRESSION_CLAUSE	TEXT	TABLE	Specifies a table compression clause (for example, COMPRESS BASIC) to use when the table is created. Specify NONE to omit the table compression clause. The table will have the default compression for the tablespace. Specifying this transform changes the compression type for all tables in the job, including tables that provide storage for materialized views.

Exceptions

- INVALID_HANDLE. The specified handle is not attached to a Data Pump job.
- INVALID_ARGVAL. This message can indicate any of the following:
  - The mode is transportable, which doesn't support transforms.
  - The job's mode does not include the specified object_type.
  - The transform has already been specified for the specified value and object_type.
- INVALID_OPERATION. Transforms are only supported for SQL_FILE and Import operations. The job's operation was Export which does not support the use of metadata transforms.
- INVALID_STATE. The user called METADATA_TRANSFORM after the job had started (that is, the job was not in the defining state).
- INCONSISTENT_ARGS. There was no value supplied or it was of the wrong datatype for the transform.
- PRIVILEGE_ERROR. A nonprivileged user attempted to do a REMAP_SCHEMA to a different user's schema or a REMAP_DATAFILE.
- SUCCESS_WITH_INFO. The procedure succeeded, but further information is available through the GET_STATUS procedure.
- NO_SUCH_JOB. The specified job does not exist.

Usage Notes

- The METADATA_TRANSFORM procedure is only supported for Import and SQL_FILE operations. It enables you to apply commonly desired, predefined transformations to the definition of objects as part of the transfer. If you need transforms that are not supported within this procedure, you should do a preliminary SQL_FILE operation to produce a SQL script corresponding to the dump file set. By editing the DDL directly and then executing it, you can produce any transformations that you need.
- Transforms for the DataPump API are a subset of the transforms implemented by the DBMS_METADATA.SET_TRANSFORM_PARAMETER API. Multiple transforms can be defined for a single job. However, each transform defined must be unique according its parameters. That is, two transforms cannot specify conflicting or redundant transformations.

54.5.12 OPEN Function

This function is used to declare a new job using the Data Pump API.

> **Note:**
>
> A multitenant container database is the only supported architecture in Oracle Database 20c. While the documentation is being revised, legacy terminology may persist. In most cases, "database" and "non-CDB" refer to a CDB or PDB, depending on context. In some contexts, such as upgrades, "non-CDB" refers to a non-CDB from a previous release.

The handle that is returned is used as a parameter for calls to all other procedures (but not to the `ATTACH` function).

Syntax

```
DBMS_DATAPUMP.OPEN (
   operation    IN VARCHAR2,
   job_mode         IN VARCHAR2,
   remote_link  IN VARCHAR2 DEFAULT NULL,
   job_name     IN VARCHAR2 DEFAULT NULL,
   version      IN VARCHAR2 DEFAULT 'COMPATIBLE')
 RETURN NUMBER;
```

Parameters

Table 54-20 OPEN Function Parameters

Parameter	Meaning
`operation`	The type of operation to be performed. Table 54-21 contains descriptions of valid operation types.
`job_mode`	The scope of the operation to be performed. Table 54-22 contains descriptions of valid modes. Specifying NULL generates an error.
`remote_link`	If the value of this parameter is non-null, it provides the name of a database link to the remote database that will be the source of data and metadata for the current job.
`job_name`	The name of the job. The name is limited to 128 characters; it will be truncated if more than 128 characters are used. It may consist of printable characters and spaces. It is implicitly qualified by the schema of the user executing the `OPEN` function and must be unique to that schema (that is, there cannot be other Data Pump jobs using the same name). The name is used to identify the job both within the API and with other database components such as identifying the job in the `DBA_RESUMABLE` view if the job becomes suspended through lack of resources. If no name is supplied, a system generated name will be provided for the job in the following format: `"SYS_<OPERATION>_<MODE>_%N".` The default job name is formed where `%N` expands to a two-digit incrementing integer starting at '`01`' (for example, "`SYS_IMPORT_FULL_03`"). The name supplied for the job will also be used to name the master table and other resources associated with the job.

Table 54-20 (Cont.) OPEN Function Parameters

Parameter	Meaning
version	The version of database objects to be extracted. This option is only valid for Export, network Import, and SQL_FILE operations. Database objects or attributes that are incompatible with the version will not be extracted. Legal values for this parameter are as follows: • COMPATIBLE - (default) the version of the metadata corresponds to the database compatibility level and the compatibility release level for feature (as given in the V$COMPATIBILITY view). Database compatibility must be set to 9.2 or higher. • LATEST - the version of the metadata corresponds to the database version. • A specific database version, for example, '11.0.0'. Specify a value of 12 to allow all existing database features, components, and options to be exported from Oracle Database 11*g* release 2 (11.2.0.3) or later into an Oracle Database 12 *c* Release 1 (12.1) (either a multitenant container database (CDB) or a non-CDB).

Table 54-21 describes the valid operation types for the OPEN function.

Table 54-21 Valid Operation Types for the OPEN Function

Operation	Description
EXPORT	Saves data and metadata to a dump file set or obtains an estimate of the size of the data for an operation.
IMPORT	Restores data and metadata from a dump file set or across a database link.
SQL_FILE	Displays the metadata within a dump file set, or from across a network link, as a SQL script. The location of the SQL script is specified through the ADD_FILE procedure.

Table 54-22 describes the valid modes for the OPEN function.

Table 54-22 Valid Modes for the OPEN Function

Mode	Description
FULL	Operates on the full database or full dump file set except for Oracle Database internal schemas. (Some tables from Oracle Database internal schemas may be registered to be exported and imported in full operations in order to provide consistent metadata during import.) The TRANSPORTABLE parameter can be set to ALWAYS during a full database export in order to move data via transportable tablespaces rather than in the Data Pump dump file.
SCHEMA	Operates on a set of selected schemas. Defaults to the schema of the current user. All objects in the selected schemas are processed. In SCHEMA mode, you cannot specify Oracle-internal schemas (for example, SYS, XDB, ORDSYS, MDSYS, CTXSYS, ORDPLUGINS, or LBACSYS).

Table 54-22 (Cont.) Valid Modes for the OPEN Function

Mode	Description
TABLE	Operates on a set of selected tables. Defaults to all of the tables in the current user's schema. Only tables and their dependent objects are processed.
TABLESPACE	Operates on a set of selected tablespaces. No defaulting is performed. Tables that have storage in the specified tablespaces are processed in the same manner as in Table mode.
TRANSPORTABLE	Operates on metadata for tables (and their dependent objects) within a set of selected tablespaces to perform a transportable tablespace export/import.

Return Values

- An opaque handle for the job. This handle is used as input to the following procedures: ADD_FILE, CREATE_JOB_VIEW, DATA_FILTER, DETACH, GET_STATUS, LOG_ENTRY, LOG_ERROR, METADATA_FILTER, METADATA_REMAP, METADATA_TRANSFORM, SET_PARALLEL, SET_PARAMETER, START_JOB, STOP_JOB, and WAIT_FOR_JOB

Exceptions

- INVALID_ARGVAL. An invalid operation or mode was specified. A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- JOB_EXISTS. A table already exists with the specified job name.
- PRIVILEGE_ERROR. The user does not have the necessary privileges or roles to use the specified mode.
- INTERNAL_ERROR. The job was created under the wrong schema or the master table was of the wrong format.
- SUCCESS_WITH_INFO. The function succeeded, but further information is available through the GET_STATUS procedure.
- NO_SUCH_JOB. The specified job does not exist.

Usage Notes

- When the job is created, a master table is created for the job under the caller's schema within the caller's default tablespace. A handle referencing the job is returned that attaches the current session to the job. Once attached, the handle remains valid until either an explicit or implicit detach occurs. The handle is only valid in the caller's session. Other handles can be attached to the same job from a different session by using the ATTACH function.
- If the call to the OPEN function fails, call the GET_STATUS procedure with a null handle to retrieve additional information about the failure.

54.5.13 SET_PARALLEL Procedure

This procedure adjusts the degree of parallelism within a job.

Syntax

```
DBMS_DATAPUMP.SET_PARALLEL(
   handle      IN NUMBER,
   degree      IN NUMBER);
```

Parameters

Table 54-23 SET_PARALLEL Procedure Parameters

Parameter	Description
handle	The handle of a job. The current session must have previously attached to the handle through a call to either the OPEN or ATTACH function.
degree	The maximum number of worker processes that can be used for the job. You use this parameter to adjust the amount of resources used for a job.

Exceptions

- INVALID_HANDLE. The specified handle is not attached to a Data Pump job.
- INVALID_OPERATION. The SET_PARALLEL procedure is only valid for export and import operations.
- INVALID_ARGVAL. An invalid value was supplied for an input parameter.
- SUCCESS_WITH_INFO. The procedure succeeded, but further information is available through the GET_STATUS procedure.
- NO_SUCH_JOB. The specified job does not exist.

Usage Notes

- The SET_PARALLEL procedure is only available in the Enterprise Edition of the Oracle database.
- The SET_PARALLEL procedure can be executed by any session attached to a job. The job must be in one of the following states: Defining, Idling, or Executing.
- The effect of decreasing the degree of parallelism may be delayed because ongoing work needs to find an orderly completion point before SET_PARALLEL can take effect.
- Decreasing the parallelism will not result in fewer worker processes associated with the job. It will only decrease the number of worker processes that will be executing at any given time.
- Increasing the parallelism will take effect immediately if there is work that can be performed in parallel.
- The degree of parallelism requested by a user may be decreased based upon settings in the resource manager or through limitations introduced by the PROCESSES or SESSIONS initialization parameters in the init.ora file.

- To parallelize an Export job to a degree of *n*, the user should supply *n* files in the dump file set or specify a substitution variable in a file specification. Otherwise, some of the worker processes will be idle while waiting for files.
- SQL_FILE operations always operate with a degree of 1. Jobs running in the Transportable mode always operate with a degree of 1.

54.5.14 SET_PARAMETER Procedures

This procedure is used to specify job-processing options.

Syntax

```
DBMS_DATAPUMP.SET_PARAMETER(
   handle       IN NUMBER,
   name         IN VARCHAR2,
   value        IN VARCHAR2);

DBMS_DATAPUMP.SET_PARAMETER (
   handle      IN NUMBER,
   name        IN VARCHAR2,
   value       IN NUMBER);
```

Parameters

Table 54-24 SET_PARAMETER Procedure Parameters

Parameter	Description
handle	The handle of a job. The current session must have previously attached to the handle through a call to the OPEN function.
name	The name of the parameter. Table 54-25 describes the valid parameter names.
value	The value for the specified parameter

Table 54-25 describes the valid options for the name parameter of the SET_PARAMETER procedure.

Table 54-25 Valid Options for the name Parameter in the SET_PARAMETER Procedure

Parameter Name	Datatype	Supported Operations	Meaning
CLIENT_COMMAND	TEXT	All	An opaque string used to describe the current operation from the client's perspective. The command-line procedures will use this string to store the original command used to invoke the job.

Table 54-25 (Cont.) Valid Options for the name Parameter in the SET_PARAMETER Procedure

Parameter Name	Datatype	Supported Operations	Meaning
COMPRESSION	TEXT	Export	Allows you to trade off the size of the dump file set versus the time it takes to perform export and import operations. The DATA_ONLY option compresses only user data in the dump file set. The METADATA_ONLY option compresses only metadata in the dump file set. The ALL option compresses both user data and metadata. The NONE option stores the dump file set in an uncompressed format. The METADATA_ONLY and NONE options require a job version of 10.2 or later. All other options require a job version of 11.1 or later. Default=METADATA_ONLY
COMPRESSION_ALGORITHM	TEXT	Export	Indicates the compression algorithm is to be used when compressing dump file data. The choices are as follows: • BASIC--Offers a good combination of compression ratios and speed; the algorithm used is the same as in previous versions of Oracle Data Pump. • LOW---Least impact on backup throughput and suited for environments where CPU resources are the limiting factor. • MEDIUM---Recommended for most environments. This option, like the BASIC option, provides a good combination of compression ratios and speed, but it uses a different algorithm than BASIC. • HIGH--Best suited for exports over slower networks where the limiting factor is network speed. To use this feature, the COMPATIBLE initialization parameter must be set to at least 12.0.0. This feature requires that the Oracle Advanced Compression option be enabled.
DATA_ACCESS_METHOD	TEXT	Export and Import	Allows you to specify an alternative method to unload data if the default method does not work for some reason. The choices are AUTOMATIC, DIRECT_PATH, or EXTERNAL_TABLE. Oracle recommends that you use the default option (AUTOMATIC) whenever possible because it allows Data Pump to automatically select the most efficient method.

Table 54-25 (Cont.) Valid Options for the name Parameter in the SET_PARAMETER Procedure

Parameter Name	Datatype	Supported Operations	Meaning
DATA_OPTIONS	Number	Export and Import	A bitmask to supply special options for processing the job. The possible values are as follows: • KU$_DATAOPT_SKIP_CONST_ERR • KU$_DATAOPT_XMLTYPE_CLOB • KU$_DATAOPT_DISABL_APPEND_HINT KU$_DATAOPT_GRP_PART_TAB • KU$_DATAOPT_TRUST_EXIST_TB_PAR • KU$_DATAOPT_CONT_LOAD_ON_FMT_ERR Export supports the value KU$_DATAOPT_XMLTYPE_CLOB. This option stores compressed XMLType columns in the dump file in CLOB format rather than as XML documents. **Note**: XMLType stored as CLOB is deprecated as of Oracle Database 12c Release 1 (12.1). Import supports the value KU$_DATAOPT_SKIP_CONST_ERR. This option specifies that if constraint violations occur while data is being imported into user tables, the rows that cause the violations will be rejected and the load will continue. If this option is not set, a constraint error will abort the loading of the entire partition (or table for unpartitioned tables). Setting this option may affect performance, especially for pre-existing tables with unique indexes or constraints. Import also supports the value KU$_DATAOPT_DISABL_APPEND_HINT. This option prevents the append hint from being applied to the data load. Disabling the APPEND hint can be useful if there is a small set of data objects to load that already exist in the database and some other application may be concurrently accessing one or more of the data objects. Data Pump Export supports the value KU$_DATAOPT_GRP_PART_TAB. This option tells Data Pump to unload all table data in one operation rather than unload each table partition as a separate operation. As a result, the definition of the table will not matter at import time because Import will see one partition of data that will be loaded into the entire table. Data Pump Import supports the value KU$_DATAOPT_TRUST_EXIST_TB_PAR. This option tells Data Pump to load partition data in parallel into existing tables. Use of the DATA_OPTIONS parameter requires that the version on the OPEN function be set to 11.1 or later. Default=0 Data Pump Import supports the value KU$_DATAOPT_CONT_LOAD_ON_FMT_ERR. This option tells Data Pump to skip forward to the start of the next granule if a stream format error is encountered while loading table data. Most stream format errors are caused by corrupt dump files. This value can be used if Data Pump encounters a stream format error and the original export database is not available to export the table data again. If Data Pump skips over data, not all data

Table 54-25 (Cont.) Valid Options for the name Parameter in the SET_PARAMETER Procedure

Parameter Name	Datatype	Supported Operations	Meaning
			from the source database is imported potentially skipping hundreds or thousands of rows.
ENCRYPTION	TEXT	Export	Specifies what to encrypt in the dump file set, as follows: ALL enables encryption for all data and metadata in the export operation. DATA_ONLY specifies that only data is written to the dump file set in encrypted format. ENCRYPTED_COLUMNS_ONLY specifies that only encrypted columns are written to the dump file set in encrypted format. METADATA_ONLY specifies that only metadata is written to the dump file set in encrypted format. NONE specifies that no data is written to the dump file set in encrypted format. This parameter requires a job version of 11.1 or later. The default value depends upon the combination of encryption-related parameters that are used. To enable encryption, either ENCRYPTION or ENCRYPTION_PASSWORD or both, must be specified. If only ENCRYPTION_PASSWORD is specified, then ENCRYPTION defaults to ALL. If neither ENCRYPTION nor ENCRYPTION_PASSWORD is specified, then ENCRYPTION defaults to NONE. To specify ALL, DATA_ONLY, or METADATA_ONLY, the COMPATIBLE initialization parameter must be set to at least 11.1. **NOTE**: If the data being exported includes SecureFiles that you want to be encrypted, then you must specify ENCRYPTION=ALL to encrypt the entire dump file set. Encryption of the entire dump file set is the only way to achieve encryption security for SecureFiles during a Data Pump export operation.
ENCRYPTION_ALGORITHM	TEXT	Export	Identifies which cryptographic algorithm should be used to perform encryption. Possible values are AES128, AES192, and AES256. The ENCRYPTION_ALGORITHM parameter requires that you also specify either ENCRYPTION or ENCRYPTION_PASSWORD; otherwise an error is returned. See *Oracle Database Advanced Security Guide* for information about encryption algorithms. This parameter requires a job version of 11.1 or later. Default=AES128

Table 54-25 (Cont.) Valid Options for the name Parameter in the SET_PARAMETER Procedure

Parameter Name	Datatype	Supported Operations	Meaning
ENCRYPTION_MODE	TEXT	Export	Identifies the types of security used for encryption and decryption. The values are as follows: PASSWORD requires that you provide a password when creating encrypted dump file sets. You will need to provide the same password when you import the dump file set. PASSWORD mode requires that you also specify the ENCRYPTION_PASSWORD parameter. The PASSWORD mode is best suited for cases in which the dump file set will be imported into a different or remote database, but which must remain secure in transit. TRANSPARENT allows an encrypted dump file set to be created without any intervention from a database administrator (DBA), provided the required Oracle Encryption Wallet is available. Therefore, the ENCRYPTION_PASSWORD parameter is not required, and will in fact, cause an error if it is used in TRANSPARENT mode. This encryption mode is best suited for cases in which the dump file set will be imported into the same database from which it was exported. DUAL creates a dump file set that can later be imported using either the Oracle Encryption Wallet or the password that was specified with the ENCRYPTION_PASSWORD parameter. DUAL mode is best suited for cases in which the dump file set will be imported on-site using the Oracle Encryption Wallet, but which may also need to be imported offsite where the Oracle Encryption Wallet is not available. When you use the ENCRYPTION_MODE parameter, you must also use either the ENCRYPTION or ENCRYPTION_PASSWORD parameter. Otherwise, an error is returned. To use DUAL or TRANSPARENT mode, the COMPATIBLE initialization parameter must be set to at least 11.1. The default mode depends on which other encryption-related parameters are used. If only ENCRYPTION is specified, then the default mode is TRANSPARENT. If ENCRYPTION_PASSWORD is specified and the Oracle Encryption Wallet is open, then the default is DUAL. If ENCRYPTION_PASSWORD is specified and the Oracle Encryption Wallet is closed, then the default is PASSWORD.
ENCRYPTION_PASSWORD	TEXT	Export and Import	For export operations, this parameter is required if ENCRYPTION_MODE is set to either PASSWORD or DUAL. It is also required for transportable export/import operations (job mode=FULL and TRANSPORTABLE=ALWAYS) when the database includes either encrypted tablespaces or tables with encrypted columns.

Table 54-25 (Cont.) Valid Options for the name Parameter in the SET_PARAMETER Procedure

Parameter Name	Datatype	Supported Operations	Meaning
ESTIMATE	TEXT	Export and Import	Specifies that the estimate method for the size of the tables should be performed before starting the job. If BLOCKS, a size estimate for the user tables is calculated using the count of blocks allocated to the user tables. If STATISTICS, a size estimate for the user tables is calculated using the statistics associated with each table. If no statistics are available for a table, the size of the table is estimated using BLOCKS. The ESTIMATE parameter cannot be used in Transportable Tablespace mode. Default=STATISTICS
ESTIMATE_ONLY	NUMBER	Export	Specifies that only the estimation portion of an export job should be performed. This option is useful for estimating the size of dump files when the size of the export is unknown.
FLASHBACK_SCN	NUMBER	Export and network Import	System change number (SCN) to serve as transactionally consistent point for reading user data. If neither FLASHBACK_SCN nor FLASHBACK_TIME is specified, there will be no transactional consistency between partitions, except for logical standby databases and Streams targets. FLASHBACK_SCN is not supported in Transportable mode. For FLASHBACK_SCN, Data Pump supports the new 8–byte big SCNs used in Oracle Database 12*c* release 2 (12.2).
FLASHBACK_TIME	TEXT	Export and network Import	Either the date and time used to determine a consistent point for reading user data or a string of the form TO_TIMESTAMP(...). If neither FLASHBACK_SCN nor FLASHBACK_TIME is specified, there will be no transactional consistency between partitions. FLASHBACK_SCN and FLASHBACK_TIME cannot both be specified for the same job. FLASHBACK_TIME is not supported in Transportable mode.
INCLUDE_METADATA	NUMBER	Export and Import	If nonzero, metadata for objects will be moved in addition to user table data. If zero, metadata for objects will not moved. This parameter converts an Export operation into an unload of user data and an Import operation into a load of user data. INCLUDE_METADATA is not supported in Transportable mode. Default=1
KEEP_MASTER	NUMBER	Export and Import	Specifies whether the master table should be deleted or retained at the end of a Data Pump job that completes successfully. The master table is automatically retained for jobs that do not complete successfully. Default=0.

Table 54-25 (Cont.) Valid Options for the name Parameter in the SET_PARAMETER Procedure

Parameter Name	Datatype	Supported Operations	Meaning
LOGTIME	TEXT	Export and Import	Specifies that messages displayed during export and import operations be timestamped. Valid options are as follows: • NONE--No timestamps on status or log file messages (this is the default) • STATUS--Timestamps on status messages only • LOGFILE--Timestamps on log file messages only • ALL--Timestamps on both status and log file messages
MASTER_ONLY	NUMBER	Import	Indicates whether to import just the master table and then stop the job so that the contents of the master table can be examined. Default=0.
METRICS	NUMBER	Export and Import	Indicates whether additional information about the job should be reported to the Data Pump log file. Default=0.
PARTITION_OPTIONS	TEXT	Import	Specifies how partitioned tables should be handled during an import operation. The options are as follows: NONE means that partitioning is reproduced on the target database as it existed in the source database. DEPARTITION means that each partition or subpartition that contains storage in the job is reproduced as a separate unpartitioned table. Intermediate partitions that are subpartitioned are not re-created (although their subpartitions are converted into tables). The names of the resulting tables are system-generated from the original table names and partition names unless the name is overridden by the REMAP_TABLE metadata transform. MERGE means that each partitioned table is re-created in the target database as an unpartitioned table. The data from all of the source partitions is merged into a single storage segment. This option is not supported for transportable jobs or when the TRANSPORTABLE parameter is set to ALWAYS. This parameter requires a job version of 11.1 or later. Default=NONE
REUSE_DATAFILES	NUMBER	Import	Specifies whether the import job should reuse existing data files for tablespace creation. Default=0.
SKIP_UNUSABLE_INDEXES	NUMBER	Import	If nonzero, rows will be inserted into tables having unusable indexes. SKIP_UNUSABLE_INDEXES is not supported in Transportable mode. Default=1
SOURCE_EDITION	TEXT	Export and network Import	The application edition that will be used for determining the objects that will be unloaded for export and for network import.
STREAMS_CONFIGURATION	NUMBER	Import	Specifies whether to import any Streams metadata that may be present in the export dump file. Default=1.

Table 54-25 (Cont.) Valid Options for the name Parameter in the SET_PARAMETER Procedure

Parameter Name	Datatype	Supported Operations	Meaning
TABLE_EXISTS_ACTION	TEXT	Import	Specifies the action to be performed when data is loaded into a preexisting table. The possible actions are: TRUNCATE, REPLACE, APPEND, and SKIP. If INCLUDE_METADATA=0, only TRUNCATE and APPEND are supported. If TRUNCATE, rows are removed from a preexisting table before inserting rows from the Import. Note that if TRUNCATE is specified on tables referenced by foreign key constraints, the TRUNCATE will be modified into a REPLACE. If REPLACE, preexisting tables are replaced with new definitions. Before creating the new table, the old table is dropped. If APPEND, new rows are added to the existing rows in the table. If SKIP, the preexisting table is left unchanged. TABLE_EXISTS_ACTION is not supported in Transportable mode. The default is SKIP if metadata is included in the import. The default is APPEND if INCLUDE_METADATA is set to 0.
TABLESPACE_DATAFILE	TEXT	Import	Specifies the full file specification for a data file in the transportable tablespace set. TABLESPACE_DATAFILE is only valid for transportable mode imports. TABLESPACE_DATAFILE can be specified multiple times, but the value specified for each occurrence must be different.
TARGET_EDITION	TEXT	Import	The application edition that will be used for determining where the objects will be loaded for import and for network import.

Table 54-25 (Cont.) Valid Options for the name Parameter in the SET_PARAMETER Procedure

Parameter Name	Datatype	Supported Operations	Meaning
TRANSPORTABLE	TEXT	Export (and network import or full-mode import)	This option is for export operations done in table mode, and also for full-mode imports and network imports. It allows the data to be moved using transportable tablespaces. In table-mode storage segments in the moved tablespaces that are not associated with the parent schemas (tables) will be reclaimed at import time. If individual partitions are selected in a table-mode job, only the tablespaces referenced by those partitions will be moved. During import, the moved partitions can only be reconstituted as tables by using the PARTITION_OPTIONS=DEPARTITION parameter. Use of the TRANSPORTABLE parameter prohibits the subsequent import of the dump file into a database at a lower version or using different character sets. Additionally, the data files may need to be converted if the target database is on a different platform. In table-mode, the TRANSPORTABLE parameter is not allowed if a network link is supplied on the OPEN call. The possible values for this parameter are as follows: ALWAYS - data is always moved by moving data files. This option is valid only for table mode and full mode. NEVER - data files are never used for copying user data This parameter requires a job version of 11.1 or later This parameter requires a job version of 12.1 or later when the job mode is FULL. Default=NEVER
TTS_FULL_CHECK	NUMBER	Export	If nonzero, verifies that a transportable tablespace set has no dependencies (specifically, IN pointers) on objects outside the set, and vice versa. Only valid for Transportable mode Exports. Default=0
USER_METADATA	NUMBER	Export and network Import	For schema-mode operations, specifies that the metadata to re-create the users' schemas (for example, privilege grants to the exported schemas) should also be part of the operation if set to nonzero. Users must be privileged to explicitly set this parameter. The USER_METADATA parameter cannot be used in Table, Tablespace, or Transportable Tablespace mode. Default=1 if user has DATAPUMP_EXP_FULL_DATABASE role; 0 otherwise.

Exceptions

- INVALID_HANDLE. The specified handle is not attached to a Data Pump job.
- INVALID_ARGVAL. This exception could be due to any of the following causes:
  - An invalid name was supplied for an input parameter
  - The wrong datatype was used for value
  - A value was not supplied

  - The supplied value was not allowed for the specified parameter name
  - A flashback parameter had been established after a different flashback parameter had already been established
  - A parameter was specified that did not support duplicate definitions
- INVALID_OPERATION. The operation specified is invalid in this context.
- INVALID_STATE. The specified job is not in the Defining state.
- INCONSISTENT_ARGS. Either the specified parameter is not supported for the current operation type or it is not supported for the current mode.
- PRIVILEGE_ERROR. The user does not have the DATAPUMP_EXP_FULL_DATABASE or DATAPUMP_IMP_FULL_DATABASE role required for the specified parameter.
- SUCCESS_WITH_INFO. The procedure succeeded, but further information is available through the GET_STATUS procedure.
- NO_SUCH_JOB. The specified job does not exist.

Usage Notes

- The SET_PARAMETER procedure is used to specify optional features for the current job. See Table 54-25 for a list of supported options.

54.5.15 START_JOB Procedure

This procedure begins or resumes job execution.

Syntax

```
DBMS_DATAPUMP.START_JOB (
   handle       IN NUMBER,
   skip_current    IN  NUMBER DEFAULT 0,
   abort_step      IN  NUMBER DEFAULT 0,
   cluster_ok      IN  NUMBER DEFAULT 1,
   service_name    IN  VARCHAR2 DEFAULT NULL);
```

Parameters

Table 54-26 START_JOB Procedure Parameters

Parameter	Description
handle	The handle of a job. The current session must have previously attached to the handle through a call to either the OPEN or ATTACH function.
skip_current	If nonzero, causes actions that were 'in progress' on a previous execution of the job to be skipped when the job restarts. The skip will only be honored for Import jobs. This mechanism allows the user to skip actions that trigger fatal bugs and cause the premature termination of a job. Multiple actions can be skipped on a restart. The log file will identify which actions are skipped. If a domain index was being processed, all pieces of the domain index are skipped even if the error occurred in only a subcomponent of the domain index. A description of the actions skipped is entered into the log file. skip_current is ignored for the initial START_JOB in a job. If zero, no data or metadata is lost upon a restart.

Table 54-26 (Cont.) START_JOB Procedure Parameters

Parameter	Description
abort_step	Value must be 0. Inserting values other than 0 into this argument will have unintended consequences.
cluster_ok	If = 0, all workers are started on the current instance. Otherwise, workers are started on instances usable by the job.
service_name	If specified, indicates a service name used to constrain the job to specific instances or to a specific resource group.

Exceptions

- INVALID_HANDLE. The specified handle is not attached to a Data Pump job.
- INVALID_STATE. The causes of this exception can be any of the following:
  - No files have been defined for an Export, non-network Import, or SQL_FILE job
  - An ADD_FILE procedure has not been called to define the output for a SQL_FILE job
  - A TABLESPACE_DATAFILE parameter has not been defined for a Transportable Import job
  - A TABLESPACE_EXPR metadata filter has not been defined for a Transportable or Tablespace mode Export or Network job
  - The dump file set on an Import or SQL_FILE job was either incomplete or missing a master table specification
- INVALID_OPERATION. Unable to restore master table from a dump file set.
- INTERNAL_ERROR. An inconsistency was detected when the job was started. Additional information may be available through the GET_STATUS procedure.
- SUCCESS_WITH_INFO. The procedure succeeded, but further information is available through the GET_STATUS procedure.
- NO_SUCH_JOB. The specified job does not exist.

Usage Notes

- When this procedure is called to request that the corresponding job be started or restarted, the state of the job is changed from either the Defining or Idling state to the Executing state.
- If the SET_PARALLEL procedure was not called prior to the START_JOB procedure, the initial level of parallelism used in the job will be 1. If SET_PARALLEL was called prior to the job starting, the degree specified by the last SET_PARALLEL call determines the parallelism for the job. On restarts, the parallelism is determined by the previous parallel setting for the job, unless it is overridden by another SET_PARALLEL call.
- To restart a stopped job, an ATTACH function must be performed prior to executing the START_JOB procedure.

54.5.16 STOP_JOB Procedure

This procedure terminates a job, but optionally, preserves the state of the job.

Syntax

```
DBMS_DATAPUMP.STOP_JOB (
   handle      IN NUMBER,
   immediate   IN NUMBER DEFAULT 0,
   keep_master IN NUMBER DEFAULT NULL,
   delay       IN NUMBER DEFAULT 60);
```

Parameters

Table 54-27 STOP_JOB Procedure Parameters

Parameter	Description
handle	The handle of a job. The current session must have previously attached to the handle through a call to either the OPEN or ATTACH function. At the end of the procedure, the user is detached from the handle.
immediate	If nonzero, the worker processes are aborted immediately. This halts the job quickly, but parts of the job will have to be rerun if the job is ever restarted. If zero, the worker processes are allowed to complete their current work item (either metadata or table data) before they are terminated. The job is placed in a Stop Pending state while the workers finish their current work.
keep_master	If nonzero, the master table is retained when the job is stopped. If zero, the master table is dropped when the job is stopped. If the master table is dropped, the job will not be restartable. If the master table is dropped during an export job, the created dump files are deleted.
delay	The number of seconds to wait until other attached sessions are forcibly detached. The delay allows other sessions attached to the job to be notified that a stop has been performed. The job keeps running until either all clients have detached or the delay has been satisfied. If no delay is specified, then the default delay is 60 seconds. If a shorter delay is used, clients might not be able to retrieve the final messages for the job through the GET_STATUS procedure.

Exceptions

- INVALID_HANDLE. The specified handle is not attached to a Data Pump job.
- INVALID STATE. The job is already in the process of being stopped or completed.
- SUCCESS_WITH_INFO. The procedure succeeded, but further information is available through the GET_STATUS procedure.
- NO_SUCH_JOB. The specified job does not exist.

Usage Notes

- This procedure is used to request that the corresponding job stop executing.
- The termination of a job that is in an Executing state may take several minutes to complete in an orderly fashion.
- For jobs in the Defining, Idling, or Completing states, this procedure is functionally equivalent to the DETACH procedure.

- Once a job is stopped, it can be restarted using the ATTACH function and START_JOB procedures, provided the master table and the dump file set are left intact.
- If the KEEP_MASTER parameter is not specified, and the job is in the Defining state or has a mode of Transportable, the master table is dropped. Otherwise, the master table is retained.

54.5.17 WAIT_FOR_JOB Procedure

This procedure runs a job until it either completes normally or stops for some other reason.

Syntax

```
DBMS_DATAPUMP.WAIT_FOR_JOB (
  handle      IN   NUMBER,
  job_state   OUT  VARCHAR2);
```

Parameters

Table 54-28 WAIT_FOR_JOB Procedure Parameters

Parameter	Description
handle	The handle of the job. The current session must have previously attached to the handle through a call to either the OPEN or ATTACH function. At the end of the procedure, the user is detached from the handle.
job_state	The state of the job when it has stopped executing; either STOPPED or COMPLETED.

Exceptions

- SUCCESS_WITH_INFO. The procedure succeeded, but further information is available through the GET_STATUS API.
- INVALID_HANDLE. The job handle is no longer valid.

Usage Notes

This procedure provides the simplest mechanism for waiting for the completion of a Data Pump job. The job should be started before calling WAIT_FOR_JOB. When WAIT_FOR_JOB returns, the job will no longer be executing. If the job completed normally, the final status will be COMPLETED. If the job stopped executing because of a STOP_JOB request or an internal error, the final status will be STOPPED.

55
DBMS_DB_VERSION

The DBMS_DB_VERSION package specifies the Oracle version numbers and other information useful for simple conditional compilation selections based on Oracle versions.

> **See Also:**
>
> *Oracle Database PL/SQL Language Reference* regarding conditional compilation

This package contains the following topics:

- Overview
- Constants
- Examples

55.1 DBMS_DB_VERSION Overview

The DBMS_DB_VERSION package specifies the Oracle version numbers and other information useful for simple conditional compilation selections based on Oracle versions.

The package for the Oracle Database 21c Release 1 version is shown below.

```
PACKAGE DBMS_DB_VERSION IS
   VERSION CONSTANT PLS_INTEGER := 21; -- RDBMS version number
   RELEASE CONSTANT PLS_INTEGER := 1;  -- RDBMS release number
   ver_le_9_1    CONSTANT BOOLEAN := FALSE;
   ver_le_9_2    CONSTANT BOOLEAN := FALSE;
   ver_le_9      CONSTANT BOOLEAN := FALSE;
   ver_le_10_1   CONSTANT BOOLEAN := FALSE;
   ver_le_10_2   CONSTANT BOOLEAN := FALSE;
   ver_le_10     CONSTANT BOOLEAN := FALSE;
   ver_le_11_1   CONSTANT BOOLEAN := FALSE;
   ver_le_11_2   CONSTANT BOOLEAN := FALSE;
   ver_le_11     CONSTANT BOOLEAN := FALSE;
   ver_le_12_1   CONSTANT BOOLEAN := FALSE;
   ver_le_12_2   CONSTANT BOOLEAN := TRUE;
   ver_le_12     CONSTANT BOOLEAN := TRUE;
   ver_le_18     CONSTANT BOOLEAN := TRUE;
END DBMS_DB_VERSION;
```

The boolean constants follow a naming convention. Each constant gives a name for a boolean expression. For example:

- VER_LE_9_1 represents version <= 9 and release <= 1
- VER_LE_10_2 represents version <= 10 and release <= 2
- VER_LE_10 represents version <= 10

A typical usage of these boolean constants is:

```
$IF DBMS_DB_VERSION.VER_LE_10 $THEN
   version 10 and earlier code
$ELSIF DBMS_DB_VERSION.VER_LE_11 $THEN
   version 11 code
$ELSE
   version 12 and later code
$END
```

This code structure will protect any reference to the code for version 12. It also prevents the controlling package constant `DBMS_DB_VERSION.VER_LE_11` from being referenced when the program is compiled under version 10. A similar observation applies to version 11. This scheme works even though the static constant `VER_LE_11` is not defined in version 10 database because conditional compilation protects the `$ELSIF` from evaluation if `DBMS_DB_VERSION.VER_LE_10` is `TRUE`.

55.2 DBMS_DB_VERSION Constants

The `DBMS_DB_VERSION` package contains different constants for different Oracle Database releases.

The Oracle Database 21*c* Release 1 version of the `DBMS_DB_VERSION` package uses the constants shown in the following table.

Table 55-1 DBMS_DB_VERSION Constants

Name	Type	Value	Description
VERSION	PLS_INTEGER	21	Current version
RELEASE	PLS_INTEGER	0	Current release
VER_LE_9	BOOLEAN	FALSE	Version <= 9
VER_LE_9_1	BOOLEAN	FALSE	Version <= 9 and release <= 1
VER_LE_9_2	BOOLEAN	FALSE	Version <= 9 and release <= 2
VER_LE_10	BOOLEAN	FALSE	Version <= 10
VER_LE_10_1	BOOLEAN	FALSE	Version <= 10 and release <= 1
VER_LE_10_2	BOOLEAN	FALSE	Version <=10 and release <= 2
VER_LE_11	BOOLEAN	FALSE	Version <= 11
VER_LE_11_1	BOOLEAN	FALSE	Version <=11 and release <= 1
VER_LE_11_2	BOOLEAN	FALSE	Version <=11 and release <= 2
VER_LE_12	BOOLEAN	FALSE	Version <=12
VER_LE_12_1	BOOLEAN	FALSE	Version <=12 and release <= 1
VER_LE_12_2	BOOLEAN	FALSE	Version <=12 and release <= 2
VER_LE_18	BOOLEAN	FALSE	Version <=18
VER_LE_19	BOOLEAN	FALSE	Version <=19
VER_LE_20	BOOLEAN	FALSE	Version <=20
VER_LE_21	BOOLEAN	TRUE	Version <=21

55.3 DBMS_DB_VERSION Examples

This example uses conditional compilation to guard new features.

```
CREATE OR REPLACE PROCEDURE whetstone IS

 -- Notice that conditional compilation constructs
 -- can interrupt a regular PL/SQL statement.
 -- You can locate a conditional compilation directive anywhere
 -- there is whitespace in the regular statement.

 SUBTYPE my_real IS
    $IF DBMS_DB_VERSION.VER_LE_9 $THEN NUMBER
                                 $ELSE BINARY_DOUBLE
    $END;

 t  CONSTANT my_real := $IF DBMS_DB_VERSION.VER_LE_9 $THEN 0.499975
                                                     $ELSE 0.499975d
                        $END;

 t2 CONSTANT my_real := $if DBMS_DB_VERSION.VER_LE_9 $THEN 2.0
                                                     $ELSE 2.0d
                        $END;

 x  CONSTANT my_real := $IF DBMS_DB_VERSION.VER_LE_9 $THEN 1.0
                                                     $ELSE 1.0d
                        $END;

 y  CONSTANT my_real := $IF DBMS_DB_VERSION.VER_LE_9 $THEN 1.0
                                                     $ELSE 1.0d
                        $END;

 z  MY_REAL;

 PROCEDURE P(x IN my_real, y IN my_real, z OUT NOCOPY my_real) IS
   x1 my_real;
   y1 my_real;
 BEGIN
   x1 := x;
   y1 := y;
   x1 := t * (x1 + y1);
   y1 := t * (x1 + y1);
   z := (x1 + y1)/t2;
 END P;
BEGIN
 P(x, y, z);
 DBMS_OUTPUT.PUT_LINE ('z = '|| z);
END whetstone;
/
```

56
DBMS_DBCOMP

The DBMS_DBCOMP package performs block comparison to detect lost writes or database inconsistencies between a primary database and one or more physical standby databases. It contains one procedure, DBCOMP, which can be executed at any time. (It does not require that the DB_LOST_WRITE_PROTECT initialization parameter be enabled.)

This chapter contains the following sections:

- Using DBMS_DBCOMP
- DBMS_DBCOMP Security Model
- DBCOMP Procedure

Related Topics

- *Oracle Data Guard Concepts and Administration*

56.1 Using DBMS_DBCOMP

The DBMS_DBCOMP.DBCOMP procedure assumes that there is one primary database and one or more physical standby databases. The databases should be at least mounted before block comparison.

> **Note:**
>
> Logical standby databases, far sync instances, and cascaded standbys cannot be the target database for the DBMS_DBCOMP.DBCOMP procedure.

While this procedure is running, you can monitor progress of the compare operation by querying the V$SESSION_LONGOPS view. For example:

```
SQL> SELECT target_desc, sofar, totalwork FROM V$SESSION_LONGOPS WHERE
opname = 'BlockCompare';
```

The output might look as follows:

```
TARGET_DESC                    SO FAR     TOTALWORK
------------------------------ ---------  ----------
Compared Blocks                23914      340639
Lost Writes                    0          0
```

The results can be interpreted as follows:

- The Compared Blocks value is the number of blocks that were scanned (including those that did not use compare callback functions). The number is the sum of all slaves (that is, each slave is responsible for a connection between primary and standby). For example, if

there are two slaves and each slave has compared 1000 blocks, then the value of SOFAR should be 2000.

- The Lost Writes value is the number of lost writes found at both the primary and the standby. Also, it is the sum of all slaves. For Lost Writes, the value of SOFAR should be always equal to the value of TOTALWORK.
- The value of SOFAR should be always less than or equal to the value of TOTALWORK.
- When the block compare slave processes finish, the value of SOFAR should be equal to the value of TOTALWORK.

56.2 DBMS_DBCOMP Security Model

The DBMS_DBCOMP package runs with invoker's rights and requires the SYSDBA or SYSDG or SYSBACKUP privilege.

56.3 Summary of the DBMS_DBCOMP Subprogram

The DBMS_DBCOMP package contains one procedure, DBCOMP.

Subprogram	Description
DBCOMP procedure	The DBMS_DBCOMP.DBCOMP procedure performs block comparison to detect lost writes or database inconsistencies between a primary database and one or more physical standby databases. The DBCOMP procedure can be executed on the primary or on the physical standby while the databases are mounted or open.

56.3.1 DBCOMP Procedure

Use DBCOMP procedure to compare blocks on a primary database and one or more physical standby databases.

Syntax

```
DBMS_DBCOMP.DBCOMP (
  datafile IN varchar2,
  outputfile IN varchar2,
  block_dump IN boolean);
```

Parameters

Parameter	Description
datafile	This can be a data file name or a data file number. Specify 'ALL' to compare all data files.

Parameter	Description
outputfile	This value is used as a prefix in the name of the output file. By default, output files are placed in the dbs/ directory, but the output file argument can contain a relative directory path or an absolute directory path. See Usage Notes for descriptions of the information contained in the output file.
block_dump	This is a Boolean parameter to specify whether block content should be dumped into output files if a pair of blocks of primary and standby databases is not identical. This parameter does not guarantee that all different block pairs are dumped. The default value is FALSE.

Usage Notes

- The output file contains the following columns:
  - **ID**: The block type. For instance, type 02 is undo block type, and 06 is KTB-managed data block type.
  - **TOTAL**: The total number of blocks in the specific block type.
  - **CORR**: The number of corrupted blocks.
  - **SKIPPED**: The number of block pairs that are skipped (ignored) without comparison, such as direct loaded blocks, RMAN optimized blocks, and flashback optimized blocks
  - **DIFFV**: The number of blocks that have different version numbers between primary and standby.
  - **SAMEV**: The number of block pairs that have the same version number between primary and standby.
  - **SAMEV&C**: The number of block pairs that have the same version and the same checksum.
  - **ENCERR**: The number of block pairs that have encryption related errors (usually because the Wallet is not open).
  - **LWLOC**: The number of lost writes on the local database.
  - **LWRMT**: The number of lost writes on the remote databases.
  - **DIFFPAIR** : The number of block pairs that have the same version but different checksum, and which the block compare callback function has concluded are different.

Example 56-1 Example

The following is an example of using the DBMS_DBCOMP.DBCOMP procedure.

```
declare
  Datafile_Name_or_Number varchar2(1000);
  Output_File varchar2(1000);
begin
  dbms_output.enable(1000000);
```

```
  Datafile_Name_or_Number:= 'all' ;
  Output_File:='BlockCompareAll_';
  sys.dbms_dbcomp.DBCOMP(Datafile_Name_or_Number, Output_File, true);
end;
```

57
DBMS_DBFS_CONTENT

The DBMS_DBFS_CONTENT package provides an interface comprising a file system-like abstraction backed by one or more Store Providers.

This chapter contains the following topics:

- Overview
- Security Model
- Constants
- Exceptions
- Operational Notes
- Data Structures
- Summary of DBMS_DBFS_CONTENT Subprograms

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide*

57.1 DBMS_DBFS_CONTENT Overview

The DBMS_DBFS_CONTENT package provides an interface that connects the Oracle database to the DBFS client-side.

In the server, the DBMS_DBFS_CONTENT package is backed by the DBMS_DBFS_CONTENT_SPI package, which includes descriptions but not actual implementations of DBFS stores.

> **See Also:**
>
> - Oracle Database SecureFiles and Large Objects Developer's Guide for a description of DBMS_DBFS_CONTENT and the DBFS architecture
> - Oracle Database SecureFiles and Large Objects Developer's Guide for conceptual information about the DBMS_DBFS_CONTENT package

57.2 DBMS_DBFS_CONTENT Security Model

The DBMS_DBFS_CONTENT package runs under AUTHID CURRENT_USER.

57.3 DBMS_DBFS_CONTENT Constants

The DBMS_DBFS_CONTENT package uses various types of constants.

These are shown in the following tables:

- Table 57-1
- Table 57-2
- Table 57-3
- Table 57-4
- Table 57-5
- Table 57-6
- Table 57-7
- Table 57-8
- Table 57-9
- Table 57-10

Path Name Constants and Types

The following constants are useful for declaring paths and item names. Paths are limited to 1024 characters and item names are limited to 256 characters.

Table 57-1 DBMS_DBFS_CONTENT Constants - Path Names

Constant	Type	Value	Description
NAME_MAX	PLS_INTEGER	256	Maximum length of an absolute path name visible to clients
NAME_T	VARCHAR2(256)	NAME_MAX	Portable alias for string that can represent component names
PATH_MAX	PLS_INTEGER	1024	Maximum length of any individual component of an absolute path name visible to clients
PATH_T	VARCHAR2(1024)	PATH_MAX	Portable alias for string that can represent path names

ContentID Constants

Stores may expose to the user a unique identifier that represents a particular path item in the store. These identifiers are limited to 128 characters.

Table 57-2 DBMS_DBFS_CONTENT Constants - ContentID

Constant	Type	Value	Description
CONTENT_ID_MAX	PLS_INTEGER	128	Maximum length of a store-specific provider-generated contentID that identifies a file-type content item
CONTENT_ID_T	RAW(128)	CONTENT_ID_MAX	Portable alias for raw buffers that can represent contentID values

Path Properties Constants

Every path name in a store is associated with a set of properties. Each property is identified by a string "name", has a string "value" (which might be NULL if unset or undefined or unsupported by a specific store implementation) and a value "typecode" (a numeric discriminant for the actual type of value held in the "value" string.)

Table 57-3 DBMS_DBFS_CONTENT Constants - Properties

Constant	Type	Value	Description
PROPNAME_MAX	PLS_INTEGER	32	Maximum length of a property name
PROPNAME_T	VARCHAR2(32)	PROPNAME_MAX	Portable alias for string that can represent property names
PROPVAL_MAX	PLS_INTEGER	1024	Maximum length of the string value of a property
PROPVAL_T	VARCHAR2(1024)	PATH_MAX	Portable alias for string that can represent property values

Path Name Type Constants

Path items in a store have a item type associated with them. These types represent the kind of entry the item represents in the store.

Table 57-4 DBMS_DBFS_CONTENT Constants - Path Name Types

Constant	Type	Value	Description
TYPE_FILE	PLS_INTEGER	1	A regular file storing content (a logically linear sequence of bytes accessed as a BLOB
TYPE_DIRECTORY	PLS_INTEGER	2	A container of other path name types, including file types

Table 57-4 (Cont.) DBMS_DBFS_CONTENT Constants - Path Name Types

Constant	Type	Value	Description
TYPE_LINK	PLS_INTEGER	3	A symbolic link (that is, an uninterpreted string value associated with a path name). Since symbolic links may represent path names that fall outside the scope of any given store (or even the entire aggregation of stores managed by the DBMS_DBFS_CONTENT interface), or may not even represent path names, clients must be careful in creating symbolic links, and stores must be careful in trying to resolve these links internally.
TYPE_REFERENCE	PLS_INTEGER	4	A hard link which is always a valid path name alias to content
TYPE_SOCKET	PLS_INTEGER	5	UNIX domain socket created using socket interface defined as in socket.h with domain defined as AF_UNIX or AF_LOCAL.

Store Feature Constants

The DBFS content API allows different store providers (and different stores) to describe themselves through a *feature set* (a bitmask indicating which features they support and which ones they do not).

Table 57-5 DBMS_DBFS_CONTENT Constants - Store Features

Constant	Type	Value	Description
FEATURE_FOLDERS	PLS_INTEGER	1	Set if the store supports folders (or directories) as part of hierarchical path names
FEATURE_FOIAT	PLS_INTEGER	2	Set if implicit folder operations within the store (performed as part of a client-requested operation) runs inside autonomous transactions.In general, the use of autonomous transactions is a compromise between (a) simplicity in the implementation and client-controlled transaction scope for all operations, at the cost of greatly reduced concurrency (FEATURE_FOIAT not set), versus (b) more complex implementation and smaller client-controlled transaction scope, at the benefit of greatly increased concurrency (FEATURE_FOIAT set).

Table 57-5 (Cont.) DBMS_DBFS_CONTENT Constants - Store Features

Constant	Type	Value	Description
FEATURE_NOWAIT	PLS_INTEGER	4	Set if the store allows nowait gets of path elements. The default behavior is to wait for row locks; if nowait gets are implemented, the get operation raises an ORA-54 exception if the path element is already locked by another transaction.
FEATURE_ACLS	PLS_INTEGER	8	Set if the store supports Access Control Lists (ACLs) and internal authorization or checking based on these ACLs. ACLs are standard properties but a store may do nothing more than store and retrieve the ACLs without interpreting them in any way.
FEATURE_LINKS	PLS_INTEGER	16	Set if the store supports symbolic links, and if certain types of symbolic links (specifically non-absolute path names) can be internally resolved by the store itself
FEATURE_LINK_DEREF	PLS_INTEGER	32	Set if the store supports symbolic links, and if certain types of symbolic links (specifically non-absolute path names) can be internally resolved by the store itself
FEATURE_REFERENCES	PLS_INTEGER	64	Set if the store supports hard links
FEATURE_LOCKING	PLS_INTEGER	128	Set if the store supports user-level locks (read-only, write-only, read-write) that can be applied on various items of the store, and if the store uses these lock settings to control various types of access to the locked items. User-level locks are orthogonal to transaction locks and persist beyond the scope of any specific transaction, session, or connection — this implies that the store itself may not be able to clean up after dangling locks, and client-applications need to perform any garbage collection.
FEATURE_LOCK_HIERARCHY	PLS_INTEGER	256	Set if the store allows a user-lock to control access to the entire sub-tree under the locked path name.
FEATURE_LOCK_CONVERT	PLS_INTEGER	512	Set if the store supports upgrade or downgrade of locks from one mode to another

Table 57-5 (Cont.) DBMS_DBFS_CONTENT Constants - Store Features

Constant	Type	Value	Description
FEATURE_VERSIONING	PLS_INTEGER	1024	Set if the store supports at least a linear versioning and version management. Different versions of the same path name are identified by monotonic version numbers, with a version-nonqualified path name representing the latest version.
FEATURE_VERSION_PATH	PLS_INTEGER	2048	Set if the store supports a hierarchical namespace for different versions of a path name
FEATURE_SOFT_DELETES	PLS_INTEGER	4096	Set if the store supports a "soft-delete", that is, the ability to delete a path name and make it invisible to normal operations, but retain the ability to restore the path name later (as long as it has not been overwritten by a new create operation). The store also supports purging soft-deleted path names (making them truly deleted), and navigation modes that show soft-deleted items.
FEATURE_HASHING	PLS_INTEGER	8192	Set if the store automatically computes and maintains some type of a secure hash of the contents of a path name (typically a TYPE_FILE path).
FEATURE_HASH_LOOKUP	PLS_INTEGER	16384	Set if the store allows "content-based addressing", that is, the ability to locate a content item based, not on its path name, but on its content hash.

Table 57-5 (Cont.) DBMS_DBFS_CONTENT Constants - Store Features

Constant	Type	Value	Description

FEATURE_FILTERING	PLS_INTEGER	32768	Set if the store allows clients to pass a filter function (a PL/SQL function conforming to the signature below) that returns a logical boolean indicating if a given store item satisfies a selection predicate. Stores that support filtering may be able to more efficiently perform item listing, directory navigation, and deletions by embedding the filtering logic inside their implementation. If filtering is not supported, clients can retrieve more items than necessary and perform the filtering checks themselves, albeit less efficiently.
			A filter predicate is a function with the following signature:
			`function filterFunction(`
			` path IN VARCHAR2,`
			` store_name IN VARCHAR2,`
			` opcode IN INTEGER,`
			` item_type IN INTEGER,`
			` properties IN DBMS_DBFS_CONTENT_PROPERTIES_T,`
			` content IN BLOB)`
			`  RETURN INTEGER;`
			Any PL/SQL function conforming to this signature can examine the contents and properties of a store item, and determine if the item satisfies the selection criterion for the current operation. Any nonzero return value results in the DBMS_DBFS_CONTENT interface processing the item as part of the current operation; a return value that is zero or NULL results in the item being skipped from processing.

FEATURE_SEARCHING	PLS_INTEGER	65536	Set if the store allows clients to pass a text-search filter query to locate type_file path names based on their content. Stores that support searching may use indexes to accelerate such searches; otherwise, clients need to build their own indexes, or else search a potentially larger set of items to locate the ones of interest for the current search.
FEATURE_ASOF	PLS_INTEGER	131072	Set if the store allows clients to use a flashback timestamp in query operations (non-mutating GETPATH Procedures and LIST Function).

Table 57-5 (Cont.) DBMS_DBFS_CONTENT Constants - Store Features

Constant	Type	Value	Description
FEATURE_PROVIDER_PROPS	PLS_INTEGER	262144	Set if the store allows per-operation properties (that control the behavior of the store with regard to the current operation, as opposed to properties associated with individual items).
FEATURE_SNAPSHOTS	PLS_INTEGER	524288	Set if the store allows the use of named, read-only snapshots of its contents. It is up to the provider to implement snapshots using any suitable means (including creating immediate copies of the content, or using copy-on-write) and managing dependencies between snapshots and its parent content view.
FEATURE_CLONES	PLS_INTEGER	1048576	Set if the store allows the use of named, writable clones of its contents. It is up to the provider to implement clones using any suitable means (including creating immediate copies of the content, or using copy-on-write) and managing dependencies between clones and its parent content view.
FEATURE_LOCATOR	PLS_INTEGER	2097152	Set if the store allows direct access to file contents through a LOB locator. Stores that internally manipulate the file contents, perhaps by shredding or reassembling them in separate pieces, performing other transformations, and so on, cannot transparently give out a LOB locator to clients. The file contents of these stores should be accessed using the buffer-based interfaces.
FEATURE_CONTENT_ID	PLS_INTEGER	4194304	Set if the store allows a "pathless", contentID-based access to files (there is no notion of a directory, link, or reference in this model)
FEATURE_LAZY_PATH	PLS_INTEGER	8388608	Set if the store allows a lazy binding of a path name to file content elements that are otherwise identified by a contentID; this feature makes sense only in conjunction with FEATURE_CONTENT_ID

Lock Type Constants

Stores that support locking should implement 3 types of locks: LOCK_READ_ONLY, LOCK_WRITE_ONLY, and LOCK_READ_WRITE.

Table 57-6 DBMS_DBFS_CONTENT Constants - Lock Types

Constant	Type	Value	Description
LOCK_READ_ONLY	PLS_INTEGER	1	Locks as read-only
LOCK_WRITE_ONLY	PLS_INTEGER	2	Locks as write-only
LOCK_READ_WRITE	PLS_INTEGER	3	Locks as read-write

Standard Property Constants

Standard properties are well-defined, mandatory properties associated with all content path names that all stores should support (in the manner described by the content interface), with some exceptions. For example, a read-only store need not implement a `modification_time` or `creation_time`.

All standard properties informally use the `STD` namespace, which clients and stores should avoid using.

Table 57-7 DBMS_DBFS_CONTENT Constants - Standard Properties

Constant	Type	Value	Description
STD_ACCESS_TIME	VARCHAR2(32)	'std:access_time'	TYPECODE_TIMESTAMP in UTC: The time of last access of a path name's contents
STD_ACL	VARCHAR2(32)	'std:acl'	TYPECODE_VARCHAR2: The access control list (in standard ACL syntax) associated with the path name
STD_CANONICAL_PATH	VARCHAR2(32)	'std:canonical_path'	TYPECODE_VARCHAR2: The canonical store-specific path name of an item.
STD_CHANGE_TIME	VARCHAR2(32)	'std:change_time'	TYPECODE_TIMESTAMP in UTC: The time of last change to the metadata of a path name
STD_CHILDREN	VARCHAR2(32)	'std:children'	TYPECODE_NUMBER: The number of child directories/folders a directory/folder path has (this property should be available in providers that support the FEATURE_FOLDERS feature)
STD_CONTENT_TYPE	VARCHAR2 (32)	'std:content_type'	TYPECODE_NUMBER: The client-supplied mime-type(s) (in standard RFC syntax) describing the (typically type_file) path name. The content type is not necessarily interpreted by the store.
STD_CREATION_TIME	VARCHAR2(32)	'std:creation_time'	TYPECODE_TIMESTAMP in UTC: The time at which the item was created (once set, this value never changes for the lifetime of the path name)
STD_DELETED	VARCHAR2(32)	'std:deleted'	TYPECODE_NUMBER as a BOOLEAN: Set to a nonzero number if the path name has been soft-deleted but not yet purged.

Table 57-7 (Cont.) DBMS_DBFS_CONTENT Constants - Standard Properties

Constant	Type	Value	Description
STD_GUID	VARCHAR2(32)	'std:guid'	TYPECODE_NUMBER: A store-specific unique identifier for a path name. Clients must not depend on the GUID being unique across different stores, but a given (*store-name*, *store-specific-path name*) has a stable and unique GUID for its lifetime.
STD_LENGTH	VARCHAR2(32)	'std:length'	TYPECODE_NUMBER: The length of the content (BLOB) of a TYPE_FILE/ TYPE_REFERENCE path, or the length of the referent of a TYPE_LINK symbolic link. Directories do not have a well-defined length and stores are free to set this property to zero, NULL, or any other value.
STD_MODIFICATION_TIME	VARCHAR2(32)	'std:modification_time'	TYPECODE_TIMESTAMP in UTC: The time of last change to the data associated with a path name. Change to the content of a TYPE_FILE/ TYPE_REFERENCE path, the referent of the TYPE_LINK path, and addition or deletion of immediate children in a TYPE_DIRECTORY path, all constitute data changes.
STD_OWNER	VARCHAR2(32)	'std:owner'	TYPECODE_VARCHAR2: A client-supplied (or implicit) owner name for the path name. The owner name may be used (along with the current "principal") for access checks by stores that support ACLs, locking, or both.
STD_PARENT_GUID	VARCHAR2(32)	'std:parent_guid'	TYPECODE_NUMBER: A store-specific unique identifier for the parent of a path name. Clients must not depend on the GUID being unique across different stores, but a given (*store-name*, *store-specific-path name*) has a stable and unique GUID for its lifetime. STD_PARENT_GUID(path name) == STD_GUID(parent(path name))
STD_REFERENT	VARCHAR2(32)	'std:referent'	TYPECODE_VARCHAR2: The content of the symbolic link of a TYPE_LINK path; NULL otherwise. As mentioned, the STD_REFERENT can be an arbitrary string and must not necessarily be interpreted as path name by clients (or such interpretation should be done with great care).

Optional Property Constants

Optional properties are well-defined properties (not mandatory) associated with all content path names that all stores are free to support (but only in the manner described by the DBFS content API).

All optional properties informally use the `opt:` namespace, which clients and stores should avoid using.

Table 57-8 DBMS_DBFS_CONTENT Constants - Optional Properties

Constant	Type	Value	Description
OPT_HASH_TYPE	VARCHAR2(32)	'opt:hash_type'	TYPECODE_NUMBER: The type of hash provided in the opt_hash_value property; see DBMS_CRYPTO for possible options.
OPT_HASH_VALUE	VARCHAR2(32)	'opt:hash_value'	TYPECODE_NUMBER: The hash value of type OPT_HASH_TYPE describing the content of the path name.
OPT_LOCK_COUNT	VARCHAR2(32)	'opt:lock_count'	TYPECODE_NUMBER: The number of (compatible) locks placed on a path name. If different principals are allowed to place compatible (read) locks on a path, the opt_locker must specify all lockers (with repeats so that lock counts can be correctly maintained).
OPT_LOCK_DATA	VARCHAR2(32)	'opt:lock_data'	TYPECODE_NUMBER: The client-supplied user-data associated with a user-lock, uninterpreted by the store.
OPT_LOCKER	VARCHAR2(32)	'opt:locker'	TYPECODE_NUMBER: One or more implicit or client-specified principals that applied a user-lock on a path name.
OPT_LOCK_STATUS	VARCHAR2(32)	'opt:lock_status'	TYPECODE_NUMBER: One of the LOCK_READ_ONLY, LOCK_WRITE_ONLY, LOCK_READ_WRITE values describing the type of lock currently applied on a path name.
OPT_VERSION	VARCHAR2(32)	'opt:version'	TYPECODE_NUMBER: A sequence number for linear versioning of a path name.
OPT_VERSION_PATH	VARCHAR2(32)	'opt:version_path'	TYPECODE_NUMBER: A version-path name for hierarchical versioning of a path name.
OPT_CONTENT_ID	VARCHAR2(32)	'opt:content_id'	TYPECODE_NUMBER: A provider-generated store-specific unique contentID in the form of a string for a file content element (that may optionally not be associated with a path; see FEATURE_CONTENT_ID and FEATURE_LAZY_PATH).

Property Access Flag Constants

Content interface methods to get or set properties can use combinations of property access flags to fetch properties from different name spaces in a single interface call.

Table 57-9 DBMS_DBFS_CONTENT Constants - Property Access Flags

Constant	Type	Value	Description
PROP_NONE	PLS_INTEGER	0	None: used when the client is not interested in any properties, and is invoking the content access method for other reasons (path name existence or lockability validation, data access, and so on)
PROP_STD	PLS_INTEGER	1	Mandatory: used when the client is interested in the standard properties; all standard properties are retrieved if this flag is specified.
PROP_OPT	PLS_INTEGER	2	Optional: used when the client is interested in the optional properties; all optional properties are retrieved if this flag is specified.
PROP_USR	PLS_INTEGER	3	User-defined: used when the client is interested in the user-defined properties; all user-defined properties are retrieved if this flag is specified.
PROP_ALL	PLS_INTEGER	PROP_STD + PROP_OPT + PROP_USR;	All: an alias for the combination of all standard, optional, and user-defined properties
PROP_DATA	PLS_INTEGER	8	Content: used when the client is interested only in data access, and does not care about properties
PROP_SPC	PLS_INTEGER	16	Specific: used when the client is interested in a mix-and-match of different subsets of various property name spaces; the names of the specific properties to fetch are passed into the content interface method call as arguments, and only these property values are fetched and returned to the client. This is useful in cases where there are a very large number of properties potentially accessible, but the client is interested in only a small number of them (and knows the names of these "interesting" properties beforehand). PROP_SPC is applicable only to the various GETPATH operations. Other operations that specify properties ignore PROP_SPC specifications.

Operation Code Constants

All of the operations in the DBFS content API are represented as abstract opcodes.

Clients can use these opcodes to directly and explicitly by invoking the CHECKACCESS Function to verify if a particular operation can be invoked by a given principal on a particular path name.

Table 57-10 DBMS_DBFS_CONTENT Constants - Operation Codes

Constant	Type	Value	Description
OP_CREATE	PLS_INTEGER	1	Create a path item
OP_CREATEFILE	PLS_INTEGER	OP_CREATE	Create a file
OP_CREATELINK	PLS_INTEGER	OP_CREATE	Create a soft link
OP_CREATEREFERENCE	PLS_INTEGER	OP_CREATE	Create a reference (hard link)
OP_DELETE	PLS_INTEGER	2	Soft-deletion, purge, and restore operations are all represented by OP_DELETE
OP_DELETEFILE	PLS_INTEGER	OP_DELETE	Delete a file
OP_DELETEDIRECTORY	PLS_INTEGER	OP_DELETE	Delete a directory
OP_RESTORE	PLS_INTEGER	OP_DELETE	Restore a soft-deleted path item
OP_PURGE	PLS_INTEGER	OP_DELETE	Purge a soft-deleted path item
OP_READ	PLS_INTEGER	3	Read from a path item
OP_GET	PLS_INTEGER	OP_READ	Get a path item for either read or update operations
OP_WRITE	PLS_INTEGER	4	Write a path item
OP_PUT	PLS_INTEGER	OP_WRITE	Put (write) to a path item
OP_RENAME	PLS_INTEGER	5	Rename a path item
OP_RENAMEFROM	PLS_INTEGER	OP_RENAME	Operations performed on the source of a rename
OP_RENAMETO	PLS_INTEGER	OP_RENAME	Operations performed on the destination of a rename
OP_SETPATH	PLS_INTEGER	OP_RENAME	Set a path item name
OP_LIST	PLS_INTEGER	6	Perform a path listing
OP_SEARCH	PLS_INTEGER	7	Perform a search
OP_LOCK	PLS_INTEGER	8	Lock a path item
OP_UNLOCK	PLS_INTEGER	9	Unlock a path item

Table 57-10 (Cont.) DBMS_DBFS_CONTENT Constants - Operation Codes

Constant	Type	Value	Description
OP_ACL	PLS_INTEGER	10	An implicit operation invoked during an OP_CREATE or OP_PUT that specifies a STD_ACL property; the operation tests to see if the principal is allowed to set or change the ACL of a store item
OP_STORE	PLS_INTEGER	11	A catch-all category for miscellaneous store operations that do not fall under any of the other operational interfaces

57.4 Exceptions

DBFS content API operations can raise any one of these top-level exceptions.

Table 57-11 DBMS_DBFS_CONTENT Exceptions

Exception	Code	Description
PATH_EXISTS	64000	A specified path name already exists
INVALID_PARENT	64001	Parent of a specified path name does not exist
INVALID_PATH	64002	Specified path name does not exist, or is not valid
UNSUPPORTED_OPERATION	64003	An operation unsupported by a store was invoked
INVALID_ARGUMENTS	64004	An operation was invoked with invalid arguments
INVALID_ACCESS	64005	Access control checks failed for the current operation
LOCK_CONFLICT	64006	Current operation failed lock conflict check
INVALID_STORE	64007	An invalid store name was specified
INVALID_MOUNT	64008	An invalid mount point was specified
INVALID_PROVIDER	64009	An invalid provider-package was specified
READONLY_PATH	64010	A mutating operation was invoked on a read-only mount or store

57.5 DBMS_DBFS_CONTENT Operational Notes

This topic lists operational notes for DBMS_DBFS_CONTENT implementation, path names, and other operations.

- Implementation
- Path Names
- Other DBMS_DBFS_CONTENT Operations

Implementation

Since the interconnection of the DBMS_DBFS_CONTENT interface and the provider SPI is a 1-to-many pluggable architecture, the interface uses dynamic SQL to invoke methods in the provider SPI, this can lead to runtime errors.

There are no explicit `INIT` or `FINI` methods to indicate when the `DBMS_DBFS_CONTENT` interface plugs or unplugs a particular provider SPI. Provider SPIs must be willing to auto-initialize themselves at any SPI entry-point.

All operations performed by a store provider are "stateless" in that they are complete operations unto themselves. If state is necessary to be maintained for some reason, then the state must be maintained in data structures such as auxiliary tables that can be queried as needed.

Path Names

All path names used in the provider SPI are store-qualified in pair form (`store_name`, `pathname`) where the path name is rooted within the store namespace.

Stores and their providers that support contentID-based access (see `FEATURE_CONTENT_ID` in Table 57-5) also support a form of addressing that is not based on path names. Content items are identified by an explicit store name, a `NULL` path name, and possibly a contentID specified as a parameter or by way of the `OPT_CONTENT_ID` (see Table 57-8) property.

Not all operations are supported with contentID-based access, and applications should depend only on the simplest create or delete functionality being available.

This table lists other operations and provides links to related discussions.

Other DBMS_DBFS_CONTENT Operations

Table 57-12 Other DBMS_DBFS_CONTENT Operations

Other Operations	See ...
Creation	*Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on creation operations
Deletion	*Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on deletion operations
Get (Retrieve) and Put (Insert)	*Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on Get and Put operations
Rename and Move	*Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on Rename and Move operations
Directory Navigation and Search	*Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on Navigation and Search operations
Locking	*Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on Locking operations
Access Check	*Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on Access Check operations

57.6 DBMS_DBFS_CONTENT Data Structures

The DBMS_DBFS_CONTENT package defines RECORD types and TABLE types.

RECORD Types

- FEATURE_T Record Type
- MOUNT_T Record Type
- PATH_ITEM_T Record Type
- PROP_ITEM_T Record Type
- PROPERTY_T Record Type
- STORE_T Record Type

TABLE Types

- FEATURES_T Table Type
- MOUNTS_T Table Type
- PATH_ITEMS_T Table Type
- PROP_ITEMS_T Table Type
- PROPERTIES_T Table Type
- STORES_T Table Type

Usage Notes

There is an approximate correspondence between DBMS_DBFS_CONTENT_PROPERTY_T and PROPERTY_T — the former is a SQL object type that describes the full property tuple, while the latter is a PL/SQL record type that describes only the property value component.

Likewise, there is an approximate correspondence between DBMS_DBFS_CONTENT_PROPERTIES_T and PROPERTIES_T — the former is a SQL nested table type, while the latter is a PL/SQL hash table type.

Dynamic SQL calling conventions force the use of SQL types, but PL/SQL code may be implemented more conveniently in terms of the hash-table types.

The DBMS_DBFS_CONTENT interface provides convenient utility functions to convert between DBMS_DBFS_CONTENT_PROPERTIES_T and PROPERTIES_T (see propertiesT2H and propertiesH2T).

Clients can query the DBMS_DBFS_CONTENT interface for the list of available stores, determine which store is to handle access to a given path name, and determine the feature set for the store.

57.6.1 DBMS_DBFS_CONTENT FEATURE_T Record Type

This type describes a store mount point and its properties.

Syntax

```
TYPE feature_t IS RECORD (
   feature_name    VARCHAR2(32),
   feature_mask    INTEGER,
   feature_state   VARCHAR2(3));
```

Fields

Table 57-13 MOUNT_T Fields

Field	Description
feature_name	Name of feature
feature_mask	Value used to mask off all other bits other than this feature in the feature value
feature_state	'YES' or 'NO' depending on whether the feature is supported on this store

57.6.2 DBMS_DBFS_CONTENT MOUNT_T Record Type

This type describes a store mount point and its properties.

Syntax

```
TYPE mount_t IS RECORD (
   store_name          VARCHAR2(32),
   store_id            NUMBER,
   provider_name       VARCHAR2(32),
   provider_pkg        VARCHAR2(32),
   provider_id         NUMBER,
   provider_version    VARCHAR2(32),
   store_features      INTEGER,
   store_guid          NUMBER,
   store_mount         NAME_T,
   mount_properties    DBMS_DBFS_CONTENT_PROPERTIES_T);
```

Fields

Table 57-14 MOUNT_T Fields

Field	Description
store_name	Name of store
store_id	ID of store
provider_name	Name of the content store
provider_pkg	PL/SQL package name for the content store
provider_id	Unique identifier for the content store

Table 57-14 (Cont.) MOUNT_T Fields

Field	Description
provider_version	Version number for the content store
respos_features	Features supported by this content store
store_guid	Unique ID for this instance of the store
store_mount	Location at which this store instance is mounted
mount_properties	Properties for this mount point (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)

57.6.3 DBMS_DBFS_CONTENT PATH_ITEM_T Record Type

A PATH_ITEM_T is a tuple describing a (store, mount) qualified path in a store, with all standard and optional properties associated with it.

Syntax

```
TYPE path_item_t IS RECORD (
   store                   NAME_T,
   mount                   NAME_T,
   pathname                PATH_T,
   pathtype                VARCHAR2(32),
   filedata                BLOB,
   std_access_time         TIMESTAMP,
   std_acl                 VARCHAR2(1024),
   std_change_time         TIMESTAMP,
   std_children            NUMBER,
   std_content_type        VARCHAR2(1024),
   std_creation_time       TIMESTAMP,
   std_deleted             INTEGER,
   std_guid                INTEGER,
   std_modification_time   TIMESTAMP,
   std_owner               VARCHAR2(32),
   std_parent_guid         INTEGER,
   std_referent            VARCHAR2(1024),
   opt_hash_type           VARCHAR2(32),
   opt_hash_value          VARCHAR2(128),
   opt_lock_count          INTEGER,
   opt_lock_data           VARCHAR2(128),
   opt_locker              VARCHAR2(128),
   opt_lock_status         INTEGER,
   opt_version             INTEGER,
   opt_version_path        PATH_T,
   opt_content_id          CONTENT_ID_T);
```

Fields

Table 57-15 PATH_ITEM_T Fields

Field	Description
store	Name of store
mount	Location at which instance of store is mounted

Table 57-15 (Cont.) PATH_ITEM_T Fields

Field	Description
pathname	Name of path to item
pathtype	Type of object path (see Table 57-4)
filedata	BLOB locator that can be used to access data in the path item
std_access_time	Time of last access of a pathname's contents
std_acl	Access Control List (in standard ACL syntax)
std_change_time	Time of last change to the metadata of a path name
std_children	Number of child directories or folders a directory or folder path (this property should be available in providers that support the feature_folders feature).
std_content_type	One or more client-supplied mime-types (in standard RFC syntax) describing the path name which is typically of type_file. The content type s not necessarily interpreted by the store.
std_creation_time	Time at which the item was created. Once set, this value remains the same for the lifetime of the path name.
std_deleted	Set to a nonzero number if the path name has been soft-deleted but not yet purged (see Table 57-5)
std_guid	Store-specific unique identifier for a path name. Clients must not depend on the GUID being unique across different stores, but a given *store-name*, *store-specific-pathname* has a stable and unique GUID for its lifetime.
std_modification_time	Time of last change to the data associated with a path name. Changes to the content of a type_file or type_reference path, the referent of the type_link path, and addition or deletion of immediate children in a type_directory path, all constitute data changes.
std_owner	Client-supplied (or implicit) owner name for the path name
std_parent_guid	Store-specific unique identifier for the parent of a path name. Clients must not depend on the GUID being unique across different stores, but a given *store-name*, *store-specific-pathname* has a stable and unique GUID for its lifetime. `std_parent_guid(pathname) == std_guid(parent(pathname))`
std_referent	Content of the symbolic link of a type_link path, otherwise NULL. As mentioned before, the std_referent can be an arbitrary string and must not necessarily be interpreted as pathname by clients (or such interpretation should be done with great care).
opt_hash_type	Type of hash provided in the opt_hash_value property (see DBMS_CRYPTO for possible options)
opt_hash_value	Hash value of type opt_hash_type describing the content of the path name
opt_lock_count	Number of compatible locks placed on a path name. If different principals are allowed to place compatible (read) locks on a path, the opt_locker must specify all lockers with repeats so that lock counts can be correctly maintained.

Table 57-15 (Cont.) PATH_ITEM_T Fields

Field	Description
opt_lock_data	Client-supplied user-data associated with a user-lock, uninterpreted by the store
opt_locker	One or more implicit or client-specified principals that applied a user-lock on a path name
opt_lock_status	One of the lock_read_only, lock_write_only, lock_read_write values describing the type of lock currently applied on a path name
opt_version	Sequence number for linear versioning of a path name
opt_version_path	Version path name for hierarchical versioning of a path name
opt_content_id	Stringified provider-generated store-specific unique contentID for a file element (that may optionally not be associated with a path (see FEATURE_CONTENT_ID and FEATURE_LAZY_PATH in Table 57-5)

57.6.4 DBMS_DBFS_CONTENT PROP_ITEM_T Record Type

A PROP_ITEM_T is a tuple describing a (store, mount) qualified path in a store, with all user-defined properties associated with it, expanded out into individual (name, value, type) tuples.

Syntax

```
TYPE prop_item_t IS RECORD (
   store               NAME_T,
   mount                    NAME_T,
   pathname                 PATH_T,
   property_name            PROPNAME_T,
   property_value           PROPVAL_T,
   property_type            INTEGER);
```

Fields

Table 57-16 PROP_ITEM_T Fields

Field	Description
store	Name of store
mount	Location at which instance of store is mounted
pathname	Name of path to item
property_name	Name of the property
property_value	Value of the property
property_type	PL/SQL typecode for the property value

57.6.5 PROPERTY_T Record Type

This type describes a single (`value`, `typecode`) property value tuple; the property name is implied.

See PROPERTIES_T Table Type for more information.

Syntax

```
TYPE property_t  IS RECORD (
   propvalue    PROPVAL_T,
   typecode     INTEGER);
```

Fields

Table 57-17 PROPERTY_T Fields

Field	Description
`propvalue`	Value of property
`typecode`	Typecode

57.6.6 DBMS_DBFS_CONTENT STORE_T Record Type

This type describes a store registered with and managed by the `DBMS_DBFS_CONTENT` interface.

Syntax

```
TYPE store_t IS RECORD (
   store_name          VARCHAR2(32),
   store_id            NUMBER,
   provider_name       VARCHAR2(32),
   provider_pkg        VARCHAR2(32),
   provider_id         NUMBER,
   provider_version    VARCHAR2(32),
   store_features      INTEGER,
   store_guid          NUMBER);
```

Fields

Table 57-18 STORET_T Fields

Field	Description
`store_name`	Name of store
`store_name`	ID of store
`provider_name`	Name of the content store
`provider_pkg`	PL/SQL package name for the content store
`provider_id`	Unique identifier for the content store
`provider_version`	Version number for the content store
`respos_features`	Features supported by this content store

Table 57-18 (Cont.) STORET_T Fields

Field	Description
store_guid	Unique ID for this instance of the store

57.6.7 DBMS_DBFS_CONTENT FEATURES_T Table Type

A table type of FEATURE_T Record Type.

Syntax

```
TYPE features_t IS TABLE OF feature_t;
```

Related Topics

- DBMS_DBFS_CONTENT FEATURE_T Record Type
  This type describes a store mount point and its properties.

57.6.8 MOUNTS_T Table Type

A table type of MOUNT_T Record Type.

Syntax

```
TYPE mounts_t IS TABLE OF mount_t;
```

Related Topics

- DBMS_DBFS_CONTENT MOUNT_T Record Type
  This type describes a store mount point and its properties.

57.6.9 DBMS_DBFS_CONTENT PATH_ITEMS_T Table Type

A table type of PATH_ITEM_T Record Type

Syntax

```
TYPE path_items_t IS TABLE OF path_item_t;
```

Related Topics

- DBMS_DBFS_CONTENT PATH_ITEM_T Record Type
  A PATH_ITEM_T is a tuple describing a (store, mount) qualified path in a store, with all standard and optional properties associated with it.

57.6.10 DBMS_DBFS_CONTENT PROP_ITEMS_T Table Type

A table type of PATH_ITEM_T Record Type.

Syntax

```
TYPE prop_items_t IS TABLE OF prop_item_t;
```

Related Topics

- DBMS_DBFS_CONTENT PATH_ITEM_T Record Type
  A PATH_ITEM_T is a tuple describing a (store, mount) qualified path in a store, with all standard and optional properties associated with it.

57.6.11 DBMS_DBFS_CONTENT PROPERTIES_T Table Type

This is a name-indexed hash table of property tuples. The implicit hash-table association between the index and the value allows the client to build up the full DBMS_DBFS_CONTENT_PROPERTY_T tuples for a PROPERTIES_T.

Syntax

```
TYPE properties_t IS TABLE OF property_t INDEX BY propname_t;
```

57.6.12 STORES_T Table Type

This type describes a store registered with and managed by the DBMS_DBFS_CONTENT interface.

Syntax

```
TYPE stores_t IS TABLE OF store_t;
```

57.7 Summary of DBMS_DBFS_CONTENT Subprograms

This table lists and describes the subprograms used in the DBMS_DBFS_CONTENT Package.

Table 57-19 DBMS_DBFS_CONTENT Package Subprograms

Subprogram	Description
CHECKACCESS Function	Reports if the user (principal) can perform the specified operation on the given path
CHECKSPI Functions and Procedures	Checks if a user-provided package implements all of the DBMS_DBFS_CONTENT_SPI subprograms with the proper signatures, and reports on the conformance.
CREATEDIRECTORY Procedures	Creates a directory
CREATEFILE Procedures	Creates a file
CREATELINK Procedures	Creates a new reference to the source file system element
CREATEREFERENCE Procedures	Creates a physical link to an already existing file system element
DECODEFEATURES Function	Given a feature bit set integer value, returns a FEATURES_T table of the feature bits as FEATURE_T records
DELETECONTENT Procedure	Deletes the file specified by the given contentID
DELETEDIRECTORY Procedure	Deletes a directory
DELETEFILE Procedure	Deletes a file
FEATURENAME Function	Given a feature bit, returns a VARCHAR2 of that feature's name
FLUSHSTATS Function	Flushes DBMS_DBFS_CONTENT statistics to disk
GETDEFAULTACL Procedure	Returns the ACL parameter of the default context

Table 57-19 (Cont.) DBMS_DBFS_CONTENT Package Subprograms

Subprogram	Description
GETDEFAULTASOF Procedure	Returns the `asof` parameter of the default context
GETTDEFAULTCONTEXT Procedure	Returns the default context
GETDEFAULTOWNER Procedure	Returns the `owner` parameter of the default context
GETDEFAULTPRINCIPAL Procedure	Returns the `principal` parameter of the default context
GETFEATURESBYMOUNT Function	Returns features of a store by mount point
GETFEATURESBYNAME Function	Returns features of a store by store name
GETFEATURESBYPATH Function	Returns features of a store by path
GETPATHBYMOUNTID Function	Returns the full absolute path name
GETPATH Procedures	Returns existing path items (such as files and directories)
GETPATHBYSTOREID Function	If the underlying GUID is found in the underlying store, returns the store-qualified path name
GETPATHNOWAIT Procedures	Implies that the operation is for an update, and, if implemented, allows providers to return an exception (`ORA-00054`) rather than wait for row locks.
GETSTOREBYMOUNT Function	Returns a store by way of its mount point
GETSTOREBYNAME Function	Returns a store by way of its name
GETSTOREBYPATH Function	Returns a store by way of its path
GETSTATS Procedure	Returns information about `DBMS_DBFS_CONTENT` statistics collection
GETTRACE Function	Returns whether or not `DBMS_DBFS_CONTENT` tracing is turned on
GETVERSION Function	Returns the version of the `DBMS_DBFS_CONTENT` interface in a standardized format associated with a store
LIST Function	Lists the path items in the specified path meeting the specified filter and other criteria
LISTALLCONTENT Function	Lists all path items in all mounts
LISTALLPROPERTIES Function	Returns a table of all properties for all path items in all mounts
LISTMOUNTS Function	Lists all available mount points, their backing stores, and the store features
LISTSTORES Function	Lists all available stores and their features
LOCKPATH Procedure	Applies user-level locks to the given valid path name
MOUNTSTORE Procedure	Mounts a previously registered store and binds it to the mount point
NORMALIZEPATH Functions	Converts a store-specific or full-absolute path name into normalized form
PROPANY Functions	Provides constructors that take one of a variety of types and return a PROPERTY_T
PROPERTIESH2T Function	Converts a `PROPERTY_T` hash to a `DBMS_DBFS_CONTENT_PROPERTIES_T` table

Table 57-19 (Cont.) DBMS_DBFS_CONTENT Package Subprograms

Subprogram	Description
PROPERTIEST2H Function	Converts a DBMS_DBFS_CONTENT_PROPERTIES_T table to a PROPERTY_T hash
PROPNUMBER Function	Is a constructor that takes a NUMBER and returns a PROPERTY_T
PROPRAW Function	Is a constructor that takes a RAW and returns a PROPERTY_T
PROPTIMESTAMP Function	Is a constructor that takes a TIMESTAMP and returns a PROPERTY_T
PROPVARCHAR2 Function	Is a constructor that takes a VARCAHR2 and returns a PROPERTY_T
PURGEALL Procedure	Purges all soft-deleted entries matching the path and optional filter criteria
PURGEPATH Procedure	Purges any soft-deleted versions of the given path item
PUTPATH Procedures	Creates a new path item
REGISTERSTORE Procedure	Registers a new store
RENAMEPATH Procedures	Renames or moves a path
RESTOREALL Procedure	Restores all soft-deleted path items meeting the path and filter criteria
RESTOREPATH Procedure	Restores all soft-deleted path items that match the given path and filter criteria
SETDEFAULTACL Procedure	Sets the ACL parameter of the default context
SETDEFAULTASOF Procedure	Sets the "as of" parameter of the default context
SETDEFAULTCONTEXT Procedure	Sets the default context
SETDEFAULTOWNER Procedure	Sets the "owner" parameter of the default context
SETDEFAULTPRINCIPAL Procedure	Sets the "principal" parameter of the default context
SETPATH Procedures	Assigns a path name to a path item represented by contentID
SETSTATS Procedure	Enables and disables statistics collection
SETTRACE Procedure	Sets DBMS_DBFS_CONTENT tracing on or off
SPACEUSAGE Procedure	Queries file system space usage statistics
TRACE Procedure	Returns a CLOB that contains the evaluation results
TRACEENABLED Function	Determines if the current trace "severity" set by the SETTRACE Procedure is at least as high as the given trace level
UNLOCKPATH Procedure	Unlocks path items that were previously locked with the LOCKPATH Procedure
UNMOUNTSTORE Procedure	Unmounts a registered store
UNREGISTERSTORE Procedure	Unregisters a store

57.7.1 CHECKACCESS Function

This function reports if the user (`principal`) can perform the specified operation on the given path. This enables verifying the validity of an operation without attempting to perform the

operation. If CHECKACCESS returns 0, then the subprogram invoked to implement that operation should fail with an error.

Syntax

```
DBMS_DBFS_CONTENT.CHECKACCESS (
   path           IN     VARCHAR2,
   pathtype       IN     INTEGER,
   operation      IN     VARCHAR2,
   principal      IN     VARCHAR2,
   store_name     IN     VARCHAR2  DEFAULT NULL)
  RETURN  BOOLEAN;
```

Parameters

Table 57-20 CHECKACCESS Procedure Parameters

Parameter	Description
path	Name of path to check for access
pathtype	Type of object path represents (see Table 57-4)
operation	Operation to be checked (see Table 57-8)
principal	File system user for whom the access check is made
store_name	Name of store

Usage Notes

Whether or not the user invokes this function, a store that supports access control internally performs these checks to guarantee security.

57.7.2 CHECKSPI Functions and Procedures

Given the name of a putative DBMS_DBFS_CONTENT_SPI conforming package, this function or procedure checks whether the package implements all of the provider subprograms with the proper signatures, and reports on the conformance.

Syntax

```
DBMS_DBFS_CONTENT.CHECKSPI (
   package_name        IN              VARCHAR2)
  RETURN  CLOB;

DBMS_DBFS_CONTENT.CHECKSPI (
   schema_name         IN              VARCHAR2,
   package_name        IN              VARCHAR2)
  return  clob;

DBMS_DBFS_CONTENT.CHECKSPI (
   package_name        IN              VARCHAR2,
   chk                 IN OUT NOCOPY   CLOB);

DBMS_DBFS_CONTENT.CHECKSPI (
   schema_name         in              VARCHAR2,
   package_name        in              VARCHAR2,
   chk                 in out nocopy   CLOB);
```

Parameters

Table 57-21 CHECKSPI Procedure Parameters

Parameter	Description
package_name	Name of package
schema_name	Name of schema
chk	CLOB that contains the evaluation results

Usage Notes

- The functional form returns a cached temporary LOB of session duration with the results of the analysis. The caller is expected to manage the lifetime of this LOB, as needed.
- The procedural form generates the results of the analysis into the chk LOB parameter; if the value passed in is NULL, the results are written to the foreground trace file provided that DBMS_DBFS_CONTENT interface tracing is enabled. If neither tracing is enabled nor a valid LOB passed in, the checker does not provide any useful indication of the analysis (other than raise exceptions if it encounters a serious error).
- If schema_name is NULL, standard name resolution rules (current schema, private synonym, public synonym) are used to try and locate a suitable package to analyze.

57.7.3 CREATEDIRECTORY Procedures

This procedure creates a directory.

Syntax

```
DBMS_DBFS_CONTENT.CREATEDIRECTORY (
   path        IN              VARCHAR2,
   properties  IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   prop_flags  IN              INTEGER     DEFAULT PROP_STD,
   recurse     IN              BOOLEAN     DEFAULT FALSE,
   store_name  IN              VARCHAR2    DEFAULT NULL,
   principal   IN              VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.CREATEDIRECTORY (
   path        IN              VARCHAR2,
   properties  IN OUT NOCOPY   PROPERTIES_T,
   prop_flags  IN              INTEGER     DEFAULT PROP_STD,
   recurse     IN              BOOLEAN     DEFAULT FALSE,
   store_name  IN              VARCHAR2    DEFAULT NULL,
   principal   IN              VARCHAR2    DEFAULT NULL);
```

Parameters

Table 57-22 CREATEDIRECTORY Procedure Parameters

Parameter	Description
path	Name of path to the directory

Table 57-22 (Cont.) CREATEDIRECTORY Procedure Parameters

Parameter	Description
properties	One or more properties and their values to be set, returned, or both, depending on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)
prop_flags	Determines which properties are set, returned, or both. Default is PROP_STD. Specify properties to be returned by setting PROP_SPC (see Table 57-9), and providing an instance of the DBMS_DBFS_CONTENT_PROPERTIES_T Table Type with properties whose values are of interest.
recurse	If 0, do not execute recursively; otherwise, recursively create the directories above the given directory
store_name	Name of store
principal	File system user for whom the access check is made

57.7.4 CREATEFILE Procedures

This procedure creates a file.

Syntax

```
DBMS_DBFS_CONTENT.CREATEFILE (
   path        IN              VARCHAR2,
   properties  IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   content     IN OUT NOCOPY   BLOB,
   prop_flags  IN              INTEGER     DEFAULT (PROP_STD + PROP_DATA),
   store_name  IN              VARCHAR2    DEFAULT NULL,
   principal   IN              VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.CREATEFILE (
   path        IN              VARCHAR2,
   properties  IN OUT NOCOPY   PROPERTIES_T,
   content     IN OUT NOCOPY   BLOB,
   prop_flags  IN              INTEGER     DEFAULT (PROP_STD + PROP_DATA),
   store_name  IN              VARCHAR2    DEFAULT NULL,
   principal   IN              VARCHAR2    DEFAULT NULL);
```

Parameters

Table 57-23 CREATEFILE Procedure Parameters

Parameter	Description
path	Name of path to the file
properties	One or more properties and their values to be set, returned, or both, depending on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)
content	BLOB holding data with which to populate the file (optional)

Table 57-23 (Cont.) CREATEFILE Procedure Parameters

Parameter	Description
prop_flags	Determines which properties are set, returned, or both. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the DBMS_DBFS_CONTENT_PROPERTIES_T Table Type with properties whose values are of interest.
store_name	Name of store
principal	File system user for whom the access check is made

57.7.5 CREATELINK Procedures

This procedure creates a new link element srcPath with the value of dstPath. The value of dstPath is not validated or interpreted in any way by this procedure. This is analogous to a UNIX file system symbolic link.

Syntax

```
DBMS_DBFS_CONTENT.CREATELINK (
   srcPath     IN              VARCHAR2,
   dstPath     IN              VARCHAR2,
   properties  IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   prop_flags  IN              INTEGER     DEFAULT PROP_STD,
   store_name  IN              VARCHAR2    DEFAULT NULL,
   principal   IN              VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.CREATELINK (
   srcPath     IN              VARCHAR2,
   dstPath     IN              VARCHAR2,
   properties  IN OUT NOCOPY   PROPERTIES_T,
   prop_flags  IN              INTEGER     DEFAULT PROP_STD,
   store_name  IN              VARCHAR2    DEFAULT NULL,
   principal   IN              VARCHAR2    DEFAULT NULL);
```

Parameters

Table 57-24 CREATELINK Procedure Parameters

Parameter	Description
srcPath	File system entry to create.
dstPath	Value to associate with srcPath.
properties	One or more properties and their values to be set, returned depending, or both, on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)
prop_flags	Determines which properties are set, returned, or both. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the DBMS_DBFS_CONTENT_PROPERTIES_T Table Type with properties whose values are of interest.
store_name	Name of store

Table 57-24 (Cont.) CREATELINK Procedure Parameters

Parameter	Description
principal	File system user for whom the access check is made

57.7.6 CREATEREFERENCE Procedures

This procedure creates a physical link, srcPath, to an already existing file system element, dstPath (such as file or directory). The resulting entry shares the same metadata structures as the value of the dstPath parameter, and so is similar to incrementing a reference count on the file system element. This is analogous to a UNIX file system hard link.

Syntax

```
DBMS_DBFS_CONTENT.CREATEREFERENCE (
   srcPath     IN              VARCHAR2,
   dstPath     IN              VARCHAR2,
   properties  IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   prop_flags  IN              INTEGER     DEFAULT PROP_STD,
   store_name  IN              VARCHAR2    DEFAULT NULL,
   principal   IN              VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.CREATEREFERENCE (
   srcPath     IN              VARCHAR2,
   dstPath     IN              VARCHAR2,
   properties  IN OUT NOCOPY   PROPERTIES_T,
   prop_flags  IN              INTEGER     DEFAULT PROP_STD,
   store_name  IN              VARCHAR2    DEFAULT NULL,
   principal   IN              VARCHAR2    DEFAULT NULL);
```

Parameters

Table 57-25 CREATEREFERENCE Procedure Parameters

Parameter	Description
srcPath	File system entry to create.
dstPath	Path that is the reference to srcPath.
properties	One or more properties and their values to be set, returned, or both, depending on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)
prop_flags	Determines which properties are set, returned. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the DBMS_DBFS_CONTENT_PROPERTIES_T Table Type with properties whose values are of interest.
store_name	Name of store
principal	File system user for whom the access check is made

57.7.7 DECODEFEATURES Function

Given a feature bit set integer value, this function returns a FEATURES_T table of the feature bits as FEATURE_T records.

Syntax

```
DBMS_DBFS_CONTENT.DECODEFEATURES (
   featureSet          IN      INTEGER)
  RETURN FEATURES_T DETERMINISTIC PIPELINED;
```

Parameters

Table 57-26 DECODEFEATURES Function Parameters

Parameter	Description
featureSet	Feature set

Return Values

FEATURES_T Table Type

57.7.8 DELETECONTENT Procedure

This procedure deletes the file specified by the given contentID.

Syntax

```
DBMS_DBFS_CONTENT.DELETECONTENT (
   store_name     IN     VARCHAR2    DEFAULT NULL,
   contentID      IN     RAW,
   filter         IN     VARCHAR2    DEFAULT NULL,
   soft_delete    IN     BOOLEAN     DEFAULT NULL,
   principal      IN     VARCHAR2    DEFAULT NULL);
```

Parameters

Table 57-27 DELETECONTENT Procedure Parameters

Parameter	Description
store_name	Name of store
contentID	Unique identifier for the file to be deleted
filter	A filter, if any, to be applied
soft_delete	If 0, execute a hard (permanent) delete. For any value other than 0, perform a soft delete (see *Oracle Database SecureFiles and Large Objects Developer's Guide*, Deletion Operations).
principal	File system user for whom the access check is made

57.7.9 DELETEDIRECTORY Procedure

This procedure deletes a directory.

If `recurse` is nonzero, it recursively deletes all elements of the directory. A filter, if supplied, determines which elements of the directory are deleted.

Syntax

```
DBMS_DBFS_CONTENT.DELETEDIRECTORY (
   path           IN     VARCHAR2,
   filter         IN     VARCHAR2    DEFAULT NULL,
   soft_delete    IN     BOOLEAN     DEFAULT NULL,
   recurse        IN     BOOLEAN     DEFAULT FALSE,
   store_name     IN     VARCHAR2    DEFAULT NULL,
   principal      IN     VARCHAR2    DEFAULT NULL);
```

Parameters

Table 57-28 DELETEDIRECTORY Procedure Parameters

Parameter	Description
`path`	Name of path to the directory
`filter`	A filter, if any, to be applied
`soft_delete`	If 0, execute a hard (permanent) delete. For any value other than 0, perform a soft delete see *Oracle Database SecureFiles and Large Objects Developer's Guide*, Deletion Operations.
`recurse`	If 0, do not execute recursively. Otherwise, recursively delete the directories and files below the given directory.
`store_name`	Name of store
`principal`	File system user for whom the access check is made

57.7.10 DELETEFILE Procedure

This procedure deletes the specified file.

Syntax

```
DBMS_DBFS_CONTENT.DELETEFILE (
   path           IN     VARCHAR2,
   filter         IN     VARCHAR2    DEFAULT NULL,
   soft_delete    IN     BOOLEAN     DEFAULT NULL,
   store_name     IN     VARCHAR2    DEFAULT NULL,
   principal      IN     VARCHAR2    DEFAULT NULL);
```

Parameters

Table 57-29 DELETEFILE Procedure Parameters

Parameter	Description
`path`	Name of path to the file

Table 57-29 (Cont.) DELETEFILE Procedure Parameters

Parameter	Description
filter	A filter, if any, to be applied
soft_delete	If 0, execute a hard (permanent) delete. For any value other than 0, perform a soft delete (see *Oracle Database SecureFiles and Large Objects Developer's Guide*, Deletion Operations).
store_name	Name of store
principal	File system user for whom the access check is made

57.7.11 FEATURENAME Function

Given a feature bit, this function returns a VARCHAR2 of that feature's name.

Syntax

```
DBMS_DBFS_CONTENT.FEATURENAME (
   featureBit          IN      INTEGER)
  RETURN VARCHAR2 DETERMINISTIC;
```

Parameters

Table 57-30 FEATURENAME Function Parameters

Parameter	Description
featureBit	Bit representation of the feature (see Table 57-5)

Return Values

Name of the feature

57.7.12 FLUSHSTATS Function

This procedure flushes DBMS_DBFS_CONTENT statistics to disk.

Syntax

```
DBMS_DBFS_CONTENT.FLUSHSTATS;
```

57.7.13 GETDEFAULTACL Procedure

This procedure returns the ACL parameter of the default context. This information can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

Syntax

```
DBMS_DBFS_CONTENT.GETDEFAULTACL (
   acl    OUT NOCOPY     VARCHAR2);
```

Parameters

Table 57-31 GETDEFAULTACL Procedure Parameters

Parameter	Description
acl	ACL for all new elements created (implicitly or explicitly) by the current operation

57.7.14 GETDEFAULTASOF Procedure

This procedure returns the "as of" parameter of the default context. This information can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

Syntax

```
DBMS_DBFS_CONTENT.GETDEFAULTASOF (
  asof    OUT NOCOPY     TIMESTAMP);
```

Parameters

Table 57-32 GETDEFAULTASOF Procedure Parameters

Parameter	Description
asof	The "as of" timestamp at which the underlying read-only operation (or its read-only sub-components) executes

57.7.15 GETDEFAULTCONTEXT Procedure

This procedure returns the default context. The information contained in the context can be inserted explicitly by way of arguments to the various method calls, allowing for fine-grained control over individual operations.

Syntax

```
DBMS_DBFS_CONTENT.GETDEFAULTCONTEXT (
   principal    OUT NOCOPY     VARCHAR2,
   owner        OUT NOCOPY     VARCHAR2,
   acl          OUT NOCOPY     VARCHAR2,
   asof         OUT NOCOPY     TIMESTAMP);
```

Parameters

Table 57-33 GETDEFAULTCONTEXT Procedure Parameters

Parameter	Description
principal	Agent (principal) invoking the current operation
owner	Owner for new elements created (implicitly or explicitly) by the current operation

Table 57-33 (Cont.) GETDEFAULTCONTEXT Procedure Parameters

Parameter	Description
acl	ACL for all new elements created (implicitly or explicitly) by the current operation
asof	The "as of" timestamp at which the underlying read-only operation (or its read-only sub-components) executes

57.7.16 GETDEFAULTOWNER Procedure

This procedure returns the "owner" parameter of the default context. This information can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

Syntax

```
DBMS_DBFS_CONTENT.GETDEFAULTOWNER (
   principal    IN     VARCHAR2);
```

Parameters

Table 57-34 GETDEFAULTOWNER Procedure Parameters

Parameter	Description
owner	Owner for new elements created (implicitly or explicitly) by the current operation

57.7.17 GETDEFAULTPRINCIPAL Procedure

This procedure returns the "principal" parameter of the default context. This information contained can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

Syntax

```
DBMS_DBFS_CONTENT.GETDEFAULTPRINCIPAL (
   principal    OUT NOCOPY     VARCHAR2);
```

Parameters

Table 57-35 GETDEFAULTPRINCIPAL Procedure Parameters

Parameter	Description
principal	Agent (principal) invoking the current operation

57.7.18 GETFEATURESBYMOUNT Function

This function returns features of a store by mount point.

Syntax

```
DBMS_DBFS_CONTENT.GETFEATURESBYMOUNT (
   store_mount       IN      VARCHAR2)
  RETURN INTEGER;
```

Parameters

Table 57-36 GETFEATURESBYMOUNT Function Parameters

Parameter	Description
store_mount	Mount point

Return Values

A bit mask of supported features (see FEATURES_T Table Type)

57.7.19 GETFEATURESBYNAME Function

This function returns features of a store by store name.

Syntax

```
DBMS_DBFS_CONTENT.GETFEATURESBYNAME (
   store_name       IN      VARCHAR2)
  RETURN INTEGER;
```

Parameters

Table 57-37 GETFEATURESBYNAME Function Parameters

Parameter	Description
store_name	Name of store

Return Values

A bit mask of supported features (see FEATURES_T Table Type)

57.7.20 GETFEATURESBYPATH Function

This function returns features of a store by path.

Syntax

```
DBMS_DBFS_CONTENT.GETFEATURESBYPATH (
   path       IN      PATH_T)
  RETURN INTEGER;
```

Parameters

Table 57-38 GETFEATURESBYPATH Function Parameters

Parameter	Description
path	PATH_T

Return Values

A bit mask of supported features (see FEATURES_T Table Type)

57.7.21 GETPATH Procedures

This procedure returns existing path items (such as files and directories). This includes both data and metadata (properties).

The client can request (using prop_flags) that specific properties be returned. File path names can be read either by specifying a BLOB locator using the prop_data bitmask in prop_flags (see Table 57-9) or by passing one or more RAW buffers.

When forUpdate is 0, this procedure also accepts a valid asof timestamp parameter as part of ctx that can be used by stores to implement "as of" style flashback queries. Mutating versions of the GETPATH Procedures do not support these modes of operation.

Syntax

```
DBMS_DBFS_CONTENT.GETPATH (
        path        IN              VARCHAR2,
        properties  IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
        content     OUT    NOCOPY   BLOB,
        item_type   OUT             INTEGER,
        prop_flags  IN              INTEGER     DEFAULT (PROP_STD +
                                                         PROP_OPT +
                                                         PROP_DATA),
        asof        IN              TIMESTAMP   DEFAULT NULL,
        forUpdate   IN              BOOLEAN     DEFAULT FALSE,
        deref       IN              BOOLEAN     DEFAULT FALSE,
        store_name  IN              VARCHAR2    DEFAULT NULL,
        principal   IN              VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.GETPATH (
        path        IN              VARCHAR2,
        properties  IN OUT NOCOPY   PROPERTIES_T,
        content     OUT    NOCOPY   BLOB,
        item_type   OUT             INTEGER,
        prop_flags  IN              INTEGER     DEFAULT (PROP_STD +
                                                         PROP_OPT +
                                                         PROP_DATA),
        asof        IN              TIMESTAMP   DEFAULT NULL,
        forUpdate   IN              BOOLEAN     DEFAULT FALSE,
        deref       IN              BOOLEAN     DEFAULT FALSE,
        store_name  IN              VARCHAR2    DEFAULT NULL,
        principal   IN              VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.GETPATH (
        path        IN              VARCHAR2,
        properties  IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
```

```
        amount      IN OUT          NUMBER,
        offset      IN              NUMBER,
        buffers     OUT    NOCOPY   RAW,
        prop_flags  IN              INTEGER     DEFAULT (PROP_STD +
                                                         PROP_OPT +
                                                         PROP_DATA),
        asof        IN              TIMESTAMP   DEFAULT NULL,
        store_name  IN              VARCHAR2    DEFAULT NULL,
        principal   IN              VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.GETPATH (
        path        IN              VARCHAR2,
        properties  IN OUT NOCOPY   PROPERTIES_T,
        amount      IN OUT          NUMBER,
        offset      IN              NUMBER,
        buffers     OUT    NOCOPY   RAW,
        prop_flags  IN              INTEGER     DEFAULT (PROP_STD +
                                                         PROP_OPT +
                                                         PROP_DATA),
        asof        IN              TIMESTAMP   DEFAULT NULL,
        store_name  IN              VARCHAR2    DEFAULT NULL,
        principal   IN              VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.GETPATH (
        path        IN              VARCHAR2,
        properties  IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
        amount      IN OUT          NUMBER,
        offset      IN              NUMBER,
        buffers     OUT    NOCOPY   DBMS_DBFS_CONTENT_RAW_T,
        prop_flags  IN              INTEGER     DEFAULT (PROP_STD +
                                                         PROP_OPT +
                                                         PROP_DATA),
        asof        IN              TIMESTAMP   DEFAULT NULL,
        store_name  IN              VARCHAR2    DEFAULT NULL,
        principal   IN              VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.GETPATH (
        path        IN              VARCHAR2,
        properties  IN OUT NOCOPY   PROPERTIES_T,
        amount      IN OUT          NUMBER,
        offset      IN              NUMBER,
        buffers     OUT    NOCOPY   DBMS_DBFS_CONTENT_RAW_T,
        prop_flags  IN              INTEGER     DEFAULT (PROP_STD +
                                                         PROP_OPT +
                                                         PROP_DATA),
        asof        IN              TIMESTAMP   DEFAULT NULL,
        store_name  IN              VARCHAR2    DEFAULT NULL,
        principal   IN              VARCHAR2    DEFAULT NULL);
```

Parameters

Table 57-39 GETPATH Procedure Parameters

Parameter	Description
`path`	Name of path to path items
`properties`	One or more properties and their values to be returned depending on `prop_flags` (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)

Table 57-39 (Cont.) GETPATH Procedure Parameters

Parameter	Description
content	BLOB holding data which populates the file (optional)
item_type	Type of the path item specified (see Table 57-4)
amount	On input, number of bytes to be read. On output, number of bytes read
offset	Byte offset from which to begin reading
buffer	Buffer to which to write
buffers	Buffers to which to write
prop_flags	Determines which properties are set, returned, or both. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the DBMS_DBFS_CONTENT_PROPERTIES_T Table Type with properties whose values are of interest.
asof	The "as of" timestamp at which the underlying read-only operation (or its read-only sub-components) executes
forUpdate	Specifies that a lock should be taken to signify exclusive write access to the path item
deref	If nonzero, attempts to resolve the given path item to actual data provided it is a reference
store_name	Name of store
principal	Agent (principal) invoking the current operation

57.7.22 GETPATHBYMOUNTID Function

If the underlying GUID is found in the underlying store, this function returns the full absolute path name.

Syntax

```
DBMS_DBFS_CONTENT.GETPATHBYMOUNTID (
   store_mount         IN      VARCHAR2,
   guid                IN      INTEGER)
  RETURN VARCHAR2;
```

Parameters

Table 57-40 GETPATHBYMOUNTID Function Parameters

Parameter	Description
store_mount	Mount point in which the path item with guid resides
guid	Unique ID for the path item

Usage Notes

If the GUID is unknown, a NULL value is returned. Clients are expected to handle this as appropriate.

Return Values

Path of the path item represented by GUID in `store_mount`

57.7.23 GETPATHBYSTOREID Function

If the underlying GUID is found in the underlying store, this function returns the store-qualified path name.

Syntax

```
DBMS_DBFS_CONTENT.GETPATHBYSTOREID (
   store_name          IN      VARCHAR2,
   guid                IN      INTEGER)
  RETURN VARCHAR2;
```

Parameters

Table 57-41 GETPATHBYSTOREID Function Parameters

Parameter	Description
`store_name`	Name of store
`guid`	Unique ID representing the desired path item

Usage Notes

If the GUID is unknown, a `NULL` value is returned. Clients are expected to handle this as appropriate.

Return Values

Store-qualified path name represented by the GUID

57.7.24 GETPATHNOWAIT Procedures

This procedure implies that the operation is for an update, and, if implemented, allows providers to return an exception (`ORA-00054`) rather than wait for row locks.

See `FEATURE_NOWAIT` in Table 57-5 for more information.

Syntax

```
DBMS_DBFS_CONTENT.GETPATHNOWAIT (
        path        IN             VARCHAR2,
        properties  IN OUT NOCOPY  DBMS_DBFS_CONTENT_PROPERTIES_T,
        content     OUT    NOCOPY  BLOB,
        item_type   OUT            INTEGER,
        prop_flags  IN             INTEGER     DEFAULT (PROP_STD +
                                                        PROP_OPT +
                                                        PROP_DATA),
        deref       IN             BOOLEAN     DEFAULT FALSE,
        store_name  IN             VARCHAR2    DEFAULT NULL,
        principal   IN             VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.GETPATHNOWAIT (
```

```
path        IN             VARCHAR2,
properties  IN OUT NOCOPY  PROPERTIES_T,
content     OUT    NOCOPY  BLOB,
item_type   OUT            INTEGER,
prop_flags  IN             INTEGER     DEFAULT (PROP_STD +
                                                PROP_OPT +
                                                PROP_DATA),
deref       IN             BOOLEAN     DEFAULT FALSE,
store_name  IN             VARCHAR2    DEFAULT NULL,
principal   IN             VARCHAR2    DEFAULT NULL);
```

Parameters

Table 57-42 GETPATHNOWAIT Procedure Parameters

Parameter	Description
path	Name of path to path items
properties	One or more properties and their values to be returned depending on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)
content	BLOB holding data which populates the file (optional)
item_type	Type of the path item specified (see Table 57-4)
prop_flags	Determines which properties are returned. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the DBMS_DBFS_CONTENT_PROPERTIES_T Table Type with properties whose values are of interest.
asof	The "as of" timestamp at which the underlying read-only operation (or its read-only sub-components) executes
deref	If nonzero, attempts to resolve the given path item to actual data provided it is a reference
store_name	Name of store
principal	Agent (principal) invoking the current operation

57.7.25 GETSTOREBYMOUNT Function

This function returns a store by way of its name.

Syntax

```
DBMS_DBFS_CONTENT.GETSTOREBYMOUNT (
   store_mount       IN      VARCHAR2)
  RETURN STORE_T;
```

Parameters

Table 57-43 GETSTOREBYMOUNT Function Parameters

Parameter	Description
store_mount	Location at which the store instance is mounted

Return Values

STORE_T Record Type

57.7.26 GETSTOREBYNAME Function

This function returns a store by way of its name.

Syntax

```
DBMS_DBFS_CONTENT.GETSTOREBYNAME (
   store_name       IN      VARCHAR2)
  RETURN STORE_T;
```

Parameters

Table 57-44 GETSTOREBYNAME Function Parameters

Parameter	Description
store_name	Name of store

Return Values

STORE_T Record Type

57.7.27 GETSTOREBYPATH Function

This function returns a store by way of its path.

Syntax

```
DBMS_DBFS_CONTENT.GETSTOREBYPATH (
   path       IN      PATH_T)
  RETURN STORE_T;
```

Parameters

Table 57-45 GETSTOREBYPATH Function Parameters

Parameter	Description
path	PATH_T s

Return Values

STORE_T Record Type

57.7.28 GETSTATS Procedure

This procedure returns information about DBMS_DBFS_CONTENT statistics collection.

Syntax

```
DBMS_DBFS_CONTENT.GETSTATS (
   enabled         OUT    BOOLEAN,
   flush_time      OUT    INTEGER,
   flush_count     OUT    INTEGER);
```

Parameters

Table 57-46 GETSTATS Procedure Parameters

Parameter	Description
enabled	Whether statistics collection is enabled
flush_time	How often to flush the statistics to disk in centiseconds
flush_count	Number of operations to allow between statistics flushes

57.7.29 GETTRACE Function

This function returns whether DBMS_DBFS_CONTENT tracing is turned on or not.

Syntax

```
DBMS_DBFS_CONTENT.GETTRACE
  RETURN INTEGER.
```

Return Values

Returns zero if tracing is off, non-zero if tracing is on.

57.7.30 GETVERSION Function

This function marks each version of the DBMS_DBFS_CONTENT interface.

Syntax

```
DBMS_DBFS_CONTENT.GETVERSION (
  RETURN VARCHAR2;
```

Return Values

A string enumerating the version of the DBMS_DBFS_CONTENT interface in standard naming convention: string: *a.b.c* corresponding to *major*, *minor*, and *patch* components.

57.7.31 ISPATHLOCKED Procedure

This procedure checks if any user-level locks are applied on a given path.

Syntax

```
DBMS_DBFS_CONTENT.ISPATHLOCKED (
   path           IN     VARCHAR2,
   who            IN     VARCHAR2,
   lock_type      IN OUT INTEGER,
   store_name     IN     VARCHAR2    DEFAULT NULL,
   principal      IN     VARCHAR2    DEFAULT NULL);
```

Parameters

Table 57-47 ISPATHLOCKED Procedure Parameters

Parameter	Description
path	Name of path to file items
who	Transaction identifier that has locked the path
lock_type	One of the available lock types (see Table 57-6)
store_name	Name of store
principal	Agent (principal) invoking the current operation

57.7.32 LIST Function

This function lists the path items in the specified path meeting the specified filter and other criteria.

Syntax

```
DBMS_DBFS_CONTENT.LIST (
   path           IN     VARCHAR2,
   filter         IN     VARCHAR2    DEFAULT NULL,
   recurse        IN     INTEGER     DEFAULT 0,
   asof           IN     TIMESTAMP   DEFAULT NULL,
   store_name     IN     VARCHAR2    DEFAULT NULL,
   principal      IN     VARCHAR2    DEFAULT NULL)
  RETURN  DBMS_DBFS_CONTENT_LIST_ITEMS_T PIPELINED;
```

Parameters

Table 57-48 LIST Function Parameters

Parameter	Description
path	Name of path to directories
filter	A filter, if any, to be applied
recurse	If 0, do not execute recursively. Otherwise, recursively list the contents of directories and files below the given directory.

Table 57-48 (Cont.) LIST Function Parameters

Parameter	Description
asof	The "as of" timestamp at which the underlying read-only operation (or its read-only sub-components) executes
store_name	Name of repository
principal	Agent (principal) invoking the current operation

Return Values

DBMS_DBFS_CONTENT_LIST_ITEMS_T Table Type

57.7.33 LISTALLPROPERTIES Function

This function returns a table of all properties for all path items in all mounts.

Syntax

```
DBMS_DBFS_CONTENT.LISTALLPROPERTIES
  RETURN  PROP_ITEMS_T PIPELINED;
```

Return Values

PROP_ITEMS_T Table Type

57.7.34 LISTALLCONTENT Function

This function lists all path items in all mounts.

Syntax

```
DBMS_DBFS_CONTENT.LISTALLCONTENT
  RETURN  PATH_ITEMS_T PIPELINED;
```

Return Values

PATH_ITEMS_T Table Type

57.7.35 LISTMOUNTS Function

This function lists all available mount points, their backing stores, and the store features.

Syntax

```
DBMS_DBFS_CONTENT.LISTMOUNTS
  RETURN MOUNTS_T PIPELINED;
```

Return Values

MOUNTS_T Table Type

Usage Notes

A single mount results in a single returned row, with its `store_mount` field of the returned records set to `NULL`.

57.7.36 LISTSTORES Function

This function lists all available stores and their features.

Syntax

```
DBMS_DBFS_CONTENT.LISTSTORES
  RETURN STORES_T PIPELINED;
```

Return Values

STORES_T Table Type

Usage Notes

The `store_mount` field of the returned records is set to `NULL` (since mount-points are separate from stores themselves).

57.7.37 LOCKPATH Procedure

This procedure applies user-level locks to the given valid path name (subject to store feature support), and optionally associates user-data with the lock.

Syntax

```
DBMS_DBFS_CONTENT.LOCKPATH (
   path           IN     VARCHAR2,
   who            IN     VARCHAR2,
   lock_type      IN     INTEGER,
   waitForRowLock IN     INTEGER     DEFAULT 1,
   store_name     IN     VARCHAR2    DEFAULT NULL,
   principal      IN     VARCHAR2    DEFAULT NULL);
```

Parameters

Table 57-49 LOCKPATH Procedure Parameters

Parameter	Description
`path`	Name of path to file items
`who`	Transaction identifier that has locked the path
`lock_type`	One of the available lock types (see Table 57-6)
`waitForRowLock`	Determines if a row is locked by a transaction or not
`store_name`	Name of store
`principal`	Agent (principal) invoking the current operation

57.7.38 MOUNTSTORE Procedure

This procedure mounts a previously registered store and binds it to the mount point.

Syntax

```
DBMS_DBFS_CONTENT.MOUNTSTORE (
   store_mount     in      VARCHAR2   DEFAULT NULL,
   singleton       in      BOOLEAN    DEFAULT FALSE,
   principal       in      VARCHAR2   DEFAULT NULL,
   owner           in      VARCHAR2   DEFAULT NULL,
   acl             in      VARCHAR2   DEFAULT NULL,
   asof            in      TIMESTAMP  DEFAULT NULL,
   read_only       in      BOOLEAN    DEFAULT FALSE);
```

Parameters

Table 57-50 MOUNTSTORE Procedure Parameters

Parameter	Description
store_mount	Path name to use to mount this store
singleton	Whether the mount is a single backend store on the system
principal	Agent (principal) invoking the current operation
owner	Owner for new elements created (implicitly or explicitly) by the current operation
acl	ACL for all new elements created (implicitly or explicitly) by the current operation
asof	The "as of" timestamp at which the underlying read-only operation (or its read-only sub-components) executes
read_only	Whether the mount is read-only

Usage Notes

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for information on mounting a registered store

57.7.39 NORMALIZEPATH Functions

This function converts a store-specific or full-absolute path name into normalized form.

It does the following:

- verifies that the path name is absolute, and so starts with "/"
- collapses multiple consecutive "/" into a single "/"
- strips trailing "/"

- breaks up a store-specific normalized path name into 2 components - parent pathname, trailing component name
- breaks up a full-absolute normalized path name into 3 components - store name, parent pathname, trailing component name

Syntax

```
DBMS_DBFS_CONTENT.NORMALIZEPATH (
   path        IN              VARCHAR2,
   parent      OUT NOCOPY      VARCHAR2,
   tpath       OUT NOCOPY      VARCHAR2)
  RETURN VARCHAR2;

DBMS_DBFS_CONTENT.NORMALIZEPATH (
   path        IN              VARCHAR2,
   store_name  OUT NOCOPY      VARCHAR2,
   parent      OUT NOCOPY      VARCHAR2,
   tpath       OUT NOCOPY      VARCHAR2)
  RETURN VARCHAR2;
```

Parameters

Table 57-51 NORMALIZEPATH Function Parameters

Parameter	Description
path	Name of path to file items
store_name	Name of store
parent	Parent path name
tpath	Name of trailing path item

Return Values

The completely normalized store-specific or full-absolute path name

57.7.40 PROPANY Functions

This function provides constructors that take one of a variety of types and return a PROPERTY_T.

Syntax

```
DBMS_DBFS_CONTENT.PROPANY (
   val      IN      NUMBER)
RETURN PROPERTY_T;

DBMS_DBFS_CONTENT.PROPANY (
   val      IN      VARCHAR2)
RETURN PROPERTY_T;

DBMS_DBFS_CONTENT.PROPANY (
   val      IN      TIMESTAMP)
RETURN PROPERTY_T;

DBMS_DBFS_CONTENT.PROPANY (
```

```
   val      IN      RAW)
RETURN PROPERTY_T;
```

Parameters

Table 57-52 PROPANY Function Parameters

Parameter	Description
val	Value

Return Values

PROPERTY_T Record Type

57.7.41 PROPERTIESH2T Function

This function converts a PROPERTY_T hash to a DBMS_DBFS_CONTENT_PROPERTIES_T table.

Syntax

```
DBMS_DBFS_CONTENT.PROPERTIEST2H (
   pprops      IN      PROPERTIES_T)
RETURN DBMS_DBFS_CONTENT_PROPERTIES_T;
```

Parameters

Table 57-53 PROPERTIEST2H Function Parameters

Parameter	Description
sprops	A PROPERTIES_T hash

Return Values

DBMS_DBFS_CONTENT_PROPERTIES_T Table Type

57.7.42 PROPERTIEST2H Function

This function converts a DBMS_DBFS_CONTENT_PROPERTIES_T table to a PROPERTY_T hash.

Syntax

```
DBMS_DBFS_CONTENT.PROPERTIEST2H (
   sprops      IN      DBMS_DBFS_CONTENT_PROPERTIES_T)
RETURN properties_t;
```

Parameters

Table 57-54 PROPERTIEST2H Function Parameters

Parameter	Description
sprops	A DBMS_DBFS_CONTENT_PROPERTIES_T table

Return Values

PROPERTIES_T Table Type

57.7.43 PROPNUMBER Function

This function is a constructor that takes a number and returns a PROPERTY_T.

Syntax

```
DBMS_DBFS_CONTENT.PROPNUMBER (
   val      IN      NUMBER)
RETURN PROPERTY_T;
```

Parameters

Table 57-55 PROPNUMBER Function Parameters

Parameter	Description
val	Value

Return Values

PROPERTY_T Record Type

57.7.44 PROPRAW Function

This function is a constructor that takes a RAW and returns a PROPERTY_T.

Syntax

```
DBMS_DBFS_CONTENT.PROPRAW (
   val      IN      RAW)
RETURN PROPERTY_T;
```

Parameters

Table 57-56 PROPRAW Function Parameters

Parameter	Description
val	Value

Return Values

PROPERTY_T Record Type

57.7.45 PROPTIMESTAMP Function

This function is a constructor that takes a TIMESTAMP and returns a PROPERTY_T.

Syntax

```
DBMS_DBFS_CONTENT.PROPTIMESTAMP (
   val      IN      TIMESTAMP)
RETURN PROPERTY_T;
```

Parameters

Table 57-57 PROPTIMESTAMP Function Parameters

Parameter	Description
val	Value

Return Values

PROPERTY_T Record Type

57.7.46 PROPVARCHAR2 Function

This function is a constructor that takes a VARCHAR2 and returns a PROPERTY_T.

Syntax

```
DBMS_DBFS_CONTENT.PROPVARCHAR2 (
   val      IN      VARCHAR2)
RETURN PROPERTY_T;
```

Parameters

Table 57-58 PROPNUMBER Function Parameters

Parameter	Description
val	Value

Return Values

PROPERTY_T Record Type

57.7.47 PURGEALL Procedure

This procedure purges all soft-deleted entries matching the path and optional filter criteria.

Syntax

```
DBMS_DBFS_CONTENT.PURGEALL (
   path           IN      VARCHAR2,
   filter         IN      VARCHAR2    DEFAULT NULL,
   store_name     IN      VARCHAR2    DEFAULT NULL,
   principal      IN      VARCHAR2    DEFAULT NULL);
```

Parameters

Table 57-59 PURGEALL Procedure Parameters

Parameter	Description
path	Name of path to file items
filter	A filter, if any, to be applied based on specified criteria
store_name	Name of store
principal	Agent (principal) invoking the current operation

57.7.48 PURGEPATH Procedure

This procedure purges any soft-deleted versions of the given path item.

Syntax

```
DBMS_DBFS_CONTENT.PURGEPATH (
   path           IN      VARCHAR2,
   filter         IN      VARCHAR2    DEFAULT NULL,
   store_name     IN      VARCHAR2    DEFAULT NULL,
   principal      IN      VARCHAR2    DEFAULT NULL);
```

Parameters

Table 57-60 PURGEPATH Procedure Parameters

Parameter	Description
path	Name of path to file items
filter	A filter, if any, to be applied
store_name	Name of store
principal	Agent (principal) invoking the current operation

57.7.49 PUTPATH Procedures

This procedure creates a new path item.

Syntax

```
DBMS_DBFS_CONTENT.PUTPATH (
   path        IN              VARCHAR2,
   properties  IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   content     IN OUT NOCOPY   BLOB,
   item_type   OUT             INTEGER,
   prop_flags  IN              INTEGER     DEFAULT (PROP_STD +
                                                    PROP_OPT +
                                                    PROP_DATA),
   store_name  IN              VARCHAR2    DEFAULT NULL,
   principal   IN              VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.PUTPATH (
   path        IN              VARCHAR2,
```

```
   properties  IN OUT NOCOPY   PROPERTIES_T,
   content     IN OUT NOCOPY   BLOB,
   item_type   OUT             INTEGER,
   prop_flags  IN              INTEGER     DEFAULT (PROP_STD +
                                                    PROP_OPT +
                                                    PROP_DATA),
   store_name  IN              VARCHAR2    DEFAULT NULL,
   principal   IN              VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.PUTPATH (
   path        IN              VARCHAR2,
   properties  IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   amount      IN              NUMBER,
   offset      IN              NUMBER,
   buffer      IN              RAW,
   prop_flags  IN              INTEGER     DEFAULT (PROP_STD +
                                                    PROP_OPT),
   store_name  IN              VARCHAR2    DEFAULT NULL,
   principal   IN              VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.PUTPATH (
   path        IN              VARCHAR2,
   properties  IN OUT NOCOPY   PROPERTIES_T,
   amount      IN              NUMBER,
   offset      IN              NUMBER,
   buffer      IN              RAW,
   prop_flags  IN              INTEGER     DEFAULT (PROP_STD +
                                                    PROP_OPT),
   store_name  IN              VARCHAR2    DEFAULT NULL,
   principal   IN              VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.PUTPATH (
   path        IN              VARCHAR2,
   properties  IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   written     OUT             NUMBER,
   offset      IN              NUMBER,
   buffers     IN             DBMS_DBFS_CONTENT_RAW_T,
   prop_flags  IN              INTEGER     DEFAULT (PROP_STD +
                                                    PROP_OPT),
   store_name  IN              VARCHAR2    DEFAULT NULL,
   principal   IN              VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.PUTPATH (
   path        IN              VARCHAR2,
   properties  IN OUT NOCOPY   PROPERTIES_T,
   written     OUT             NUMBER,
   offset      IN              NUMBER,
   buffers     IN              DBMS_DBFS_CONTENT_RAW_T,
   prop_flags  IN              INTEGER     DEFAULT (PROP_STD +
                                                    PROP_OPT),
   store_name  IN              VARCHAR2    DEFAULT NULL,
   principal   IN              VARCHAR2    DEFAULT NULL);
```

Parameters

Table 57-61 PUTPATH Procedure Parameters

Parameter	Description
path	Name of path to file items

Table 57-61 (Cont.) PUTPATH Procedure Parameters

Parameter	Description
properties	One or more properties and their values to be set depending on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)
content	BLOB holding data which populates the file (optional)
item_type	Type of the path item specified (see Table 57-4)
amount	Number of bytes to be read
offset	Byte offset from which to begin reading
buffer	Buffer to which to write
buffers	Buffers to which to write
prop_flags	Determines which properties are set. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the DBMS_DBFS_CONTENT_PROPERTIES_T Table Type with properties whose values are of interest.
store_name	Name of store
principal	Agent (principal) invoking the current operation

57.7.50 REGISTERSTORE Procedure

This procedure registers a new store backed by a provider that uses a store provider (conforming to the DBMS_DBFS_CONTENT_SPI package signature).

This method is to be used primarily by store providers after they have created a new store.

Syntax

```
DBMS_DBFS_CONTENT.REGISTERSTORE (
   store_name          IN      VARCHAR2,
   provider_name       IN      VARCHAR2,
   provider_package    IN      VARCHAR2);
```

Parameters

Table 57-62 REGISTERSTORE Procedure Parameters

Parameter	Description
store_name	Name of store, must be unique
provider_name	Name of provider
provider_package	Store provider

57.7.51 RENAMEPATH Procedures

This procedure renames or moves a path. This operation can be performed across directory hierarchies and mount-points as long as it is within the same store.

> **Note:**
>
> See *Oracle Database SecureFiles and Large Objects Developer's Guide* for Rename and Move operations

Syntax

```
DBMS_DBFS_CONTENT.RENAMEPATH (
   oldPath     IN              VARCHAR2,
   newPath     IN              VARCHAR2,
   properties  IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   store_name  IN              VARCHAR2    DEFAULT NULL,
   principal   IN              VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.RENAMEPATH (
   oldPath     IN              VARCHAR2,
   newPath     IN              VARCHAR2,
   properties  IN OUT NOCOPY   PROPERTIES_T,
   store_name  IN              VARCHAR2    DEFAULT NULL,
   principal   IN              VARCHAR2    DEFAULT NULL);
```

Parameters

Table 57-63 RENAMEPATH Procedure Parameters

Parameter	Description
`oldPath`	Name of path prior to renaming
`newPath`	Name of path after renaming
`properties`	One or more properties and their values to be set depending on `prop_flags` (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)
`store_name`	Name of store, must be unique
`principal`	Agent (principal) invoking the current operation

57.7.52 RESTOREALL Procedure

This procedure restores all soft-deleted path items meeting the path and optional filter criteria.

Syntax

```
DBMS_DBFS_CONTENT.RESTOREALL (
   path           IN      VARCHAR2,
   filter         IN      VARCHAR2    DEFAULT NULL,
```

```
   store_name     IN      VARCHAR2    DEFAULT NULL,
   principal      IN      VARCHAR2    DEFAULT NULL);
```

Parameters

Table 57-64 RESTOREALL Procedure Parameters

Parameter	Description
path	Name of path to file items
filter	A filter, if any, to be applied
store_name	Name of store
principal	Agent (principal) invoking the current operation

57.7.53 RESTOREPATH Procedure

This procedure restores all soft-deleted path items that match the given path and optional filter criteria.

Syntax

```
DBMS_DBFS_CONTENT.RESTOREPATH (
   path           IN      VARCHAR2,
   filter         IN      VARCHAR2    DEFAULT NULL,
   store_name     IN      VARCHAR2    DEFAULT NULL,
   principal      IN      VARCHAR2    DEFAULT NULL);
```

Parameters

Table 57-65 RESTOREPATH Procedure Parameters

Parameter	Description
path	Name of path to file items
filter	A filter, if any, to be applied
store_name	Name of store
principal	Agent (principal) invoking the current operation

57.7.54 SETDEFAULTACL Procedure

This procedure sets the ACL parameter of the default context.

This information can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

Syntax

```
DBMS_DBFS_CONTENT.SETDEFAULTACL (
   acl    IN     VARCHAR2);
```

Parameters

Table 57-66 SETDEFAULTACL Procedure Parameters

Parameter	Description
acl	ACL for all new elements created (implicitly or explicitly) by the current operation

Usage Notes

- NULL by default, this parameter be can be cleared by setting it to NULL.
- The parameters, once set, remain as a default for the duration of the session, and is inherited by all operations for which the default is not explicitly overridden.

57.7.55 SETDEFAULTASOF Procedure

This procedure sets the "as of" parameter of the default context. This information can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

Syntax

```
DBMS_DBFS_CONTENT.SETDEFAULTASOF (
  asof    IN     TIMESTAMP);
```

Parameters

Table 57-67 SETDEFAULTASOF Procedure Parameters

Parameter	Description
asof	The "as of" timestamp at which the underlying read-only operation (or its read-only sub-components) executes

Usage Notes

- NULL by default, this parameter be can be cleared by setting it to NULL.
- The parameters, once set, remain as a default for the duration of the session, and is inherited by all operations for which the default is not explicitly overridden.

57.7.56 SETDEFAULTCONTEXT Procedure

This procedure sets the default context. The information contained in the context can be inserted explicitly by way of arguments to the various method calls, allowing for fine-grained control over individual operations.

Syntax

```
DBMS_DBFS_CONTENT.SETDEFAULTCONTEXT (
   principal    IN     VARCHAR2,
   owner        IN     VARCHAR2,
   acl          IN     VARCHAR2,
   asof         IN     TIMESTAMP);
```

Parameters

Table 57-68 SETDEFAULTCONTEXT Procedure Parameters

Parameter	Description
`principal`	Agent (principal) invoking the current operation
`owner`	Owner for new elements created (implicitly or explicitly) by the current operation
`acl`	ACL for all new elements created (implicitly or explicitly) by the current operation
`asof`	The "as of" timestamp at which the underlying read-only operation (or its read-only sub-components) executes

Usage Notes

- All of the context parameters are `NULL` by default, and be can be cleared by setting them to `NULL`.
- The context parameters, once set, remain as defaults for the duration of the session, and are inherited by all operations for which the defaults are not explicitly overridden.

57.7.57 SETDEFAULTOWNER Procedure

This procedure sets the "owner" parameter of the default context. This information can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

Syntax

```
DBMS_DBFS_CONTENT.SETDEFAULTOWNER (
   principal    IN     VARCHAR2);
```

Parameters

Table 57-69 SETDEFAULTOWNER Procedure Parameters

Parameter	Description
`owner`	Owner for new elements created (implicitly or explicitly) by the current operation

Usage Notes

- `NULL` by default, this parameter be can be cleared by setting it to `NULL`.
- The parameters, once set, remain as a default for the duration of the session, and is inherited by all operations for which the default is not explicitly overridden.

57.7.58 SETDEFAULTPRINCIPAL Procedure

This procedure sets the "principal" parameter of the default context. This information contained can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

Syntax

```
DBMS_DBFS_CONTENT.SETDEFAULTPRINCIPAL (
   principal    IN     VARCHAR2);
```

Parameters

Table 57-70 SETDEFAULTPRINCIPAL Procedure Parameters

Parameter	Description
`principal`	Agent (principal) invoking the current operation

Usage Notes

- `NULL` by default, this parameter be can be cleared by setting it to `NULL`.
- The parameters, once set, remain as a default for the duration of the session, and is inherited by all operations for which the default is not explicitly overridden.

57.7.59 SETPATH Procedures

This procedure assigns a path name to a path item represented by contentID.

Stores and their providers that support contentID-based access and lazy path name binding also support the `SETPATH Procedure` that associates an existing `contentID` with a new path.

> **Note:**
>
> See *Oracle Database SecureFiles and Large Objects Developer's Guide* for Rename and Move operations

Syntax

```
DBMS_DBFS_CONTENT.SETPATH (
   store_name  IN              VARCHAR2,
   contentID   IN              RAW,
   path        IN              VARCHAR2,
   properties  IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   principal   IN              VARCHAR2    DEFAULT NULL);

DBMS_DBFS_CONTENT.SETPATH (
   store_name  IN              VARCHAR2,
   contentID   IN              RAW,
   path        IN              VARCHAR2,
   properties  IN OUT NOCOPY   PROPERTIES_T,
   principal   IN              VARCHAR2    DEFAULT NULL);
```

Parameters

Table 57-71 SETPATH Procedure Parameters

Parameter	Description
store_name	Name of the store
contentID	Unique identifier for the item to be associated
path	Name of path to path item
properties	One or more properties and their values to be set depending on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)
principal	Agent (principal) invoking the current operation

57.7.60 SETSTATS Procedure

This procedure enables and disables statistics collection.

The client can optionally control the flush settings by specifying non-NULL values for the time, count or both parameters.

Syntax

```
DBMS_DBFS_CONTENT.SETSTATS (
   enable          IN    BOOLEAN,
   flush_time      IN    INTEGER,
   flush_count     IN    INTEGER);
```

Parameters

Table 57-72 SETSTATS Procedure Parameters

Parameter	Description
enable	If TRUE, enable statistics collection. If FALSE, disable statistics collection.
flush_time	How often to flush the statistics to disk in centiseconds
flush_count	Number of operations to allow between statistics flushes

Usage Notes

The SETSTATS Procedure buffers statistics in-memory for a maximum of flush_time centiseconds or a maximum of flush_count operations (whichever limit is reached first), or both, at which time the buffers are implicitly flushed to disk.

57.7.61 SETTRACE Procedure

This procedure sets the DBMS_DBFS_CONTENT tracing severity to the given level, 0 being "off".

Syntax

```
DBMS_DBFS_CONTENT.SETTRACE
     trclvl      IN         INTEGER);
```

Parameters

Table 57-73 SETTRACE Procedure Parameters

Parameter	Description
trclvl	Level of the tracing, higher values implying more tracing

57.7.62 SPACEUSAGE Procedure

This procedure queries file system space usage statistics.

Providers are expected to support this subprogram for their stores (and to make a best effort determination of space usage, especially if the store consists of multiple tables, indexes, LOBs, and so on).

Syntax

```
DBMS_DBFS_CONTENT.SPACEUSAGE (
   path          IN        VARCHAR2,
   blksize       OUT       INTEGER,
   tbytes        OUT       INTEGER,
   fbytes        OUT       INTEGER,
   nfile         OUT       INTEGER,
   ndir          OUT       INTEGER,
   nlink         OUT       INTEGER,
   nref          OUT       INTEGER,
   store_name    IN        VARCHAR2 DEFAULT NULL);
```

Parameters

Table 57-74 SPACEUSAGE Procedure Parameters

Parameter	Description
path	Name of path to file items
blksize	Natural tablespace blocksize that holds the store. If multiple tablespaces with different blocksizes are used, any valid blocksize is acceptable.
tbytes	Total size of the store in bytes computed over all segments that comprise the store
fbytes	Free or unused size of the store in bytes computed over all segments that comprise the store
nfile	Number of currently available files in the store

Table 57-74 (Cont.) SPACEUSAGE Procedure Parameters

Parameter	Description
ndir	Number of currently available directories in the store
nlink	Number of currently available links in the store
nref	Number of currently available references in the store
store_name	Name of store

Usage Notes

- A space usage query on the top-level root directory returns a combined summary of the space usage of all available distinct stores under it (if the same store is mounted multiple times, is still counted only once).
- Since database objects are dynamically expandable, it is not easy to estimate the division between "free" space and "used" space.

57.7.63 TRACE Procedure

This procedure outputs tracing to the current foreground trace file.

Syntax

```
DBMS_DBFS_CONTENT.TRACE
   sev         IN              INTEGER,
   msg0        IN              VARCHAR2,
   msg1        IN              VARCHAR     DEFAULT '',
   msg2        IN              VARCHAR     DEFAULT '',
   msg3        IN              VARCHAR     DEFAULT '',
   msg4        IN              VARCHAR     DEFAULT '',
   msg5        IN              VARCHAR     DEFAULT '',
   msg6        IN              VARCHAR     DEFAULT '',
   msg7        IN              VARCHAR     DEFAULT '',
   msg8        IN              VARCHAR     DEFAULT '',
   msg9        IN              VARCHAR     DEFAULT '',
   msg10       IN              VARCHAR     DEFAULT '');
```

Parameters

Table 57-75 TRACE Procedure Parameters

Parameter	Description
sev	Severity at which trace message is output
msg*	One or more message strings to be output. If more than one message is specified, all are output.

Usage Notes

- Trace information is written to the foreground trace file, with varying levels of detail as specified by the trace level arguments.
- The global trace level consists of 2 components: "severity" and "detail". These can be thought of as additive bitmasks.

The "severity" allows the separation of top level as compared to low-level tracing of different components, and allows the amount of tracing to be increased as needed. There are no semantics associated with different levels, and users are free to set trace at any severity they choose, although a good rule of thumb would use severity "1" for top level API entry and exit traces, "2" for internal operations, and "3" or greater for very low-level traces.

The "detail" controls how much additional information: timestamps, short-stack, etc. is dumped along with each trace record.

57.7.64 TRACEENABLED Function

This function determines if the current trace "severity" set by the SETTRACE Procedure is at least as high as the given trace level.

Syntax

```
DBMS_DBFS_CONTENT.TRACEENABLED(
   sev         IN              INTEGER)
  RETURN  INTEGER;
```

Parameters

Table 57-76 TRACEENABLED Procedure Parameters

Parameter	Description
sev	Severity at which trace message is output

Return Values

Returns 0 if the requested severity level is lower than the currently set trace severity level; 1 otherwise.

Related Topics

- SETTRACE Procedure
  This procedure sets the DBMS_DBFS_CONTENT tracing severity to the given level, 0 being "off".

57.7.65 UNLOCKPATH Procedure

This procedure unlocks path items that were previously locked with the LOCKPATH Procedure.

Syntax

```
DBMS_DBFS_CONTENT.UNLOCKPATH (
   path           IN     VARCHAR2,
   who            IN     VARCHAR2,
   waitForRowLock IN     INTEGER     DEFAULT 1,
   store_name     IN     VARCHAR2    DEFAULT NULL,
   principal      IN     VARCHAR2    DEFAULT NULL);
```

Parameters

Table 57-77 UNLOCKPATH Procedure Parameters

Parameter	Description
path	Name of path to file items
who	Transaction identifier that has locked the path
waitForRowLock	Determines if a row is locked by a transaction or not
store_name	Name of store
principal	Agent (principal) invoking the current operation

Related Topics

- LOCKPATH Procedure
  This procedure applies user-level locks to the given valid path name (subject to store feature support), and optionally associates user-data with the lock.

57.7.66 UNMOUNTSTORE Procedure

This procedure unmounts a registered store, either by name or by mount point.

Syntax

```
DBMS_DBFS_CONTENT.UNMOUNTSTORE (
   store_name       IN      VARCHAR2   DEFAULT NULL,
   store_mount      IN      VARCHAR2   DEFAULT NULL,
   ignore_unknown   IN      BOOLEAN    DEFAULT FALSE);
```

Parameters

Table 57-78 UNMOUNTSTORE Procedure Parameters

Parameter	Description
store_name	Name of store
store_mount	Location at which the store instance is mounted
ignore_unknown	If TRUE, attempts to unregister unknown stores will not raise an exception.

Usage Notes

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on unmounting a previously unmounted store

57.7.67 UNREGISTERSTORE Procedure

This procedure unregisters a previously registered store (invalidating all mount points associated with it).

Syntax

```
DBMS_DBFS_CONTENT.UNREGISTERSTORE (
   store_name          IN      VARCHAR2,
   ignore_unknown      IN      BOOLEAN DEFAULT FALSE);
```

Parameters

Table 57-79 UNREGISTERSTORE Procedure Parameters

Parameter	Description
`store_name`	Name of store
`ignore_unknown`	If `TRUE`, attempts to unregister unknown stores will not raise an exception.

Usage Notes

- Once unregistered all access to the store (and its mount points) are not guaranteed to work
- If the `ignore_unknown` argument is `TRUE`, attempts to unregister unknown stores do not raise an exception.

58
DBMS_DBFS_CONTENT_SPI

The DBMS_DBFS_CONTENT_SPI package is a specification for DBMS_DBFS_CONTENT store providers, which must be implemented. Application designers can create PL/SQL packages conforming to this specification to extend DBMS_DBFS_CONTENT to use custom store providers.

This chapter contains the following topics:

- Overview
- Security Model
- Operational Notes
- Summary of DBMS_DBFS_CONTENT_SPI Subprograms

Related Topics

- DBMS_DBFS_CONTENT
  The DBMS_DBFS_CONTENT package provides an interface comprising a file system-like abstraction backed by one or more Store Providers.

> **See Also:**
>
> - *Oracle Database SecureFiles and Large Objects Developer's Guide*

58.1 ODBMS_DBFS_CONTENT_SPI Overview

The DBMS_DBFS_CONTENT_SPI package describes an internal contract between the implementation of the DBMS_DBFS_CONTENT interface and individual store providers, and whichever package contains their code.

Since PL/SQL does not allow a compile-time, declarative type-conformation between package signatures, store providers should informally conform to the SPI, which is to say, they should implement the SPI by means of a package that contains all of the methods specified in package DBMS_DBFS_CONTENT_SPI, with the same method signatures and semantics.

Obviously, these provider packages can implement other methods and expose other interfaces, however, these interfaces are not to be used by the DBMS_DBFS_CONTENT interface itself.

Since the provider SPI is merely a contract specification, there is no package body for DBMS_DBFS_CONTENT_SPI, and it is not possible to actually invoke any methods using this package.

The SPI references various elements (constants, types, exceptions) defined by the DBMS_DBFS_CONTENT interface.

Additionally, there is an almost one-to-one correspondence between the client API exported by the DBMS_DBFS_CONTENT interface and the provider interface that the DBMS_DBFS_CONTENT interface itself expects to work against.

The main distinction in the method naming conventions is that all path name references are always store-qualified. That is, the notion of mount-points and full-absolute path names have been normalized and converted to store-qualified path names by the DBMS_DBFS_CONTENT interface before it invokes any of the provider SPI methods.

Since the interconnection of the DBMS_DBFS_CONTENT interface and the provider SPI is a 1-to-many pluggable architecture, and the interface uses dynamic SQL to invoke methods in the provider SPI, this can lead to runtime errors.

Related Topics

- DBMS_DBFS_CONTENT
  The DBMS_DBFS_CONTENT package provides an interface comprising a file system-like abstraction backed by one or more Store Providers.

58.2 DBMS_DBFS_CONTENT_SPI Security Model

Implementations of the DBMS_DBFS_CONTENT_SPI package should be created as AUTHID CURRENT_USER.

58.3 DBMS_DBFS_CONTENT_SPI Operational Notes

This topic lists operational notes for DBMS_DBFS_CONTENT_SPI implementation, path names, and other operations.

- Implementation
- Path Names
- Other DBMS_DBFS_CONTENT Operations

Implementation

Since the interconnection of the DBMS_DBFS_CONTENT interface and the provider SPI is a 1-to-many pluggable architecture, the interface uses dynamic SQL to invoke methods in the provider SPI, this can lead to runtime errors.

There are no explicit INIT or FINI methods to indicate when the DBMS_DBFS_CONTENT interface plugs or unplugs a particular provider SPI. Provider SPIs must be willing to auto-initialize themselves at any SPI entry-point.

All operations performed by a store provider are "stateless" in that they are complete operations unto themselves. If state is necessary to be maintained for some reason, then the state must be maintained in data structures such as auxiliary tables that can be queried as needed.

Path Names

All path names used in the provider SPI are store-qualified in pair form (store_name, pathname) where the path name is rooted within the store namespace.

Stores and their providers that support contentID-based access (see FEATURE_CONTENT_ID in Table 57-5) also support a form of addressing that is not based

on path names. Content items are identified by an explicit store name, a `NULL` path name, and possibly a contentID specified as a parameter or by way of the `OPT_CONTENT_ID` (seeTable 57-8) property.

Not all operations are supported with contentID-based access, and applications should depend only on the simplest create or delete functionality being available.

Other DBMS_DBFS_CONTENT Operations

This table lists other operations and provides links to related discussions.

Table 58-1 Other DBMS_DBFS_CONTENT Operations

Other Operations	See ...
Creation	*Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on creation operations
Deletion	*Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on deletion operations
Get (Retrieve) and Put (Insert)	*Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on Get and Put operations
Rename and Move	*Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on Rename and Move operations
Directory Navigation and Search	*Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on Navigation and Search operations
Locking	*Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on Locking operations
Access Check	*Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on Access Check operations

58.4 Summary of DBMS_DBFS_CONTENT_SPI Subprograms

This table lists and describes the subprograms used in the `DBMS_DBFS_CONTENT_SPI` Package.

Table 58-2 DBMS_DBFS_CONTENT_SPI Package Subprograms

Subprogram	Description
CHECKACCESS Function	Reports if the user (`principal`) can perform the specified operation on the given path
CREATEDIRECTORY Procedure	Creates a directory
CREATEFILE Procedure	Creates a file
CREATELINK Procedure	Creates a physical link to an already existing file system element
CREATEREFERENCE Procedure	Creates a new reference to the source file system element
DELETECONTENT Procedure	Deletes the file specified by the given contentID
DELETEDIRECTORY Procedure	Deletes a directory
DELETEFILE Procedure	Deletes a file
GETFEATURES Function	Returns the features of a store
GETPATH Procedures	Returns existing path items (such as files and directories)

Table 58-2 (Cont.) DBMS_DBFS_CONTENT_SPI Package Subprograms

Subprogram	Description
GETPATHBYSTOREID Function	If the underlying GUID is found in the underlying store, returns the store-qualified path name
GETPATHNOWAIT Procedure	Implies that the operation is for an update, and, if implemented, allows providers to return an exception (`ORA-00054`) rather than wait for row locks.
GETSTOREID Function	Returns the ID of a store
GETVERSION Function	Returns the version associated with a store
LIST Function	Lists the contents of a directory path name
LOCKPATH Procedure	Applies user-level locks to the given valid path name
PURGEALL Procedure	Purges all soft-deleted entries matching the path and optional filter criteria
PURGEPATH Procedure	Purges any soft-deleted versions of the given path item
PUTPATH Procedures	Creates a new path item
RENAMEPATH Procedure	Renames or moves a path
RESTOREALL Procedure	Restores all soft-deleted path items meeting the path and filter criteria
RESTOREPATH Procedure	Restores all soft-deleted path items that match the given path and filter criteria
SEARCH Function	Searches for path items matching the given path and filter criteria
SETPATH Procedure	Assigns a path name to a path item represented by contentID
SPACEUSAGE Procedure	Queries file system space usage statistics
UNLOCKPATH Procedure	Unlocks path items that were previously locked with the LOCKPATH Procedure

58.4.1 CHECKACCESS Function

This function reports if the user (`principal`) can perform the specified operation on the given path. This enables verifying the validity of an operation without attempting to perform the operation. If `CHECKACCESS` returns 0, then the subprogram invoked to implement that operation should fail with an error.

Syntax

```
DBMS_DBFS_CONTENT_SPI.CHECKACCESS (
   store_name     IN     VARCHAR2  DEFAULT NULL,
   path           IN     VARCHAR2,
   pathtype       IN     INTEGER,
   operation      IN     VARCHAR2,
   principal      IN     VARCHAR2)
  RETURN  INTEGER;
```

Parameters

Table 58-3 CHECKACCESS Procedure Parameters

Parameter	Description
store_name	Name of store
path	Name of path to check for access
pathtype	Type of object path represents (see Table 57-4)
operation	Operation to be checked (see Table 57-8)
principal	File system user for whom the access check is made

Usage Notes

Whether or not the user invokes this function, a store that supports access control internally performs these checks to guarantee security.

58.4.2 CREATEDIRECTORY Procedure

This procedure creates a directory.

Syntax

```
DBMS_DBFS_CONTENT_SPI.CREATEDIRECTORY (
   store_name  IN              VARCHAR2,
   path        IN              VARCHAR2,
   properties  IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   prop_flags  IN              INTEGER,
   recurse     IN              INTEGER,
   ctx         IN              DBMS_DBFS_CONTENT_CONTEXT_T);
```

Parameters

Table 58-4 CREATEDIRECTORY Procedure Parameters

Parameter	Description
store_name	Name of store
path	Name of path to the directory
properties	One or more properties and their values to be set, returned, or both, depending on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)
prop_flags	Determines which properties are set, returned, or both. Default is PROP_STD. Specify properties to be returned by setting PROP_SPC (see Table 57-9), and providing an instance of the DBMS_DBFS_CONTENT_PROPERTIES_T Table Type with properties whose values are of interest.
recurse	If 0, do not execute recursively; otherwise, recursively create the directories above the given directory
ctx	Context with which to create the directory (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

58.4.3 CREATEFILE Procedure

This procedure creates a file.

Syntax

```
DBMS_DBFS_CONTENT_SPI.CREATEFILE (
   store_name    IN              VARCHAR2,
   path          IN              VARCHAR2,
   properties    IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   content       IN OUT NOCOPY   BLOB,
   prop_flags    IN              INTEGER,
   ctx           IN              DBMS_DBFS_CONTENT_CONTEXT_T);
```

Parameters

Table 58-5 CREATEFILE Procedure Parameters

Parameter	Description
`store_name`	Name of store
`path`	Name of path to the file
`properties`	One or more properties and their values to be set, returned or both depending, or both on `prop_flags` (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)
`content`	`BLOB` holding data with which to populate the file (optional)
`prop_flags`	Determines which properties are set, returned, or both. Default is `PROP_STD`. Specify properties to be returned by setting `prop_spec`, and providing an instance of the DBMS_DBFS_CONTENT_PROPERTIES_T Table Type with properties whose values are of interest.
`ctx`	Context with which to create the file (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

58.4.4 CREATELINK Procedure

This procedure creates a physical link to an already existing file system element (such as file or directory). The resulting entry shares the same metadata structures as the value of the `srcPath` parameter, and so is similar to incrementing a reference count on the file system element. This is analogous to a UNIX file system hard link.

Syntax

```
DBMS_DBFS_CONTENT_SPI.CREATELINK (
   store_name    IN              VARCHAR2,
   srcPath       IN              VARCHAR2,
   dstPath       IN              VARCHAR2,
   properties    IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   prop_flags    IN              INTEGER,
   ctx           IN              DBMS_DBFS_CONTENT_CONTEXT_T);
```

Parameters

Table 58-6 CREATELINK Procedure Parameters

Parameter	Description
store_name	Name of store
srcPath	File system entry with which to link
dstPath	Path of the new link element to be created
properties	One or more properties and their values to be set, returned, or both, depending on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)
prop_flags	Determines which properties are set, returned, or both. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the DBMS_DBFS_CONTENT_PROPERTIES_T Table Type with properties whose values are of interest.
ctx	Context with which to create the link (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

58.4.5 CREATEREFERENCE Procedure

This procedure creates a new reference to the source file system element (such as a file, or directory). The resulting reference points to the source element but does not directly share metadata with the source element. This is analogous to a UNIX file system symbolic link.

Syntax

```
DBMS_DBFS_CONTENT_SPI.CREATEREFERENCE (
   srcPath       IN              VARCHAR2,
   dstPath       IN              VARCHAR2,
   properties    IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   prop_flags    IN              INTEGER,
   store_name    IN              VARCHAR2,
   ctx           IN              DBMS_DBFS_CONTENT_CONTEXT_T);
```

Parameters

Table 58-7 CREATEREFERENCE Procedure Parameters

Parameter	Description
store_name	Name of store
srcPath	File system entry with which to link
dstPath	Path of the new link element to be created
properties	One or more properties and their values to be set, returned, or both, depending on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)

Table 58-7 (Cont.) CREATEREFERENCE Procedure Parameters

Parameter	Description
prop_flags	Determines which properties are set, returned, or both. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the DBMS_DBFS_CONTENT_PROPERTIES_T Table Type with properties whose values are of interest.
ctx	Context with which to create the reference (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

58.4.6 DELETECONTENT Procedure

This procedure deletes the file specified by the given contentID.

Syntax

```
DBMS_DBFS_CONTENT_SPI.DELETECONTENT (
   store_name     IN     VARCHAR2,
   contentID      IN     RAW,
   filter         IN     VARCHAR2,
   soft_delete    IN     INTEGER,
   ctx            IN     DBMS_DBFS_CONTENT_CONTEXT_T);
```

Parameters

Table 58-8 DELETECONTENT Procedure Parameters

Parameter	Description
store_name	Name of store
contentID	Unique identifier for the file to be deleted
filter	A filter, if any, to be applied
soft_delete	If 0, execute a hard (permanent) delete. For any value other than 0, perform a soft delete see *Oracle Database SecureFiles and Large Objects Developer's Guide*, Deletion Operations).
ctx	Context with which to delete the file (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

58.4.7 DELETEDIRECTORY Procedure

This procedure deletes a directory.

If recurse is nonzero, it recursively deletes all elements of the directory. A filter, if supplied, determines which elements of the directory are deleted.

Syntax

```
DBMS_DBFS_CONTENT_SPI.DELETEDIRECTORY (
   store_name     IN     VARCHAR2,
   path           IN     VARCHAR2,
   filter         IN     VARCHAR2,
   soft_delete    IN     INTEGER,
```

```
   recurse         IN     INTEGER,
   ctx             IN     DBMS_DBFS_CONTENT_CONTEXT_T);
```

Parameters

Table 58-9 DELETEDIRECTORY Procedure Parameters

Parameter	Description
store_name	Name of store
path	Name of path to the directory
filter	A filter, if any, to be applied
soft_delete	If 0, execute a hard (permanent) delete. For any value other than 0, perform a soft delete see *Oracle Database SecureFiles and Large Objects Developer's Guide*, Deletion Operations).
recurse	If 0, do not execute recursively. Otherwise, recursively delete the directories and files below the given directory.
ctx	Context with which to delete the directory (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

58.4.8 DELETEFILE Procedure

This procedure deletes the specified file.

Syntax

```
DBMS_DBFS_CONTENT_SPI.DELETEFILE (
   store_name      IN     VARCHAR2,
   path            IN     VARCHAR2,
   filter          IN     VARCHAR2,
   soft_delete     IN     BOOLEAN,
   ctx             IN     DBMS_DBFS_CONTENT_CONTEXT_T);
```

Parameters

Table 58-10 DELETEFILE Procedure Parameters

Parameter	Description
store_name	Name of store
path	Name of path to the file
filter	A filter, if any, to be applied
soft_delete	If 0, execute a hard (permanent) delete. For any value other than 0, perform a soft delete see *Oracle Database SecureFiles and Large Objects Developer's Guide*, Deletion Operations).
ctx	Context with which to delete the file (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

58.4.9 GETFEATURES Function

This function returns the features of a store.

Syntax

```
DBMS_DBFS_CONTENT_SPI.GETFEATURES (
   store_name          IN      VARCHAR2)
  RETURN  INTEGER;
```

Parameters

Table 58-11 GETFEATURES Function Parameters

Parameter	Description
store_name	Name of store

Return Values

DBMS_DBFS_CONTENT.FEATURE_* features supported by the Store Provider

58.4.10 GETPATH Procedures

This procedure returns existing path items (such as files and directories). This includes both data and metadata (properties).

The client can request (using prop_flags) that specific properties be returned. File path names can be read either by specifying a BLOB locator using the prop_data bitmask in prop_flags (see Table 57-9) or by passing one or more RAW buffers.

When forUpdate is 0, this procedure also accepts a valid "as of" timestamp parameter as part of ctx that can be used by stores to implement "as of" style flashback queries. Mutating versions of the GETPATH Procedures do not support these modes of operation.

Syntax

```
DBMS_DBFS_CONTENT_SPI.GETPATH (
   store_name  IN              VARCHAR2,
   path        IN              VARCHAR2,
   properties  IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   content     OUT    NOCOPY   BLOB,
   item_type   OUT             INTEGER,
   prop_flags  IN              INTEGER,
   forUpdate   IN              INTEGER,
   deref       IN              INTEGER,
   ctx         IN              DBMS_DBFS_CONTENT_CONTEXT_T);

DBMS_DBFS_CONTENT_SPI.GETPATH (
   store_name  IN              VARCHAR2,
   path        IN              VARCHAR2,
   properties  IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   amount      IN OUT          NUMBER,
   offset      IN              NUMBER,
   buffer      OUT    NOCOPY   RAW,
   prop_flags  IN              INTEGER,
```

```
   ctx         IN              DBMS_DBFS_CONTENT_CONTEXT_T);

DBMS_DBFS_CONTENT_SPI.GETPATH (
   store_name  IN              VARCHAR2,
   path        IN              VARCHAR2,
   properties  IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   amount      IN OUT          NUMBER,
   offset      IN              NUMBER,
   buffers     OUT    NOCOPY   DBMS_DBFS_CONTENT_RAW_T,
   prop_flags  IN              INTEGER,
   ctx         IN              DBMS_DBFS_CONTENT_CONTEXT_T);
```

Parameters

Table 58-12 GETPATH Procedure Parameters

Parameter	Description
store_name	Name of store
path	Name of path to path items
properties	One or more properties and their values to be returned depending on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)
content	BLOB holding data which populates the file (optional)
item_type	Type of the path item specified (see Table 57-4)
amount	On input, number of bytes to be read. On output, number of bytes read
offset	Byte offset from which to begin reading
buffer	Buffer to which to write
buffers	Buffers to which to write
prop_flags	Determines which properties are set, returned, or both. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the DBMS_DBFS_CONTENT_PROPERTIES_T Table Type with properties whose values are of interest.
forUpdate	Specifies that a lock should be taken to signify exclusive write access to the path item
deref	If nonzero, attempts to resolve the given path item to actual data provided it is a reference (symbolic link)
ctx	Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

58.4.11 GETPATHBYSTOREID Function

If the underlying GUID is found in the underlying store, this function returns the store-qualified path name.

Syntax

```
DBMS_DBFS_CONTENT_SPI.GETPATHBYSTOREID (
   store_name          IN      VARCHAR2,
   guid                IN      INTEGER)
  RETURN VARCHAR2;
```

Parameters

Table 58-13 GETPATHBYSTOREID Function Parameters

Parameter	Description
store_name	Name of store
guid	Unique ID representing the desired path item

Return Values

Store-qualified path name represented by the GUID

Usage Notes

If the STD_GUID is unknown, a NULL value is returned. Clients are expected to handle this as appropriate.

58.4.12 GETPATHNOWAIT Procedure

This procedure implies that the operation is for an update, and, if implemented, allows providers to return an exception (ORA-00054) rather than wait for row locks.

See FEATURE_NOWAIT in Table 57-5 for more information.

Syntax

```
DBMS_DBFS_CONTENT_SPI.GETPATHNOWAIT (
   store_name  IN              VARCHAR2,
   path        IN              VARCHAR2,
   properties  IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   content     OUT    NOCOPY   BLOB,
   item_type   OUT             INTEGER,
   prop_flags  IN              INTEGER,
   deref       IN              INTEGER,
   ctx         IN              DBMS_DBFS_CONTENT_CONTEXT_T);
```

Parameters

Table 58-14 GETPATHNOWAIT Procedure Parameters

Parameter	Description
store_name	Name of store
path	Name of path to path items
properties	One or more properties and their values to be returned depending on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)
content	BLOB holding data which populates the file (optional)
item_type	Type of the path item specified (see Table 57-4)

Table 58-14 (Cont.) GETPATHNOWAIT Procedure Parameters

Parameter	Description
prop_flags	Determines which properties are returned. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the DBMS_DBFS_CONTENT_PROPERTIES_T Table Type with properties whose values are of interest.
deref	If nonzero, attempts to resolve the given path item to actual data provided it is a reference (symbolic link)
ctx	Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

58.4.13 GETSTOREID Function

This function returns the ID of a store.

Syntax

```
DBMS_DBFS_CONTENT_SPI.GETSTOREID (
   store_name          IN      VARCHAR2)
  RETURN  NUMBER;
```

Parameters

Table 58-15 GETSTOREID Function Parameters

Parameter	Description
store_name	Name of store

Return Values

ID of the Store

Usage Notes

A store ID identifies a provider-specific store, across registrations and mounts, but independent of changes to the store contents. For this reason, changes to the store table or tables should be reflected in the store ID, but re-initialization of the same store table or tables should preserve the store ID.

58.4.14 GETVERSION Function

This function returns the version associated with a store.

Syntax

```
DBMS_DBFS_CONTENT_SPI.GETVERSION (
   store_name          IN      VARCHAR2)
  RETURN  VARCHAR2;
```

Parameters

Table 58-16 GETVERSION Function Parameters

Parameter	Description
store_name	Name of store

Return Values

A "version" (either specific to a provider package, or to an individual store) based on a standard *a.b.c* naming convention (for *major*, *minor*, and *patch* components)

58.4.15 ISPATHLOCKED Procedure

This procedure checks if any user-level locks are applied on a given path.

Syntax

```
DBMS_DBFS_CONTENT.ISPATHLOCKED (
   store_name     IN     VARCHAR2,
   path           IN     VARCHAR2,
   who            IN     VARCHAR2,
   lock_type      IN OUT INTEGER,
   ctx            IN     DBMS_DBFS_CONTENT_CONTEXT_T);
```

Parameters

Table 58-17 ISPATHLOCKED Procedure Parameters

Parameter	Description
store_name	Name of store
path	Path name of items to be locked
who	Transaction identifier that has locked the path
lock_type	One of the available lock types (see Table 57-6)
ctx	Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

58.4.16 LIST Function

This function lists the contents of a directory path name.

The invoker of the subprogram has the option to investigate recursively into sub-directories, to make soft-deleted items visible, to use a flashback "as of" a specified timestamp, and to filter items within the store based on list predicates.

Syntax

```
DBMS_DBFS_CONTENT_SPI.LIST (
   store_name     IN     VARCHAR2,
   path           IN     VARCHAR2,
   filter         IN     VARCHAR2,
   recurse        IN     INTEGER,
```

```
   ctx           IN     DBMS_DBFS_CONTENT_CONTEXT_T)
  RETURN  DBMS_DBFS_CONTENT_LIST_ITEMS_T PIPELINED;
```

Parameters

Table 58-18 LIST Function Parameters

Parameter	Description
store_name	Name of repository
path	Name of path to directories
filter	A filter, if any, to be applied
recurse	If 0, do not execute recursively. Otherwise, recursively list the contents of directories and files below the given directory.
ctx	Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

Return Values

Path items found that match the path, filter and criteria for executing recursively (see DBMS_DBFS_CONTENT_LIST_ITEMS_T Table Type)

Usage Notes

This function returns only list items; the client is expected to explicitly use one of the GETPATH Procedures to access the properties or content associated with an item.

58.4.17 LOCKPATH Procedure

This procedure applies user-level locks to the given valid path name (subject to store feature support), and optionally associates user-data with the lock.

Syntax

```
DBMS_DBFS_CONTENT_SPI.LOCKPATH (
   store_name     IN     VARCHAR2,
   path           IN     VARCHAR2,
   who            IN     VARCHAR2,
   lock_type      IN     INTEGER,
   waitForRowLock IN     INTEGER,
   ctx            IN     DBMS_DBFS_CONTENT_CONTEXT_T);
```

Parameters

Table 58-19 LOCKPATH Procedure Parameters

Parameter	Description
store_name	Name of store
path	Path name of items to be locked
who	Transaction identifier that has locked the path
lock_type	One of the available lock types (see Table 57-6)
waitForRowLock	Determines if a row is locked by a transaction or not

Table 58-19 (Cont.) LOCKPATH Procedure Parameters

Parameter	Description
ctx	Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

Usage Notes

- It is the responsibility of the store and its providers (assuming it supports user-defined lock checking) to ensure that lock and unlock operations are performed in a consistent manner.
- The status of locked items is available by means of various optional properties (see OPT_LOCK* in Table 57-8).

58.4.18 PURGEALL Procedure

This procedure purges all soft-deleted entries matching the path and optional filter criteria.

Syntax

```
DBMS_DBFS_CONTENT_SPI.PURGEALL (
   store_name     IN      VARCHAR2,
   path           IN      VARCHAR2,
   filter         IN      VARCHAR2,
   ctx            IN      DBMS_DBFS_CONTENT_CONTEXT_T);
```

Parameters

Table 58-20 PURGEALL Procedure Parameters

Parameter	Description
store_name	Name of store
path	Name of path to file items
filter	A filter, if any, to be applied based on specified criteria
ctx	Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

58.4.19 PURGEPATH Procedure

This procedure purges any soft-deleted versions of the given path item.

Syntax

```
DBMS_DBFS_CONTENT_SPI.PURGEPATH (
   path           IN      VARCHAR2,
   filter         IN      VARCHAR2,
   store_name     IN      VARCHAR2,
   ctx            IN      DBMS_DBFS_CONTENT_CONTEXT_T);
```

Parameters

Table 58-21 PURGEPATH Procedure Parameters

Parameter	Description
store_name	Name of store
path	Name of path to file items
filter	A filter, if any, to be applied
ctx	Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

58.4.20 PUTPATH Procedures

This procedure creates a new path item.

Syntax

```
DBMS_DBFS_CONTENT_SPI.PUTPATH (
   store_name    IN              VARCHAR2,
   path          IN              VARCHAR2,
   properties    IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   content       IN OUT NOCOPY   BLOB,
   item_type     OUT             INTEGER,
   prop_flags    IN              INTEGER,
   ctx           IN              DBMS_DBFS_CONTENT_CONTEXT_T);

DBMS_DBFS_CONTENT_SPI.PUTPATH (
   store_name    IN              VARCHAR2,
   path          IN              VARCHAR2,
   properties    IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   amount        IN              NUMBER,
   offset        IN              NUMBER,
   buffer        IN              RAW,
   prop_flags    IN              INTEGER,
   ctx           IN              DBMS_DBFS_CONTENT_CONTEXT_T);

DBMS_DBFS_CONTENT_SPI.PUTPATH (
   store_name    IN              VARCHAR2,
   path          IN              VARCHAR2,
   properties    IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   written       OUT             NUMBER,
   offset        IN              NUMBER,
   buffers       IN              DBMS_DBFS_CONTENT_RAW_T,
   prop_flags    IN              INTEGER,
   ctx           IN              DBMS_DBFS_CONTENT_CONTEXT_T);
```

Parameters

Table 58-22 PUTPATH Procedure Parameters

Parameter	Description
store_name	Name of store
path	Path name of item to be put

Table 58-22 (Cont.) PUTPATH Procedure Parameters

Parameter	Description
properties	One or more properties and their values to be set depending on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)
content	BLOB holding data which populates the file (optional)
item_type	Type of the path item specified (see Table 57-4)
amount	Number of bytes to be read
written	Number of bytes written
offset	Byte offset from which to begin reading
buffer	Buffer to which to write
buffers	Buffers to which to write
prop_flags	Determines which properties are set. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the DBMS_DBFS_CONTENT_PROPERTIES_T Table Type with properties whose values are of interest.
ctx	Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

Usage Notes

- All path names allow their metadata (properties) to be read and modified. On completion of the call, the client can access specific properties using prop_flags (see Table 57-9).
- On completion of the call, the client can request a new BLOB locator that can be used to continue data access using the prop_data bitmask in prop_flags (see Table 57-9).
- Files can also be written without using BLOB locators, by explicitly specifying logical offsets or buffer-amounts, and a suitably sized buffer.

58.4.21 RENAMEPATH Procedure

This procedure renames or moves a path. This operation can be performed across directory hierarchies and mount-points as long as it is within the same store.

> **Note:**
>
> See *Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on Rename and Move operations

Syntax

```
DBMS_DBFS_CONTENT_SPI.RENAMEPATH (
   store_name    IN              VARCHAR2,
   oldPath       IN              VARCHAR2,
   newPath       IN              VARCHAR2,
```

```
   properties    IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   ctx           IN              DBMS_DBFS_CONTENT_CONTEXT_T);
```

Parameters

Table 58-23 RENAMEPATH Procedure Parameters

Parameter	Description
store_name	Name of store, must be unique
oldPath	Name of path prior to renaming
newPath	Name of path after renaming
properties	One or more properties and their values to be set depending on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)
ctx	Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

58.4.22 RESTOREALL Procedure

This procedure restores all soft-deleted path items meeting the path and optional filter criteria.

Syntax

```
DBMS_DBFS_CONTENT_SPI.RESTOREALL (
   store_name     IN      VARCHAR2,
   path           IN      VARCHAR2,
   filter         IN      VARCHAR2,
   ctx            IN      DBMS_DBFS_CONTENT_CONTEXT_T);
```

Parameters

Table 58-24 RESTOREALL Procedure Parameters

Parameter	Description
store_name	Name of store
path	Name of path to path items
filter	A filter, if any, to be applied
ctx	Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

58.4.23 RESTOREPATH Procedure

This procedure restores all soft-deleted path items that match the given path and optional filter criteria.

Syntax

```
DBMS_DBFS_CONTENT_SPI.RESTOREPATH (
   store_name     IN      VARCHAR2,
   path           IN      VARCHAR2,
```

```
   filter          IN      VARCHAR2,
   ctx             IN      DBMS_DBFS_CONTENT_CONTEXT_T);
```

Parameters

Table 58-25 RESTOREPATH Procedure Parameters

Parameter	Description
store_name	Name of store
path	Name of path to path items
filter	A filter, if any, to be applied
ctx	Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

58.4.24 SEARCH Function

This function searches for path items matching the given path and filter criteria.

Syntax

```
DBMS_DBFS_CONTENT_SPI.SEARCH (
   store_name      IN      VARCHAR2,
   path            IN      VARCHAR2,
   filter          IN      VARCHAR2,
   recurse         IN      INTEGER,
   ctx             IN      DBMS_DBFS_CONTENT_CONTEXT_T)
 RETURN  DBMS_DBFS_CONTENT_LIST_ITEMS_T PIPELINED;
```

Parameters

Table 58-26 LIST Function Parameters

Parameter	Description
store_name	Name of store
path	Name of path to the path items
filter	A filter, if any, to be applied
recurse	If 0, do not execute recursively. Otherwise, recursively search the contents of directories and files below the given directory.
ctx	Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

Return Values

Path items matching the given path and filter criteria (see DBMS_DBFS_CONTENT_LIST_ITEMS_T Table Type)

58.4.25 SETPATH Procedure

This procedure assigns a path name to a path item represented by contentID.

Stores and their providers that support contentID-based access and lazy path name binding also support the `SETPATH Procedure` that associates an existing `contentID` with a new path.

> **Note:**
>
> See *Oracle Database SecureFiles and Large Objects Developer's Guide* for further information on Rename and Move operations

Syntax

```
DBMS_DBFS_CONTENT_SPI.SETPATH (
   store_name    IN              VARCHAR2,
   contentID     IN              RAW,
   path          IN              VARCHAR2,
   properties    IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,
   ctx           IN              DBMS_DBFS_CONTENT_CONTEXT_T);
```

Parameters

Table 58-27 SETPATH Procedure Parameters

Parameter	Description
`store_name`	Name of the store
`contentID`	Unique identifier for the item to be associated
`path`	Name of path to path item
`properties`	One or more properties and their values to be set depending on `prop_flags` (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)
`ctx`	Context with which to access the path items (seE DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

58.4.26 SPACEUSAGE Procedure

This procedure queries file system space usage statistics.

Providers are expected to support this subprogram for their stores and to make a best effort determination of space usage, especially if the store consists of multiple tables, indexes, LOBs, and so on.

Syntax

```
DBMS_DBFS_CONTENT_SPI.SPACEUSAGE (
   store_name    IN        VARCHAR2,
   blksize       OUT       INTEGER,
   tbytes        OUT       INTEGER,
   fbytes        OUT       INTEGER,
   nfile         OUT       INTEGER,
```

```
   ndir          OUT       INTEGER,
   nlink         OUT       INTEGER,
   nref          OUT       INTEGER);
```

Parameters

Table 58-28 SPACEUSAGE Procedure Parameters

Parameter	Description
store_name	Name of store
blksize	Natural tablespace blocksize that holds the store. If multiple tablespaces with different blocksizes are used, any valid blocksize is acceptable.
tbytes	Total size of the store in bytes computed over all segments that comprise the store
fbytes	Free or unused size of the store in bytes computed over all segments that comprise the store
nfile	Number of currently available files in the store
ndir	Number of currently available directories in the store
nlink	Number of currently available links in the store
nref	Number of currently available references in the store

Usage Notes

- A space usage query on the top-level root directory returns a combined summary of the space usage of all available distinct stores under it (if the same store is mounted multiple times, it is still counted only once).
- Since database objects are dynamically expandable, it is not easy to estimate the division between "free" space and "used" space.

58.4.27 UNLOCKPATH Procedure

This procedure unlocks path items that were previously locked with the LOCKPATH Procedure.

Syntax

```
DBMS_DBFS_CONTENT_SPI.UNLOCKPATH (
   store_name     IN     VARCHAR2,
   path           IN     VARCHAR2,
   who            IN     VARCHAR2,
   waitForRowLock IN     INTEGER,
   ctx            IN     DBMS_DBFS_CONTENT_CONTEXT_T);
```

Parameters

Table 58-29 UNLOCKPATH Procedure Parameters

Parameter	Description
store_name	Name of store
path	Name of path to the path items

Table 58-29 (Cont.) UNLOCKPATH Procedure Parameters

Parameter	Description
`who`	Transaction identifier that has locked the path
`waitForRowLock`	Determines if a row is locked by a transaction or not
`ctx`	Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)

Related Topics

- LOCKPATH Procedure
  This procedure applies user-level locks to the given valid path name (subject to store feature support), and optionally associates user-data with the lock.

59
DBMS_DBFS_HS

The Oracle Database File System Hierarchical Store is implemented in the `DBMS_DBFS_HS` package. This package provides users the ability to use tape or Amazon S3 Web service as a storage tier when doing Information Lifecycle Management for their database tables.

This chapter contains the following topics:

- Overview
- Security Model
- Constants
- Operational Notes
- Summary of DBMS_DBFS_HS Subprograms

> **See Also:**
>
> - *Oracle Database SecureFiles and Large Objects Developer's Guide*

59.1 DBMS_DBFS_HS Overview

The `DBMS_DBFS_HS` package is a service provider underneath the `DBMS_DBFS_CONTENT` package that enables use of tape or Amazon S3 Web service as storage for data.

The data on tape or Amazon S3 Web service is part of the Oracle Database and can be accessed through all standard interfaces, but only through the database. The package allows users to use tape or Amazon S3 Web service as a storage tier when doing Information Lifecycle Management of their content.

The package initially stores all content files in level-1 cache. As the level-1 cache fills up, content files are moved to level-2 cache and then to an external storage device using bulk writes.

59.2 DBMS_DBFS_HS Security Model

The `DBMS_DBFS_HS` package runs with invoker's rights.

59.3 DBMS_DBFS_HS Constants

The `DBMS_DBFS_HS` package uses the constants shown in the tables in this topic.

Table 59-1 DBMS_DBFS_HS Constants - Used by the CREATESTORE Procedure

Constant	Type	Value	Description
STORETYPE_TAPE	VARCHAR2(50)	'HS_TAPE'	Use tape as a storage tier
STORETYPE_AMAZONS3	VARCHAR2(50)	'HS_S3'	Use Amazon S3 Web service as a storage tier

Table 59-2 DBMS_DBFS_HS Constants - Used by the SETSTOREPROPERTY Procedure and the GETSTOREPROPERTY Function

Constant	Type	Value	Description
PROPNAME_BUCKET	VARCHAR2(50)	'BUCKET'	Specifies the AWS bucket to be used as a storage tier by the Hierarchical Store. Restrictions on bucket name are: 1) Bucket names can only contain lowercase letters, numbers, periods (.) and dashes(-). Note that underscores (_) are invalid. 2) Bucket names must start with a number or letter. 3) Bucket names cannot be in an IP address style (192.168.5.4). 4) Bucket names must be between 3 and 63 characters long. 5) Bucket names should not end with a dash. 6) Dashes cannot appear next to periods. For example, my-.bucket.com is invalid.
PROPNAME_CACHESIZE	VARCHAR2(50)	'CACHE_SIZE'	Specifies the cumulative cache size used for the Hierarchical Store. This property is set by the CREATESTORE Procedure and can be modified by the RECONFIGCACHE Procedure. It cannot be modified by the SETSTOREPROPERTY Procedure, though its value can be queried by the GETSTOREPROPERTY Function.
PROPNAME_COMPRESSLEVEL	VARCHAR2(50)	'COMPRESSION_LEVEL'	Use to enable compression of files stored in the DBFS hierarchical store. It specifies the compression level to be used for compressing the files

Table 59-2 (Cont.) DBMS_DBFS_HS Constants - Used by the SETSTOREPROPERTY Procedure and the GETSTOREPROPERTY Function

Constant	Type	Value	Description
PROPNAME_ENABLECLEANUPONDELETE	VARCHAR2(50)	'ENABLE_CLEANUP_ON_DELETE'	If this property is set to 'TRUE', whenever the user invokes the DELETEFILE Procedure in the DBMS_DBFS_CONTENT interface on a file residing in the DBMS_DBFS_HS store, the DBMS_DBFS_HS removes the file on the external storage that contains this user file, provided that the file has no other useful data.By default, the property is set to 'TRUE' for STORETYPE_AMAZONS3 and 'FALSE' for STORETYPE_TAPE.
PROPNAME_HTTPPROXY	VARCHAR2(50)	'HTTP_PROXY'	Specifies the DNS name of the HTTP proxy, if any, that is needed to access the Amazon S3 storage service
PROPNAME_LICENSEID	VARCHAR2(50)	'LICENSE_ID'	Specifies the license ID associated with the library libosbws11.so.
PROPNAME_LOBCACHE_QUOTA	VARCHAR2(50)	'LOBCACHE_QUOTA'	Specifies fraction of the cache_size which is allocated for level 1 cache. The default value of this parameter is NULL which means that 0.8 (= 80%) of the cache_size is used for level 1 cache. This property cannot be modified by the SETSTOREPROPERTY Procedurethough its value can be queried by the GETSTOREPROPERTY Function. Its value is set by CREATESTORE Procedure and can be modified by the RECONFIGCACHE Procedure.
PROPNAME_MEDIAPOOL	VARCHAR2(50)	'MEDIA_POOL'	Specifies the media pool number to use for storing the content
PROPVAL_COMPLVL_NONE	VARCHAR2(50)	'NONE'	Indicates no compression
PROPVAL_COMPLVL_LOW	VARCHAR2(50)	'LOW'	Use to set the compression level to LOW. This is expected to have the best performance while still providing a good compression ratio.
PROPVAL_COMPLVL_MEDIUM	VARCHAR2(50)	'MEDIUM'	Use to set the compression level to MEDIUM. This compression level is expected to provide better compression ratio than LOW but the time required for compression will be higher than compression level LOW.

Table 59-2 (Cont.) DBMS_DBFS_HS Constants - Used by the SETSTOREPROPERTY Procedure and the GETSTOREPROPERTY Function

Constant	Type	Value	Description
PROPVAL_COMPLVL_HIGH	VARCHAR2(50)	'HIGH'	Use to set the compression level to HIGH. This compression level is expected to provide the best compression ratio but compression time will in general be highest among the 3 compression levels.
PROPNAME_OPTTARBALLSIZE	VARCHAR2(50)	'OPTIMAL_TARBALL_SIZE'	Specifies optimal_tarball_size as the maximum possible size of an archive file. Multiple content files are bundled together into one archive file and then the archive file is transferred to tape or Amazon S3. This is because creating one file on tape or Amazon S3 for every content file in the store is a prohibitively expensive operation. This property cannot be modified by the SETSTOREPROPERTY Procedurethough its value can be queried by the GETSTOREPROPERTY Function. Its value is set by CREATESTORE Procedure and can be modified by the RECONFIGCACHE Procedure.
PROPNAME_READCHUNKSIZE	VARCHAR2(50)	'READ_CHUNK_SIZE'	Specifies the size used by the SBT protocol to transfer data from tape or S3.This chunk is allocated in memory per transaction for retrieval of content files from an archive store, so the value of this property should be conservative. The default size of 1MB is typically good for most users.
PROPNAME_S3HOST	VARCHAR2(50)	'S3_HOST'	Specifies the HOST name of the Amazon S3 storage service. It must be s3.amazonaws.com.
PROPNAME_SBT_LIBRARY	VARCHAR2(50)	'SBT_LIBRARY'	Specifies the path of the shared library used by RMAN to communicate with Amazon S3. It is named libosbws11.so and is available in rdbms/lib directory.
PROPNAME_STREAMABLE	VARCHAR2(50)	'STREAMABLE'	Indicates whether buffer-based PUT or GET should be done on this store. Valid values for are TRUE and FALSE. The default value of this property is TRUE.

Table 59-2 (Cont.) DBMS_DBFS_HS Constants - Used by the SETSTOREPROPERTY Procedure and the GETSTOREPROPERTY Function

Constant	Type	Value	Description
PROPNAME_WALLET	VARCHAR2(50)	'WALLET'	The value of this property should be of the form: LOCATION=file:*filename* CREDENTIAL_ALIAS=*access/secret_alias* PROXY_AUTH_ALIAS=*proxyusername/password alias* Defines the Oracle Wallet which contains the credentials of the Amazon S3 account associated with the store under consideration. LOCATION: The directory path that contains the Oracle wallet. The format is file:*directory-path* The format of wallet_path in Windows is, for example: file:c:\WINNT\Profiles*username*\WALLETS In UNIX or Linux it is, for example: file:/home/*username*/wallets When the package is executed in the Oracle database server, the wallet is accessed from the database server. PASSWORD: Defines the wallet password. If auto-login is enabled in wallet (this can be changed using the OWM utility), this parameter does not have to be specified. By default, the mkstore utility enables auto-login. CREDENTIAL_ALIAS: Defines the credential alias for ACCESS_KEY and SECRET_KEY
PROPNAME_WRITECHUNKSIZ	VARCHAR2(50)	'WRITE_CHUNK_SIZE'	Specifies the size used by the SBT protocol to transfer data to tape or S3. This chunk is allocated in memory per transaction for PUT of Content Files to an archive store so the value should be conservative. The default size of 1MB is typically good for most users.

Table 59-3 DBMS_DBFS_HS Constants - Used by the REGISTERSTORECOMMAND Function

Constant	Type	Value	Description
BEFORE_PUT	NUMBER	'1'	Specified operation must be performed before writing a SECUREFILE to the remote store
BEFORE_GET	NUMBER	'2'	Specified operation must be performed before a retrieval operation such as reading a SECUREFILE from the remote device

Table 59-4 DBMS_DBFS_HS Constants - Failure/Success/Error

Constant	Type	Value	Description
FAIL	NUMBER	'0'	Procedure or function did not execute successfully
SUCCESS	NUMBER	'1'	Procedure or function completed successfully
ERROR	NUMBER	'2'	Procedure or function returned an error

59.4 DBMS_DBFS_HS Operational Notes

When the DBMS_DBFS_HS package is executed in the Oracle database server, the wallet is accessed from the database server.

59.5 Summary of DBMS_DBFS_HS Subprograms

This table lists and describes the subprograms in the DBMS_DBFS_HS package.

Table 59-5 DBMS_DBFS_HS Package Subprograms

Subprogram	Description
CLEANUPUNUSEDBACKUPFILES Procedure	Removes files created on the external storage device that hold no currently used data
CREATEBUCKET Procedure	Creates an AWS bucket, associated with a store of type STORETYPE_AMAZONS3 into which the Hierarchical Store can then move data
CREATESTORE Procedure	Creates a new hierarchical store
DEREGSTORECOMMAND Function	Removes a command that had been previously associated with a store through the RECONFIGCACHE Procedure
DROPSTORE Procedure	Deletes a previously created hierarchical store
FLUSHCACHE Procedure	Flushes (writes out) dirty contents from the level-1 cache.
GETSTOREPROPERTY Function	Retrieves the values of a property of a store

Table 59-5 (Cont.) DBMS_DBFS_HS Package Subprograms

Subprogram	Description
RECONFIGCACHE Procedure	Reconfigures the parameters of the database cache used by the store
REGISTERSTORECOMMAND Procedure	Registers commands for a store with the Hierarchical Store to be sent to the Media Manager for the external storage device associated with the store
SENDCOMMAND Procedures	Sends a command to be executed on the external storage device's Media Manager
SETSTOREPROPERTY Procedure	Stores properties of a store in the database
STOREPUSH Procedure	Pushes locally staged data to the remote storage

59.5.1 CLEANUPUNUSEDBACKUPFILES Procedure

This procedure removes files created on the external storage device that hold no currently used data in them.

Syntax

```
DBMS_DBFS_HS.CLEANUPUNUSEDBACKUPFILES (
   store_name     IN     VARCHAR2);
```

Parameters

Table 59-6 CLEANUPUNUSEDBACKUPFILES Procedure Parameters

Parameter	Description
store_name	Name of store

Usage Notes

- The action of removing files from external storage device can not be rolled back.
- This method can be executed periodically to clear space on the external storage device. Asynchronously deleting content from the external storage device is useful because it has minimal impact on the OLTP performance. The periodic scheduling can be accomplished using the DBMS_SCHEDULER package.

59.5.2 CREATEBUCKET Procedure

This procedure creates an AWS bucket, associated with a store of type STORETYPE_AMAZONS3 into which the Hierarchical Store can then move data.

Syntax

```
DBMS_DBFS_HS.CREATEBUCKET  (
   store_name    IN     VARCHAR2);
```

Parameters

Table 59-7 CREATEBUCKET Procedure Parameters

Parameter	Description
store_name	Name of store

Usage Notes

- The PROPNAME_BUCKET property of the store should be set before this subprogram is called.
- Once this procedure has successfully created a bucket in Amazon S3, the bucket can only be deleted using out-of-band methods, such as logging-in to S3 and deleting data (directories, files, and other items) for the bucket.

59.5.3 CREATESTORE Procedure

This procedure creates a new hierarchical store store_name of type STORE_TYPE (STORETYPE_TAPE or STORETYPE_AMAZONS3) in schema schema_name (defaulting to the current schema) under the ownership of the invoking session user.

Syntax

```
DBMS_DBFS_HS.CREATESTORE  (
   store_name              IN     VARCHAR2,
   store_type              IN     VARCHAR2,
   tbl_name                IN     VARCHAR2,
   tbs_name                IN     VARCHAR2,
   cache_size              IN     NUMBER,
   lob_cache_quota         IN     NUMBER DEFAULT NULL,
   optimal_tarball_size    IN     NUMBER DEFAULT NULL,
   schema_name             IN     VARCHAR2 DEFAULT NULL);
```

Parameters

Table 59-8 CREATESTORE Procedure Parameters

Parameter	Description
store_name	Name of store
store_type	STORETYPE_TAPE or STORETYPE_AMAZONS3
tbl_name	Table for store entries
tbs_name	Tablespace for the store
cache_size	Amount of space used by the store to cache content in given tablespace
lob_cache_quota	Fraction of the cache_size which is allocated for level 1 cache. The default value of this parameter is NULL which means that 0.8 (= 80%) of the cache_size is used for level 1 cache.

Table 59-8 (Cont.) CREATESTORE Procedure Parameters

Parameter	Description
optimal_tarball_size	Maximum possible size of the archive file. Multiple content files are bundled together into one archive file, and then the archive file is transferred to tape or Amazon S3. This is because creating one file on tape or Amazon S3 for every content file in the store is a prohibitively expensive operation. The value of is set by default to 10GB for tape and to 100MB for Amazon S3.
schema_name	Schema for the store

Usage Notes

CREATESTORE() sets certain properties of the store to default values. The user can use the methods SETSTOREPROPERTY() and RECONFIGCACHE() to appropriately change the property values and to set other properties of the store.

- Store names must be unique for an owner. The same store names can be used for different stores owned by different owners.
- Once a table space has been specified to store the store's content in a database, it cannot be changed later.
- This subprogram will execute like a DDL statement, performing an automatic COMMIT before and after execution.
- Stores using DBMS_DBFS_HS must not use singleton mount. This means that the singleton parameter should be FALSE and the store_mount parameter should have a non-NULL value in a call to the DBMS_DBFS_CONTENT.MOUNTSTORE procedure.

59.5.4 DEREGSTORECOMMAND Function

This procedure removes a command that had been previously associated with a store through the REGISTERSTORECOMMAND Procedure.

Syntax

```
DBMS_DBFS_HS.DEREGSTORECOMMAND (
   store_name      IN     VARCHAR2,
   message         IN     VARCHAR2);
```

Parameters

Table 59-9 DEREGSTORECOMMAND Procedure Parameters

Parameter	Description
store_name	Name of store
message	Message to be deregistered

Usage Notes

If this subprogram successfully executes, its actions cannot be rolled back by the user. If the user wants to restore the previous state, the user must call the REGISTERSTORECOMMAND Procedure.

Related Topics

- REGISTERSTORECOMMAND Procedure
  This procedure registers commands for a store with the Hierarchical Store. These commands are sent to the Media Manager for the external storage device associated with the store.

59.5.5 DROPSTORE Procedure

This procedure deletes a previously created hierarchical store specified by name and owned by the invoking session user.

Syntax

```
DBMS_DBFS_HS.DROPSTORE  (
   store_name   IN     VARCHAR2,
   opt_flags    IN     INTEGER DEFAULT 0);
```

Parameters

Table 59-10 DROPSTORE Procedure Parameters

Parameter	Description
`store_name`	Name of store owned by the invoking session user
`opt_flags`	User can specify optional flags. If `DISABLE_CLEANUPBACKUPFILES` is specified as one of the optional flags, the call to the CLEANUPUNUSEDBACKUPFILES Procedure is not issued. By default, when this flag is not set, the procedure implicitly cleans-up all unused backup files.

Usage Notes

- The procedure executes like a DDL in that it auto-commits before and after its execution.
- If `CLEANUPBACKUPFILES` is disabled during the procedure, the user must resort to out-of-band techniques to cleanup unused backup files. No further invocations of `CLEANUPBACKFILES` for a dropped store are possible through hierarchical store.
- This subprogram will un-register the store from `DBMS_DBFS_CONTENT` package. All files in the given store are deleted from the store (Tape or Amazon S3 Web service). The database table holding the store's entries in the database, is also dropped by this subprogram.

59.5.6 FLUSHCACHE Procedure

This procedure flushes out dirty contents from level-1 cache, which can be locked, to level-2 cache, thereby freeing-up space in level 1 cache.

Syntax

```
DBMS_DBFS_HS.FLUSHCACHE  (
   store_name    IN     VARCHAR2);
```

Parameters

Table 59-11 FLUSHCACHE Procedure Parameters

Parameter	Description
store_name	Name of store

59.5.7 GETSTOREPROPERTY Function

This function retrieves the values of a property.

Syntax

```
DBMS_DBFS_HS.GETSTOREPROPERTY  (
   store_name      IN     VARCHAR2,
   property_name   IN     VARCHAR2,
   noexcp          IN     BOOLEAN DEFAULT FALSE) RETURN VARCHAR2;
```

Parameters

Table 59-12 GETSTOREPROPERTY Function Parameters

Parameter	Description
store_name	Name of store
property_name	Name of property
noexcp	If set to FALSE, raises an exception if the property does not exist in the database. If noexcp is set to TRUE, returns NULL if the property does not exist.

Return Values

The values of a property.

Usage Notes

The specified store must already have been created.

59.5.8 RECONFIGCACHE Procedure

This procedure reconfigures the parameters of the database cache being used by the store.

Syntax

```
DBMS_DBFS_HS.RECONFIGCACHE (
   store_name              IN    VARCHAR2,
   cache_size              IN    NUMBER DEFAULT NULL,
   lobcache_quota          IN    NUMBER DEFAULT NULL,
   optimal_tarball_size    IN    NUMBER DEFAULT NULL);
```

Parameters

Table 59-13 RECONFIGCACHE Procedure Parameters

Parameter	Description
store_name	Name of store
cache_size	Cumulative cache size used for the Hierarchical Store
lobcache_quota	Fraction of the cache size that are assigned to level 1 cache
optimal_tarball_size	Maximum possible size of an archive file. Since creating one file for every content file in the store is a prohibitively expensive operation, multiple content files are bundled together into one archive file for transfer to tape or Amazon S3.

Usage Notes

- The specified store must already have been created before reconfiguration.
- The Hierarchical Store uses a level 1 cache and a level 2 cache. The level 1 cache subsumes most of the working set and the level 2 cache is used to perform bulk writes to the backend device.
- If any of the last 3 parameters is NULL, its value specified during store creation is used. If the parameter was NULL when the call to the CREATESTORE Procedure was issued, the DBMS_DBFS_HS package assigns a default value.

  The DBMS_DBFS_HS package optimistically tries to allocate more than 1 tarball's worth of size for level 2 cache to facilitate concurrency, though a minimum of 1 tarball size is necessary for level 2 cache.

  The values for cumulative cache size and LOB cache quota decide allocation of space for the two caches. If values are not provided, a user might see an INSUFFICIENT_CACHE exception. In that case, it is better to revise the cache parameters in order to have a working store.
- If this subprogram successfully executes, its actions cannot be rolled back by the user. In that case, the user should call RECONFIGCACHE again with new or modified parameters.

59.5.9 REGISTERSTORECOMMAND Procedure

This procedure registers commands for a store with the Hierarchical Store. These commands are sent to the Media Manager for the external storage device associated with the store.

Syntax

```
DBMS_DBFS_HS.REGISTERSTORECOMMAND (
   store_name      IN     VARCHAR2,
   message         IN     VARCHAR2,
   flags           IN     NUMBER);
```

Parameters

Table 59-14 REGISTERSTORECOMMAND Procedure Parameters

Parameter	Description
`store_name`	Name of store
`message`	Message to be sent to the Media Manager of the external store
`flags`	Valid values: • `BEFORE_PUT CONSTANT NUMBER := 1;` • `BEFORE_GET CONSTANT NUMBER := 2;`

Usage Notes

- These commands are sent before the next read or write of content. When the Hierarchical Store wants to push (or get) data to (or from) the storage device, it begins a session (to communicate with the device). After beginning the session, it sends all registered commands for the to the relevant device before writing (or getting) any data.
- If this method successfully executes, its actions cannot be rolled back by the user. To restore the previous state the user must call the DEREGSTORECOMMAND Function.

59.5.10 SENDCOMMAND Procedure

This procedure sends a command to be executed on the external storage device's Media Manager.

Syntax

```
DBMS_DBFS_HS.SENDCOMMAND (
   store_name    IN       VARCHAR2,
   message       IN       VARCHAR2);
```

Parameters

Table 59-15 SENDCOMMAND Procedure Parameters

Parameter	Description
`store_name`	Name of store
`message`	Message string to be executed

59.5.11 SETSTOREPROPERTY Procedure

This procedure stores properties of a store in the database as name-value pairs.

Syntax

```
DBMS_DBFS_HS.SETSTOREPROPERTY  (
   store_name      IN     VARCHAR2,
   property_name   IN     VARCHAR2,
   property_value  IN     VARCHAR2);
```

Parameters

Table 59-16 SETSTOREPROPERTY Procedure Parameters

Parameter	Description
store_name	Name of store
property_name	For a store using Tape device, there are three properties whose values must be set by the user, and four properties that have default values. Stores of type STORETYPE_AMAZONS3 have properties with default values. The various options for both types of stores are detailed under property_value.
property_value	**Stores using a Tape Device** The values for the following properties must be set by the user: • PROPNAME_SBTLIBRARY - This should point to the shared library used by RMAN to communicate with the external tape device. It is usually named libobk.so. • PROPNAME_MEDIAPOOL - Media pool number for storing content • PROPNAME_CACHE_SIZE - Amount of space, in bytes, used for the cache of this store The following properties, which have default values assigned to them when a store is created, benefit from tuning: • PROPNAME_READCHUNKSIZE and PROPNAME_WRITECHUNKSIZE - These are the sizes used by the SBT protocol to transfer data to and from the tapes. These chunks are allocated in memory per transaction, so the values should be conservative. The default size is 1MB. • PROPNAME_STREAMABLE – Indicates whether DBFS_LINKs can perform read operations (for example SELECT or DBMS_LOB.READ) directly from the store, or if the data must be copied back into the database before it can be read • PROPNAME_ENABLECLEANUPONDELETE - Indicates if DBMS_DBFS_HS should delete unused files on the external storage. Valid values for this property are 'FALSE' for STORETYPE_TAPE. • PROPNAME_COMPRESSLEVEL - Describes how files written to Tape should be compressed. It can be set to PROPVAL_COMPLVL_NONE, PROPVAL_COMPLVL_LOW, PROPVAL_COMPLVL_MEDIUM or PROPVAL_COMPLVL_HIGH. By default it is set to PROPVAL_COMPLVL_NONE.

Table 59-16 (Cont.) SETSTOREPROPERTY Procedure Parameters

Parameter	Description
(cont) property_value	**Stores of type STORETYPE_AMAZONS3** It is mandatory that the following properties have assigned values, and default values are provided: • PROPNAME_SBTLIBRARY - Specifies the path of the shared library used by RMAN to communicate with Amazon S3. It is named libosbws11.so and is available in rdbms/lib directory. • PROPNAME_S3HOST - Defines the HOST name of the Amazon S3 storage service. It must be s3.amazonaws.com. • PROPNAME_BUCKET - Defines the AWS bucket used as a storage tier by the Hierarchical Store. Restrictions on bucket names are: -- Bucket names can only contain lowercase letters, numbers, periods (.) and dashes (-). Use of an underscore (_) is invalid. -- Bucket names must start with a number or letter -- Bucket names cannot be in an IP address style ("192.168.5.4") -- Bucket names must be between 3 and 63 characters in length -- Bucket names should not end with a dash -- Dashes cannot appear next to periods. For example, "my-.bucket.com" is invalid. • PROPNAME_LICENSEID - Specifies the license ID associated with the library libosbws11.so. • PROPNAME_WALLET - Has the form: 'LOCATION=file:<filename> CREDENTIAL_ALIAS=<access/secret_alias> PROXY_AUTH_ALIAS=<proxyusername/password alias>' -- LOCATION - Directory path that contains the Oracle wallet. The format is file:*directory-path*. See Examples for variations in format. -- PASSWORD - Defines the wallet password. If auto-login is enabled in the wallet (this can be changed using the user's own utility), and does not have to be specified. By default, the mkstore utility enables auto-login. -- CREDENTIAL_ALIAS - Defines the credential alias for ACCESS_KEY and SECRET_KEY -- PROXY_AUTH_ALIAS - Defines authentication credentials for the proxy server, if applicable.

Table 59-16 (Cont.) SETSTOREPROPERTY Procedure Parameters

Parameter	Description
(property_value (contd.)	The following properties are optional: • PROPNAME_HTTPPROXY - Defines the DNS name of the HTTP proxy, if any, that is needed to access the Amazon S3 storage service. • PROPNAME_STREAMABLE – Indicates whether buffer-based PUT or GET operation should be done on this store. Valid values for this property are TRUE (default) and FALSE. • PROPNAME_ENABLECLEANUPONDELETE - Indicates if DBMS_DBFS_HS should delete unused files on the external storage device. Default values for this property are FALSE for STORETYPE_TAPE and TRUE for STORETYPE_AMAZONS3. • PROPNAME_COMPRESSLEVEL - Describes how files written to tape should be compressed. It can be set to PROPVAL_COMPLVL_NONE, PROPVAL_COMPLVL_LOW, PROPVAL_COMPLVL_MEDIUM or PROPVAL_COMPLVL_HIGH. By default it is set to PROPVAL_COMPLVL_NONE.

Usage Notes

- The specified store must already have been created.
- If this subprogram successfully executes, its actions cannot be rolled back by the user.
- The same property can be set multiple times to the same or different values using this subprogram
- Regarding PROPNAME_ENABLECLEANUPONDELETE behavior, a job is created for each store by the DBMS_DBFS_HS to remove the unused files from the external storage. By default, the job is enabled for STORETYPE_AMAZONS3 and is disabled for STORETYPE_TAPE. If the ENABLECLEANUPONDELETE property is set to TRUE, the job is enabled; if the property is set to FALSE, the job is disabled. If enabled, the job runs at an interval of one hour by default. The DBMS_SCHEDULER package can be used to modify the schedule. The name of the job can be obtained by querying USER_DBFS_HS_FIXED_PROPERTIES for prop_name = 'DELJOB_NAME'.

Examples

Format

The format of wallet_path in Windows is, for example:

```
file:c:\WINNT\Profiles\<username>\WALLETS
```

The format of wallet_path in UNIX or Linux is, for example:

```
file:/home/username/wallets
```

59.5.12 STOREPUSH Procedure

This procedure pushes locally staged data to the remote storage.

Syntax

```
DBMS_DBFS_HS.STOREPUSH (
   store_name   IN        VARCHAR2,
   path         IN        VARCHAR2 DEFAULT NULL);
```

Parameters

Table 59-17 STOREPUSH Procedure Parameters

Parameter	Description
`store_name`	Name of store whose content the client writes from local cache to the external store
`path`	A non-mount qualified (without mount point) path within the store. By default, its value is `NULL` which corresponds to the root path of the store.

Usage Notes

- The Hierarchical Store caches the content files locally in database tables. When enough content is amassed in the cache to make it efficient to write to the external storage device (or the cache is completely filled), the Hierarchical Store creates a tarball out of the local content and writes these tarballs as files on the external device. The size of the tarball created by the Hierarchical Store is controlled by the store property `PROPNAME_OPTTARBALLSIZE`.
- When the amount of free space in the cache is such that the caching of a content file will push the space used above `cache_size`, the Hierarchical Store will internally call `STOREPUSH`. The `STOREPUSH Procedure` creates tarball(s) out of the existing dirty or modified content files in the cache and writes them out to the external device. A `STOREPUSH` call is not guaranteed to write all the dirty content from local cache to the external storage, since some files may be locked by other sessions.
- `STOREPUSH` has a built-in ability feature allowing it to automatically resume operation. If a `STOREPUSH` call is interrupted (say by a network outage) after it has transferred some tarballs to the external device, it can be restarted after the outage and will then resume transferring data from the point it was interrupted. In other words, work done before the outage is not lost. `STOREPUSH` can safely be restarted and the effect is such as if the outage never occurred.
- If this method successfully executes, its actions cannot be rolled back by the user.
- By default, when `path` is `NULL`, all files in the store are candidates for `STOREPUSH`. If `path` has a valid input value, all files which are under the namespace of given path are written from the local cache to the external store. If a given path is an existing file, it is pushed out again to the remote store.

60
DBMS_DBFS_SFS

The DBMS_DBFS_SFS package provides an interface to operate a SecureFile-based store (SFS) for the content interface described in the DBMS_DBFS_CONTENT package.

This chapter contains the following topics:

- Overview
- Security Model
- Constants
- Summary of DBMS_DBFS_SFS Subprograms

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide*

60.1 DBMS_DBFS_SFS Overview

The DBMS_DBFS_SFS package is a sample implementation of a package that implements and extends the DBMS_DBFS_CONTENT_SPI interface. It provides a POSIX-compliant file system stored in the RDBMS.

60.2 DBMS_DBFS_SFS Security Model

The DBMS_DBFS_SFS package runs with AUTHID CURRENT_USER.

60.3 DBMS_DBFS_SFS Constants

The DBMS_DBFS_SFS package uses the constants shown in the following tables.

> **Note:**
>
> Oracle has deprecated the older encryptions and hashing algorithms. The deprecated algorithms for DBMS_CRYPTO and native network encryption include MD4, MD5, DES, 3DES, and RC4-related algorithms as well as 3DES for Transparent Data Encryption (TDE). Removing older, less secure cryptography algorithms prevents accidental use of these algorithms. To meet your security requirements, Oracle recommends that you use more modern cryptography algorithms, such as the Advanced Encryption Standard (AES).

- Table 60-1

- Table 60-2
- Table 60-3
- Table 60-4

Table 60-1 DBMS_DBFS_SFS Constants - Compression Levels

Constant	Type	Value	Description
COMPRESSION_DEFAULT	VARCHAR2(32)	''	Use the default SecureFile compression level
COMPRESSION_LOW	VARCHAR2(32)	'LOW'	Use compression level 'LOW'
COMPRESSION_MEDIUM	VARCHAR2(32)	'MEDIUM'	Use compression level 'MEDIUM'
COMPRESSION_HIGH	VARCHAR2(32)	'HIGH'	Use compression level 'HIGH'

Table 60-2 DBMS_DBFS_SFS Constants - Used by the encryption Parameter

Constant	Type	Value	Description
ENCRYPTION_DEFAULT	VARCHAR2(32)	''	Use the default SecureFile encryption algorithm
ENCRYPTION_AES128	VARCHAR2(32)	'AES128'	Use encryption AES 128 bit
ENCRYPTION_AES192	VARCHAR2(32)	'AES192'	Use encryption AES 192 bit
ENCRYPTION_AES256	VARCHAR2(32)	'AES256'	Use encryption AES 256 bit

Table 60-3 DBMS_DBFS_SFS Constants - Used by the npartitions Parameter

Constant	Type	Value	Description
DEFAULT_PARTITIONS	INTEGER	16	Default to 16 partitions

Table 60-4 DBMS_DBFS_SFS Constants - Used by the partition_key Parameter

Constant	Type	Value	Description
PARTITION_BY_ITEM	INTEGER	1	Use a hash of the item name for the partition key
PARTITION_BY_PATH	INTEGER	2	Use a hash of the path name for the partition key
PARTITION_BY_GUID	INTEGER	3	Use a hash of the GUID as the partition key

60.4 Summary of DBMS_DBFS_SFS Subprograms

This table lists and describes the DBMS_DBFS_SFS Package subprograms.

Table 60-5 DBMS_DBFS_SFS Package Subprograms

Subprogram	Description
CREATEFILESYSTEM Procedure	Creates a file system store
CREATESTORE Procedure	Creates a new DBFS SFS store
DROPFILESYSTEM Procedures	Drops the DBFS SFS store
INITFS Procedure	Initializes a POSIX file system store

60.4.1 CREATEFILESYSTEM Procedure

This procedure creates a file system store.

Syntax

```
DBMS_DBFS_SFS.CREATEFILESYSTEM (
   store_name         IN     VARCHAR2,
   schema_name        IN     VARCHAR2    DEFAULT NULL,
   tbl_name           IN     VARCHAR2    DEFAULT NULL,
   tbl_tbs            IN     VARCHAR2    DEFAULT NULL,
   lob_tbs            IN     VARCHAR2    DEFAULT NULL,
   use_bf             IN     BOOLEAN     DEFAULT FALSE,
   properties         IN     DBMS_DBFS_CONTENT_PROPERTIES_T DEFAULT NULL,
   create_only        IN     BOOLEAN     FALSE,
   use_objects        IN     BOOLEAN     DEFAULT FALSE,
   with_grants        IN     BOOLEAN     DEFAULT FALSE,
   do_dedup           IN     BOOLEAN     DEFAULT FALSE,
   do_compress        IN     BOOLEAN     DEFAULT FALSE
   compression        IN     VARCHAR2    DEFAULT COMPRESSION_DEFAULT,
   do_encrypt         IN     BOOLEAN     DEFAULT FALSE,
   encryption         IN     VARCHAR2    DEFAULT ENCRYPTION_DEFAULT,
   do_partition       IN     BOOLEAN     DEFAULT FALSE,
   npartitions        IN     NUMBER      DEFAULTDEFAULT_PARTITIONS,
   partition_key      IN     NUMBER      DEFAULT PARTITION_BY_ITEM,
   partition_guidi    IN     BOOLEAN     DEFAULT FALSE,
   partition_pathi    IN     BOOLEAN     DEFAULT FALSE,
   partition_prop     IN     BOOLEAN     DEFAULT TRUE);
```

Parameters

Table 60-6 CREATEFILESYSTEM Procedure Parameters

Parameter	Description
store_name	Name of store
schema_name	Schema for the store, defaulting to the current schema
tbl_name	Table for store entries. If not specified, an internally generated name is used.
tbl_tb	Tablespace for the store, defaulting to the schema's default tablespace
lob_tbs	Tablespace in which to create the LOB segment. It defaults to the user's default tablespace.
use_bf	If TRUE, a BasicFile LOB is used; otherwise a SecureFile LOB is used.

Table 60-6 (Cont.) CREATEFILESYSTEM Procedure Parameters

Parameter	Description
properties	Table of (name, value, typecode) tuples used to configure the store properties. Currently no such properties are defined or used.
create_only	If TRUE, the file system is created, but not registered with the current user
use_objects	If TRUE, a single base-table with an object-type column (using a nested table) is created to backup the new file system. Otherwise, a pair of (parent, child) tables is used to backup the file system. In both cases, the object type nested table or the child table is used only for user-defined properties.
with_grants	If TRUE, DML and query access permissions are granted to the DBFS_ROLE as part of creating the file system. Otherwise, explicit grants (or existing permissions) are required to access the file system.
do_dedup	If TRUE, do deduplication the underlying SecureFile column
do_compress	If TRUE, do compression the underlying SecureFile column
compression	Compression algorithm to use (see Table 60-1)
do_encrypt	If TRUE, encrypt the underlying SecureFile column
encryption	encryption algorithm to use (see Table 60-2)
do_partition	If TRUE, partition the table used for storage
npartitions	Number of partitions to create for the table (see Table 60-3).
partition_key	How to partition the table: by item name, by path name, or by GUID (see Table 60-4).
partition_guidi	If TRUE, build an index on GUID
partition_pathi	If TRUE, build an index on path name
partition_prop	If TRUE, partition the properties table

Usage Notes

The procedure executes like a DDL in that it auto-commits before and after its execution.

60.4.2 CREATESTORE Procedure

This procedure creates a new DBFS SFS store owned by the invoking session user.

Syntax

```
DBMS_DBFS_SFS.CREATESTORE  (
   store_name     IN     VARCHAR2,
   tbl_name       IN     VARCHAR2  DEFAULT NULL,
   tbs_name       in     VARCHAR2  DEFAULT NULL,
   use_bf         in     BOOLEAN   DEFAULT FALSE,
   stgopts        in     VARCHAR2 DEFAULT '');
```

Parameters

Table 60-7 CREATESTORE Procedure Parameters

Parameter	Description
store_name	Name of store
store_type	STORETYPE_TAPE or STORETYPE_AMAZONS3
tbl_name	Placeholder for the store content cached in database
tbs_name	Named tablespace
use_bf	If TRUE, a BasicFile LOB is used; otherwise a SecureFile LOB is used.
stgopts	Currently non-operational, reserved for future use

60.4.3 DROPFILESYSTEM Procedures

This procedure drops the DBFS SFS store, purging all dictionary information associated with the store, and dropping the underlying file system table.

Syntax

```
DBMS_DBFS_SFS.DROPFILESYSTEM  (
   schema_name    IN      VARCHAR2 DEFAULT NULL,
   tbl_name       IN      INTEGER);

DBMS_DBFS_SFS.DROPFILESYSTEM  (
   store_name     IN      VARCHAR2);
```

Parameters

Table 60-8 DROPFILESYSTEM Procedure Parameters

Parameter	Description
schema_name	Name of schema
tbl_name	Name of tablespace
store_name	Name of store path

Usage Notes

- If the specified store table is registered by the current user, it will be unregistered from the content interface described in the DBMS_DBFS_CONTENT package and the POSIX metadata tables.
- Subsequent to unregistration, an attempt will be made to store table(s). This operation may fail if other users are currently using this store table.
- The user attempting a drop of the tables underlying the store must actually have the privileges to complete the drop operation (either as the owner of the tables, or as a sufficiently privileged user for cross-schema operations).
- The procedure executes like a DDL in that it auto-commits before and after its execution.

60.4.4 INITFS Procedure

This procedure initialize a POSIX file system store. The table associated with the POSIX file system store `store_name` is truncated and reinitialized with a single "root" directory entry.

Syntax

```
DBMS_DBFS_SFS.INITFS (
   store_name     IN      VARCHAR2);
```

Parameters

Table 60-9 INITFS Procedure Parameters

Parameter	Description
`store_name`	Name of store

Usage Notes

The procedure executes like a DDL in that it auto-commits before and after its execution.

61
DBMS_DDL

This package provides access to some SQL data definition language (DDL) statements from stored procedures. It also provides special administration operations that are not available as Data Definition Language statements (DDLs).

This chapter contains the following topics:

- Deprecated Subprograms
- Security Model
- Operational Notes
- Summary of DBMS_DDL Subprograms

61.1 DBMS_DDL Deprecated Subprograms

Oracle recommends that you do not use deprecated subprograms in new applications. Support for deprecated features is for backward compatibility only

The following subprograms are deprecated with release Oracle Database 10*g*:

- ALTER_COMPILE Procedure

61.2 DBMS_DDL Security Model

This package runs with the privileges of the calling user, rather than the package owner `SYS`.

61.3 **DBMS_DDL** Operational Notes

The `ALTER_COMPILE` procedure commits the current transaction, performs the operation, and then commits again.

61.4 Summary of DBMS_DDL Subprograms

This table lists the `DDBMS_DDL` subprograms in alphabetical order and briefly describes them

Table 61-1 ***DBMS_DDL Package Subprograms***

Subprogram	Description
ALTER_COMPILE Procedure	Compiles the PL/SQL object
ALTER_TABLE_NOT_REFERENCEABLE Procedure	Reorganizes object tables
ALTER_TABLE_REFERENCEABLE Procedure	Reorganizes object tables

Table 61-1 (Cont.) *DBMS_DDL Package Subprograms*

Subprogram	Description
CREATE_WRAPPED Procedures	Takes as input a single CREATE OR REPLACE statement that specifies creation of a PL/SQL package specification, package body, function, procedure, type specification or type body, generates a CREATE OR REPLACE statement with the PL/SQL source text obfuscated and executes the generated statement
IS_TRIGGER_FIRE_ONCE Function	Returns TRUE if the specified DML or DDL trigger is set to fire once. Otherwise, returns FALSE
SET_TRIGGER_FIRING_PROPERTY Procedures	Sets the specified DML or DDL trigger's firing property
WRAP Functions	Takes as input a CREATE OR REPLACE statement that specifies creation of a PL/SQL package specification, package body, function, procedure, type specification or type body and returns a CREATE OR REPLACE statement where the text of the PL/SQL unit has been obfuscated

61.4.1 ALTER_COMPILE Procedure

This procedure is equivalent to the SQL statement: `ALTER PROCEDURE|FUNCTION|PACKAGE [<schema>.] <name> COMPILE [BODY]`

> **Note:**
>
> This procedure is deprecated in Oracle Database 10*g* Release 2 (10.2) While the procedure remains available in the package for reasons of backward compatibility, Oracle recommends using the DDL equivalent in a dynamic SQL statement.

Syntax

```
DBMS_DDL.ALTER_COMPILE (
   type             VARCHAR2,
   schema           VARCHAR2,
   name             VARCHAR2
   reuse_settings   BOOLEAN := FALSE);
```

Parameters

Table 61-2 ALTER_COMPILE Procedure Parameters

Parameter	Description
type	Must be either PROCEDURE, FUNCTION, PACKAGE, PACKAGE BODY or TRIGGER
schema	Schema name If NULL, then use current schema (case-sensitive)

Table 61-2 (Cont.) ALTER_COMPILE Procedure Parameters

Parameter	Description
name	Name of the object (case-sensitive)
reuse_settings	Indicates whether the session settings in the objects should be reused, or whether the current session settings should be adopted instead

Exceptions

Table 61-3 ALTER_COMPILE Procedure Exceptions

Exception	Description
ORA-20000:	Insufficient privileges or object does not exist
ORA-20001:	Remote object, cannot compile
ORA-20002:	Bad value for object type: should be either PACKAGE, PACKAGE BODY, PROCEDURE, FUNCTION, or TRIGGER

61.4.2 ALTER_TABLE_NOT_REFERENCEABLE Procedure

This procedure alters the given object table table_schema.table_name so it becomes not the default referenceable table for the schema affected_schema.

This is equivalent to SQL:

```
ALTER TABLE [<table_schema>.]<table_name> NOT REFERENCEABLE FOR <affected_schema>
```

which is currently not supported or available as a DDL statement.

Syntax

```
DBMS_DDL.ALTER_TABLE_NOT_REFERENCEABLE (
   table_name        IN           VARCHAR2,
   table_schema      IN  DEFAULT  NULL,
   affected_schema   IN  DEFAULT  NULL);
```

Parameters

Table 61-4 ALTER_TABLE_NOT_REFERENCEABLE Procedure Parameters

Parameter	Description
table_name	Name of the table to be altered. Cannot be a synonym. Must not be NULL. Case sensitive.
table_schema	Name of the schema owning the table to be altered. If NULL then the current schema is used. Case sensitive.
affected_schema	Name of the schema affected by this alteration. If NULL then the current schema is used. Case sensitive.

Usage Notes

This procedure simply reverts for the affected schema to the default table referenceable for PUBLIC; that is., it simply undoes the previous ALTER_TABLE_REFERENCEABLE call for this specific schema. The affected schema must a particular schema (cannot be PUBLIC).

The user that executes this procedure must own the table (that is, the schema is the same as the user), and the affected schema must be the same as the user.

If the user executing this procedure has ALTER ANY TABLE and SELECT ANY TABLE and DROP ANY TABLE privileges, the user doesn't have to own the table and the affected schema can be any valid schema.

61.4.3 ALTER_TABLE_REFERENCEABLE Procedure

This procedure alters the given object table table_schema.table_name so it becomes the referenceable table for the given schema affected_schema.

This is equivalent to SQL:

```
ALTER TABLE [<table_schema>.]<table_name>  REFERENCEABLE FOR <affected_schema>
```

which is currently not supported or available as a DDL statement.

Syntax

```
DBMS_DDL.ALTER_TABLE_REFERENCEABLE
   table_name       IN  VARCHAR2,
   table_schema     IN  DEFAULT  NULL,
   affected_schema  IN  DEFAULT  NULL);
```

Parameters

Table 61-5 ALTER_TABLE_REFERENCEABLE Procedure Parameters

Parameter	Description
table_name	Name of the table to be altered. Cannot be a synonym. Must not be NULL. Case sensitive.
table_schema	Name of the schema owning the table to be altered. If NULL then the current schema is used. Case sensitive.
affected_schema	Name of the schema affected by this alteration. If NULL then the current schema is used. Case sensitive.

Usage Notes

When you create an object table, it automatically becomes referenceable, unless you use the OID AS clause when creating the table. The OID AS clause makes it possible for you to create an object table and to assign to the new table the same EOID as another object table of the same type. After you create a new table using the OID AS clause, you end up with two object table with the same EOID; the new table is not referenceable, the original one is. All references that used to point to the objects in the original table still reference the same objects in the same original table.

If you execute this procedure on the new table, it makes the new table the referenceable table replacing the original one; thus, those references now point to the objects in the new table instead of the original table.

61.4.4 CREATE_WRAPPED Procedures

The procedure takes as input a single `CREATE OR REPLACE` statement that specifies creation of a PL/SQL package specification, package body, function, procedure, type specification or type body. It then generates a `CREATE OR REPLACE` statement with the PL/SQL source text obfuscated and executes the generated statement. In effect, this procedure bundles together the operations of wrapping the text and creating the PL/SQL unit.

> **See Also:**
>
> WRAP Functions

This procedure has 3 overloads. Each of the three functions provides better performance than using a combination of individual WRAP Functions and `DBMS_SQL.PARSE` (or `EXECUTE IMMEDIATE`) calls. The different functionality of each form of syntax is presented with the definition.

Syntax

Is a shortcut for `EXECUTE IMMEDIATE SYS.DBMS_DDL.WRAP`(*ddl*):

```
DBMS_DDL.CREATE_WRAPPED (
   ddl     VARCHAR2);
```

Is a shortcut for `DBMS_SQL.PARSE`(`cursor`, `SYS.DBMS_DDL.WRAP` (`input`, `lb`, `ub`)):

```
DBMS_DDL.CREATE_WRAPPED(
   ddl     DBMS_SQL.VARCHAR2A,
   lb      PLS_INTEGER,
   ub      PLS_INTEGER);
```

Is a shortcut for `DBMS_SQL.PARSE`(`cursor`, `SYS.DBMS_DDL.WRAP` (`input`, `lb`, `ub`)):

```
DBMS_DDL.CREATE_WRAPPED(
   ddl     DBMS_SQL.VARCHAR2S,
   lb      PLS_INTEGER,
   ub      PLS_INTEGER);
```

Parameters

Table 61-6 CREATE_WRAPPED Procedure Parameters

Parameter	Description
`ddl`	A `CREATE OR REPLACE` statement that specifies creation of a PL/SQL package specification, package body, function, procedure, type specification or type body
`lb`	Lower bound for indices in the string table that specify the `CREATE OR REPLACE` statement

Table 61-6 (Cont.) CREATE_WRAPPED Procedure Parameters

Parameter	Description
ub	Upper bound for indices in the string table that specify the CREATE OR REPLACE statement.

Usage Notes

- The CREATE OR REPLACE statement is executed with the privileges of the user invoking DBMS_DDL.CREATE_WRAPPED.
- Any PL/SQL code that attempts to call these interfaces should use the fully qualified package name SYS.DBMS_DDL to avoid the possibility that the name DBMS_DDL is captured by a locally-defined unit or by redefining the DBMS_DDL public synonym.
- Each invocation of any accepts only a single PL/SQL unit. By contrast, the PL/SQL wrap utility accepts a entire SQL*Plus file and obfuscates the PL/SQL units within the file leaving all other text as-is. These interfaces are intended to be used in conjunction with or as a replacement for PL/SQL's dynamic SQL interfaces (EXECUTE IMMEDIATE and DBMS_SQL.PARSE). Since these dynamic SQL interfaces only accept a single unit at a time (and do not understand the SQL*Plus "/" termination character), both the CREATE_WRAPPED Procedures and the WRAP Functions require input to be a single unit.

Exceptions

ORA-24230: If the input is not a CREATE OR REPLACE statement specifying a PL/SQL unit, exception DBMS_DDL.MALFORMED_WRAP_INPUT is raised.

Examples

```
DECLARE
    ddl VARCHAR2(32767);
BEGIN
    ddl := GENERATE_PACKAGE(...);
    SYS.DBMS_DDL.CREATE_WRAPPED(ddl); -- Instead of EXECUTE IMMEDIATE ddl
END;
```

61.4.5 IS_TRIGGER_FIRE_ONCE Function

This function returns TRUE if the specified DML or DDL trigger is set to fire once. Otherwise, it returns FALSE.

A fire once trigger fires in a user session but does not fire in the following cases:

- For changes made by a Streams apply process
- For changes made by executing one or more Streams apply errors using the EXECUTE_ERROR or EXECUTE_ALL_ERRORS procedure in the DBMS_APPLY_ADM package
- For changes made by a Logical Standby apply process

> **Note:**
>
> Only DML and DDL triggers can be fire once. All other types of triggers always fire.

> **See Also:**
>
> "SET_TRIGGER_FIRING_PROPERTY Procedures"

Syntax

```
DBMS_DDL.IS_TRIGGER_FIRE_ONCE
   trig_owner          IN  VARCHAR2,
   trig_name           IN  VARCHAR2)
 RETURN BOOLEAN;
```

Parameters

Table 61-7 IS_TRIGGER_FIRE_ONCE Function Parameters

Parameter	Description
trig_owner	Schema of trigger
trig_name	Name of trigger

61.4.6 SET_TRIGGER_FIRING_PROPERTY Procedures

This procedure sets the specified DML or DDL trigger's firing property whether or not the property is set for the trigger.

Use this procedure to control a DML or DDL trigger's firing property for changes:

- Applied by a Streams apply process
- Made by executing one or more Streams apply errors using the EXECUTE_ERROR or EXECUTE_ALL_ERRORS procedure in the DBMS_APPLY_ADM package.
- Applied by a Logical Standby apply process

Syntax

```
DBMS_DDL.SET_TRIGGER_FIRING_PROPERTY (
   trig_owner          IN  VARCHAR2,
   trig_name           IN  VARCHAR2,
   fire_once           IN  BOOLEAN);

DBMS_DDL.SET_TRIGGER_FIRING_PROPERTY (
   trig_owner          IN  VARCHAR2,
   trig_name           IN  VARCHAR2,
   property            IN INTEGER,
   setting             IN BOOLEAN);
```

Parameters

Table 61-8 SET_TRIGGER_FIRING_PROPERTY Procedure Parameters

Parameter	Description
trig_owner	Schema of the trigger to set
trig_name	Name of the trigger to set
fire_once	• If TRUE, the trigger is set to fire once. By default, the fire_once parameter is set to TRUE for DML and DDL triggers. • If FALSE, the trigger is set to always fire unless apply_server_only property is set to TRUE, which overrides fire_once property setting.
property	• DBMS_DDL.fire_once to set the fire_once property of the trigger • DBMS_DDL.apply_server_only to indicate whether trigger fires only in the context of SQL apply processes maintaining a logical standby database or Streams apply processes
setting	Value of property being set

Usage Notes

DML triggers created on a table have their fire-once property set to TRUE. In this case, the triggers only fire when the table is modified by an user process, and they are automatically disabled inside Oracle processes maintaining either a logical standby database (SQL Apply) or Oracle processes doing replication (Streams Apply) processes, and thus do not fire when a SQL Apply or a Streams Apply process modifies the table. There are two ways for a user to fire a trigger as a result of SQL Apply or a Streams Apply process making a change to a maintained table: (a) setting the fire-once property of a trigger to FALSE, which allows it fire both in the context of a user process or a SQL or Streams Apply process, or (b) by setting the apply-server-only property to TRUE and thus making the trigger fire only in the context of a SQL Apply or a Streams Apply process and not in the context of a user process.

- FIRE_ONCE=TRUE, APPLY_SERVER_ONLY=FALSE

  This is the default property setting for a DML trigger. The trigger only fires when user process modifies the base table.

- FIRE_ONCE=TRUE or FALSE, APPLY_SERVER_ONLY=TRUE

  The trigger only fires when SQL Apply or Streams Apply process modifies the base table. The trigger does not fire when a user process modifies the base table.Thus the apply-server-only property overrides the fire-once property of a trigger.

Note:

- If you dequeue an error transaction from the error queue and execute it without using the DBMS_APPLY_ADM package, then relevant changes resulting from this execution cause a trigger to fire, regardless of the trigger firing property.
- Only DML and DDL triggers can be fire once. All other types of triggers always fire.

61.4.7 WRAP Functions

This function takes as input a single CREATE OR REPLACE statement that specifies creation of a PL/SQL package specification, package body, function, procedure, type specification or type body and returns a CREATE OR REPLACE statement where the text of the PL/SQL unit has been obfuscated.

The function has 3 overloads to allow for the different ways in which DDL statements can be generated dynamically and presented to DBMS_SQL or EXECUTE IMMEDIATE. The different functionality of each form of syntax is presented with the definition.

See Also:

CREATE_WRAPPED Procedures

Syntax

Provides basic functionality:

```
DBMS_DDL.WRAP(
   ddl      VARCHAR2)
  RETURN VARCHAR2;
```

Provides the same functionality as the first form, but allows for larger inputs. This function is intended to be used with the PARSE Procedures in the DBMS_SQL package and its argument list follows the convention of DBMS_SQL.PARSE:

```
DBMS_DDL.WRAP(
   ddl      DBMS_SQL.VARCHAR2S,
   lb       PLS_INTEGER,
   ub       PLS_INTEGER)
  RETURN DBMS_SQL.VARCHAR2S;
```

Provides the same functionality as the second form and is provided for compatibility with multiple forms of the PARSE Procedures in the DBMS_SQL package:

```
DBMS_DDL.WRAP(
   ddl      DBMS_SQL.VARCHAR2A,
   lb       PLS_INTEGER,
   ub       PLS_INTEGER)
  RETURN DBMS_SQL.VARCHAR2A;
```

Parameters

Table 61-9 WRAP Function Parameters

Parameter	Description
ddl	A CREATE OR REPLACE statement that specifies creation of a PL/SQL package specification, package body, function, procedure, type specification or type body
lb	Lower bound for indices in the string table that specify the CREATE OR REPLACE statement
ub	Upper bound for indices in the string table that specify the CREATE OR REPLACE statement.

Return Values

A CREATE OR REPLACE statement with the text obfuscated. In the case of the second and third form, the return value is a table of strings that need to be concatenated in order to construct the CREATE OR REPLACE string containing obfuscated source text.

Usage Notes

- Any PL/SQL code that attempts to call these interfaces should use the fully qualified package name SYS.DBMS_DDL to avoid the possibility that the name DBMS_DDL is captured by a locally-defined unit or by redefining the DBMS_DDL public synonym.
- Each invocation of any accepts only a single PL/SQL unit. By contrast, the PL/SQL wrap utility accepts a full SQL file and obfuscates the PL/SQL units within the file leaving all other text as-is. These interfaces are intended to be used in conjunction with or as a replacement for PL/SQL's dynamic SQL interfaces (EXECUTE IMMEDIATE and DBMS_SQL.PARSE). Since these dynamic SQL interfaces only accept a single unit at a time (and do not understand the SQL*Plus "/" termination character), both the CREATE_WRAPPED Procedures and the WRAP Functions require input to be a single unit.

Exceptions

ORA-24230: If the input is not a CREATE OR REPLACE statement specifying a PL/SQL unit, exception DBMS_DDL.MALFORMED_WRAP_INPUT is raised.

Examples

```
DECLARE
   ddl VARCHAR2(32767);
BEGIN
   ddl := GENERATE_PACKAGE(...);
EXECUTE IMMEDIATE SYS.DBMS_DDL.WRAP(ddl); -- Instead of EXECUTE IMMEDIATE ddl
END;
```

62
DBMS_DEBUG

DBMS_DEBUG is deprecated. Use DBMS_DEBUG_JDWP instead.

See DBMS_DEBUG_JDWP for more information.

DBMS_DEBUG is a PL/SQL interface to the PL/SQL debugger layer, Probe, in the Oracle server.

This package is primarily intended to implement server-side debuggers and it provides a way to debug server-side PL/SQL program units.

> **Note:**
>
> The term *program unit* refers to a PL/SQL program of any type (procedure, function, package, package body, trigger, anonymous block, object type, or object type body).

This chapter contains the following topics:

- Overview
- Constants
- Variables
- Exceptions
- Operational Notes
- Data Structures
- Summary of DBMS_DEBUG Subprograms

62.1 DBMS_DEBUG Overview

To debug server-side code, you must have two database sessions: one session to run the code in debug mode (the target session), and a second session to supervise the target session (the debug session).

The target session becomes available for debugging by making initializing calls with DBMS_DEBUG. This marks the session so that the PL/SQL interpreter runs in debug mode and generates debug events. As debug events are generated, they are posted from the session. In most cases, debug events require return notification: the interpreter pauses awaiting a reply.

Meanwhile, the debug session must also initialize itself using DBMS_DEBUG: This tells it which target session to supervise. The debug session may then call entry points in DBMS_DEBUG to read events that were posted from the target session and to communicate with the target session.

The following subprograms are run in the target session (the session that is to be debugged):

- SYNCHRONIZE Function
- DEBUG_ON Procedure
- DEBUG_OFF Procedure

DBMS_DEBUG does not provide an interface to the PL/SQL compiler, but it does depend on debug information optionally generated by the compiler. Without debug information, it is not possible to examine or modify the values of parameters or variables.

62.2 DBMS_DEBUG Constants

A breakpoint status may have the following value: breakpoint_status_unused—breakpoint is not in use.

Otherwise, the status is a mask of the following values:

- breakpoint_status_active—a line breakpoint
- breakpoint_status_disabled—breakpoint is currently disabled
- breakpoint_status_remote—a shadow breakpoint (a local representation of a remote breakpoint)

62.3 DBMS_DEBUG Variables

The DBMS_DEBUG uses the variables shown in the following table.

Table 62-1 DBMS_DEBUG Variables

Variable	Description
default_timeout	The timeout value (used by both sessions).The smallest possible timeout is 1 second. If this value is set to 0, then a large value (3600) is used.

62.4 DBMS_DEBUG Exceptions

These values are returned by the various functions called in the debug session (SYNCHRONIZE, CONTINUE, SET_BREAKPOINT, and so on). If PL/SQL exceptions worked across client/server and server/server boundaries, then these would all be exceptions rather than error codes.

Table 62-2 DBMS_DEBUG Exceptions

Status	Description
success	Normal termination

Statuses returned by GET_VALUE and SET_VALUE:

Table 62-3 DBMS_DEBUG Exceptions Returned by GET_VALUE and SET_VALUE

Status	Description
error_bogus_frame	No such entrypoint on the stack
error_no_debug_info	Program was compiled without debug symbols
error_no_such_object	No such variable or parameter
error_unknown_type	Debug information is unreadable
error_indexed_table	Returned by GET_VALUE if the object is a table, but no index was provided
error_illegal_index	No such element exists in the collection
error_nullcollection	Table is atomically NULL
error_nullvalue	Value is NULL

Statuses returned by SET_VALUE:

Table 62-4 DBMS_DEBUG Exceptions Returned by SET_VALUE

Status	Description
error_illegal_value	Constraint violation
error_illegal_null	Constraint violation
error_value_malformed	Unable to decipher the given value
error_other	Some other error
error_name_incomplete	Name did not resolve to a scalar

Statuses returned by the breakpoint functions:

Table 62-5 Statuses Returned by the Breakpoint Functions

Status	Description
error_no_such_breakpt	No such breakpoint
error_idle_breakpt	Cannot enable or disable an unused breakpoint
error_bad_handle	Unable to set breakpoint in given program (nonexistent or security violation)

General error codes (returned by many of the DBMS_DEBUG subprograms):

Table 62-6 DBMS_DEBUG Subprograms Error Codes

Status	Description
error_unimplemented	Functionality is not yet implemented
error_deferred	No program running; operation deferred
error_exception	An exception was raised in the DBMS_DEBUG or Probe packages on the server
error_communication	Some error other than a timeout occurred

Table 62-6 (Cont.) DBMS_DEBUG Subprograms Error Codes

Status	Description
error_timeout	Timout occurred

Table 62-7 illegal_init Exceptions

Exception	Description
illegal_init	DEBUG_ON was called prior to INITIALIZE

The following exceptions are raised by procedure SELF_CHECK:

Table 62-8 SELF_CHECK Procedure Exceptions

Exception	Description
pipe_creation_failure	Could not create a pipe
pipe_send_failure	Could not write data to the pipe
pipe_receive_failure	Could not read data from the pipe
pipe_datatype_mismatch	Datatype in the pipe was wrong
pipe_data_error	Data got garbled in the pipe

62.5 DBMS_DEBUG Operational Notes

There are two ways to ensure that debug information is generated: through a session switch, or through individual recompilation.

To set the session switch, enter the following statement:

```
ALTER SESSION SET PLSQL_DEBUG = true;
```

This instructs the compiler to generate debug information for the remainder of the session. It does not recompile any existing PL/SQL.

To generate debug information for existing PL/SQL code, use one of the following statements (the second recompiles a package or type body):

```
ALTER [PROCEDURE | FUNCTION | PACKAGE | TRIGGER | TYPE] <name> COMPILE DEBUG;
ALTER [PACKAGE | TYPE] <name> COMPILE DEBUG BODY;
```

Figure 62-1 and Figure 62-2 illustrate the flow of operations in the session to be debugged and in the debugging session.

platform: pc

Control of the Interpreter

The interpreter pauses execution at the following times:

1. At startup of the interpreter so any deferred breakpoints may be installed prior to execution.
2. At any line containing an enabled breakpoint.
3. At any line where an *interesting* event occurs. The set of interesting events is specified by the flags passed to `DBMS_DEBUG.CONTINUE` in the `breakflags` parameter.

Session Termination

There is no event for session termination. Therefore, it is the responsibility of the debug session to check and make sure that the target session has not ended. A call to `DBMS_DEBUG.SYNCHRONIZE` after the target session has ended causes the debug session to hang until it times out.

Deferred Operations

The diagram suggests that it is possible to set breakpoints prior to having a target session. This is true. In this case, Probe caches the breakpoint request and transmits it to the target session at first synchronization. However, if a breakpoint request is deferred in this fashion, then:

- `SET_BREAKPOINT` does not set the breakpoint number (it can be obtained later from `SHOW_BREAKPOINTS` if necessary).
- `SET_BREAKPOINT` does not validate the breakpoint request. If the requested source line does not exist, then an error silently occurs at synchronization, and no breakpoint is set.

Diagnostic Output

To debug Probe, there are *diagnostics* parameters to some of the calls in `DBMS_DEBUG`. These parameters specify whether to place diagnostic output in the RDBMS tracefile. If output to the RDBMS tracefile is disabled, these parameters have no effect.

Common Debug Session Sections

- Common Section
- Target Session
- Debug Session Section

Common Section

The following subprograms may be called in either the target or the debug session:

- PROBE_VERSION Procedure
- SELF_CHECK Procedure
- SET_TIMEOUT Function

Target Session

The following subprograms may be called only in the target session:

- INITIALIZE Function
- DEBUG_ON Procedure
- SET_TIMEOUT_BEHAVIOUR Procedure
- GET_TIMEOUT_BEHAVIOUR Function

Debug Session Section

The following subprograms should be run in the debug session only:

- ATTACH_SESSION Procedure
- SYNCHRONIZE Function

- SHOW_FRAME_SOURCE Procedure
- SHOW_SOURCE Procedures
- GET_MORE_SOURCE Procedure
- PRINT_BACKTRACE Procedure
- CONTINUE Function
- SET_BREAKPOINT Function
- DELETE_BREAKPOINT Function
- SET_OER_BREAKPOINT Function
- DELETE_OER_BREAKPOINT Function
- ENABLE_BREAKPOINT Function
- DISABLE_BREAKPOINT Function
- SHOW_BREAKPOINTS Procedures
- SET_VALUE Functionn
- GET_VALUE Function
- TARGET_PROGRAM_RUNNING Procedure
- DETACH_SESSION Procedure
- GET_RUNTIME_INFO Function
- PRINT_INSTANTIATIONS Procedure
- PING Procedure
- GET_LINE_MAP Function
- GET_RUNTIME_INFO Function
- GET_INDEXES Function
- EXECUTE Procedure

OER Breakpoints

Exceptions that are declared in PL/SQL programs are known as user-defined exceptions. In addition, there are Oracle Errors (OERs) that are returned from the Oracle kernel. To tie the two mechanisms together, PL/SQL provides the `exception_init` pragma that turns a user-defined exception into an OER, so that a PL/SQL handler may be used for it, and so that the PL/SQL engine can return OERs to the Oracle kernel. As of the current release, the only information available about an OER is its number. If two user-defined exceptions are exception_init'd to the same OER, they are indistinguishable.

Namespaces

Program units on the server reside in different namespaces. When setting a breakpoint, specify the desired namespace.

1. `Namespace_cursor` contains cursors (anonymous blocks).
2. `Namespace_pgkspec_or_toplevel` contains:
   - Package specifications.

- Procedures and functions that are not nested inside other packages, procedures, or functions.
- Object types.

3. `Namespace_pkg_body` contains package bodies and type bodies.
4. `Namespace_trigger` contains triggers.

Libunit Types

These values are used to disambiguate among objects in a given namespace. These constants are used in `PROGRAM_INFO` when Probe is giving a stack backtrace.

- `LibunitType_cursor`
- `LibunitType_procedure`
- `LibunitType_function`
- `LibunitType_package`
- `LibunitType_package_body`
- `LibunitType_trigger`
- `LibunitType_Unknown`

Breakflags

These are values to use for the `breakflags` parameter to `CONTINUE`, in order to tell Probe what events are of interest to the client. These flags may be combined.

Value	Description
`break_next_line`	Break at next source line (step over calls)
`break_any_call`	Break at next source line (step into calls)
`break_any_return`	Break after returning from current entrypoint (skip over any entrypoints called from the current routine)
`break_return`	Break the next time an entrypoint gets ready to return. (This includes entrypoints called from the current one. If interpreter is running `Proc1`, which calls `Proc2`, then `break_return` stops at the end of `Proc2`.)
`break_exception`	Break when an exception is raised
`break_handler`	Break when an exception handler is executed
`abort_execution`	Stop execution and force an 'exit' event as soon as `DBMS_DEBUG.CONTINUE` is called.

Information Flags

These are flags which may be passed as the `info_requested` parameter to `SYNCHRONIZE`, `CONTINUE`, and `GET_RUNTIME_INFO`.

Flag	Description
`info_getStackDepth`	Get the current depth of the stack
`info_getBreakpoint`	Get the breakpoint number
`info_getLineinfo`	Get program unit information

Reasons for Suspension

After `CONTINUE` is run, the program either runs to completion or breaks on some line.

Reason	Description
`reason_none`	-
`reason_interpreter_starting`	Interpreter is starting
`reason_breakpoint`	Hit a breakpoint
`reason_enter`	Procedure entry
`reason_return`	Procedure is about to return
`reason_finish`	Procedure is finished
`reason_line`	Reached a new line
`reason_interrupt`	An interrupt occurred
`reason_exception`	An exception was raised
`reason_exit`	Interpreter is exiting (old form)
`reason_knl_exit`	Kernel is exiting
`reason_handler`	Start exception-handler
`reason_timeout`	A timeout occurred
`reason_instantiate`	Instantiation block
`reason_abort`	Interpreter is aborting

62.6 DBMS_DEBUG Data Structures

The `DBMS_DEBUG` package defines `RECORD` types and `TABLE` types.

RECORD Types

- BREAKPOINT_INFO Record Type
- PROGRAM_INFO Record Type
- RUNTIME_INFO Record Type

TABLE Types

- BACKTRACE_TABLE Table Type
- BREAKPOINT_TABLE Table Type
- INDEX_TABLE Table Type
- VC2_TABLE Table Type

62.6.1 BREAKPOINT_INFO Record Type

This type gives information about a breakpoint, such as its current status and the program unit in which it was placed.

Syntax

```
TYPE breakpoint_info IS RECORD (
   name        VARCHAR2(30),
   owner       VARCHAR2(30),
   dblink      VARCHAR2(30),
   line#       BINARY_INTEGER,
   libunittype BINARY_INTEGER,
   status      BINARY_INTEGER);
```

Fields

Table 62-9 BREAKPOINT_INFO Fields

Field	Description
`name`	Name of the program unit
`owner`	Owner of the program unit
`dblink`	Database link, if remote
`line#`	Line number
`libunittype`	`NULL`, unless this is a nested procedure or function
`status`	See Constants for values of `breakpoint_status_*`

62.6.2 PROGRAM_INFO Record Type

The `PROGRAM_INFO` record type of the `DBMS_DEBG` package specifies a program location. It is a line number in a program unit.

This is used for stack backtraces and for setting and examining breakpoints. The read-only fields are currently ignored by Probe for breakpoint operations. They are set by Probe only for stack backtraces.

Syntax

```
TYPE program_info IS RECORD(
    -- The following fields are used when setting a breakpoint
    namespace        BINARY_INTEGER,
    name             VARCHAR2(30),
    owner            VARCHAR2(30),
    dblink           VARCHAR2(30),
    line#            BINARY_INTEGER,
    -- Read-only fields (set by Probe when doing a stack backtrace)
    libunittype      BINARY_INTEGER,
    entrypointname   VARCHAR2(30));
```

Fields

Table 62-10 PROGRAM_INFO Fields

Field	Description
`namespace`	See DBMS_DEBUG Operational Notes for more information about namespaces.
`name`	Name of the program unit
`owner`	Owner of the program unit
`dblink`	Database link, if remote
`line#`	Line number
`libunittype`	A `read-only field, NULL`, unless this is a nested procedure or function
`entrypointname`	A read-only field, to disambiguate among objects that share the same namespace (for example, procedure and package specifications). See DBMS_DEBUG Operational Notes for more information about the libunit types.

62.6.3 RUNTIME_INFO Record Type

This type gives context information about the running program.

Syntax

```
TYPE runtime_info IS RECORD(
    line#            BINARY_INTEGER,
    terminated       binary_integer,
    breakpoint       binary_integer,
    stackdepth       BINARY_INTEGER,
    interpreterdepth BINARY_INTEGER,
    reason           BINARY_INTEGER,
    program          program_info);
```

Fields

Table 62-11 RUNTIME_INFO Fields

Field	Description
`line#`	Duplicate of `program.line#`
`terminated`	Whether the program has terminated
`breakpoint`	Breakpoint number
`stackdepth`	Number of frames on the stack
`interpreterdepth`	[A reserved field]
`reason`	Reason for suspension
`program`	Source location

62.6.4 BACKTRACE_TABLE Table Type

This type is used by PRINT_BACKTRACE.

Syntax

```
TYPE backtrace_table IS TABLE OF program_info INDEX BY BINARY_INTEGER;
```

62.6.5 BREAKPOINT_TABLE Table Type

This type is used by SHOW_BREAKPOINTS.

Syntax

```
TYPE breakpoint_table IS TABLE OF breakpoint_info INDEX BY BINARY_INTEGER;
```

62.6.6 INDEX_TABLE Table Type

This type is used by GET_INDEXES to return the available indexes for an indexed table.

Syntax

```
TYPE index_table IS table of BINARY_INTEGER INDEX BY BINARY_INTEGER;
```

62.6.7 VC2_TABLE Table Type

This type is used by SHOW_SOURCE.

Syntax

```
TYPE vc2_table IS TABLE OF VARCHAR2(90) INDEX BY BINARY_INTEGER;
```

62.7 Summary of DBMS_DEBUG Subprograms

This table lists the DBMS_DEBUG subprograms in alphabetical order and briefly describes them.

Table 62-12 DBMS_DEBUG Package Subprograms

Subprogram	Description
ATTACH_SESSION Procedure	Notifies the debug session about the target debugID
CONTINUE Function	Continues execution of the target program
DEBUG_OFF Procedure	Turns debug-mode off
DEBUG_ON Procedure	Turns debug-mode on
DELETE_BREAKPOINT Function	Deletes a breakpoint
DELETE_OER_BREAKPOINT Function	Deletes an OER breakpoint
DETACH_SESSION Procedure	Stops debugging the target program

Table 62-12 (Cont.) DBMS_DEBUG Package Subprograms

Subprogram	Description
DISABLE_BREAKPOINT Function	Disables a breakpoint
ENABLE_BREAKPOINT Function	Activates an existing breakpoint
EXECUTE Procedure	Executes SQL or PL/SQL in the target session
GET_INDEXES Function	Returns the set of indexes for an indexed table
GET_MORE_SOURCE Procedure	Provides additional source in the event of buffer overflow when using SHOW_SOURCE
GET_LINE_MAP Function	Returns information about line numbers in a program unit
GET_RUNTIME_INFO Function	Returns information about the current program
GET_TIMEOUT_BEHAVIOUR Function	Returns the current timeout behavior
GET_VALUE Function	Gets a value from the currently-running program
INITIALIZE Function	Sets debugID in target session
PING Procedure	Pings the target session to prevent it from timing out
PRINT_BACKTRACE Procedure	Prints a stack backtrace
PRINT_INSTANTIATIONS Procedure	Prints a stack backtrace
PROBE_VERSION Procedure	Returns the version number of `DBMS_DEBUG` on the server
SELF_CHECK Procedure	Performs an internal consistency check
SET_BREAKPOINT Function	Sets a breakpoint in a program unit
SET_OER_BREAKPOINT Function	Sets an OER breakpoint
SET_TIMEOUT Function	Sets the timeout value
SET_TIMEOUT_BEHAVIOUR Procedure	Tells Probe what to do with the target session when a timeout occurs
SET_VALUE Function	Sets a value in the currently-running program
SHOW_BREAKPOINTS Procedures	Returns a listing of the current breakpoints
SHOW_FRAME_SOURCE Procedure	Fetches the frame source
SHOW_SOURCE Procedures	Fetches program source
SYNCHRONIZE Function	Waits for program to start running
TARGET_PROGRAM_RUNNING Procedure	Returns `TRUE` if the target session is currently executing a stored procedure, or `FALSE` if it is not

62.7.1 ATTACH_SESSION Procedure

This procedure notifies the debug session about the target program.

Syntax

```
DBMS_DEBUG.ATTACH_SESSION (
   debug_session_id  IN VARCHAR2,
   diagnostics       IN BINARY_INTEGER := 0);
```

Parameters

Table 62-13 ATTACH_SESSION Procedure Parameters

Parameter	Description
`debug_session_id`	Debug ID from a call to `INITIALIZE` in target session
`diagnostics`	Generate diagnostic output if nonzero

62.7.2 CONTINUE Function

This function passes the given breakflags (a mask of the events that are of interest) to Probe in the target process. It tells Probe to continue execution of the target process, and it waits until the target process runs to completion or signals an event.

If `info_requested` is not `NULL`, then calls `GET_RUNTIME_INFO`.

Syntax

```
DBMS_DEBUG.CONTINUE (
   run_info       IN OUT runtime_info,
   breakflags     IN     BINARY_INTEGER,
   info_requested IN     BINARY_INTEGER := NULL)
  RETURN BINARY_INTEGER;
```

Parameters

Table 62-14 CONTINUE Function Parameters

Parameter	Description
`run_info`	Information about the state of the program
`breakflags`	Mask of events that are of interest (see the discussion about break flags under DBMS_DEBUG Operational Notes)
`info_requested`	Which information should be returned in `run_info` when the program stops (see the discussion of information flags under DBMS_DEBUG Operational Notes)

Return Values

Table 62-15 CONTINUE Function Return Values

Return	Description
`success`	
`error_timeout`	Timed out before the program started running
`error_communication`	Other communication error

62.7.3 DEBUG_OFF Procedure

This procedure notifies the target session that debugging should no longer take place in that session. It is not necessary to call this function before ending the session.

> **WARNING:**
>
> There must be a debug session waiting if immediate is `TRUE`.

Syntax

```
DBMS_DEBUG.DEBUG_OFF;
```

Usage Notes

The server does not handle this entrypoint specially. Therefore, it attempts to debug this entrypoint.

62.7.4 DEBUG_ON Procedure

This procedure marks the target session so that all PL/SQL is run in debug mode. This must be done before any debugging can take place.

Syntax

```
DBMS_DEBUG.DEBUG_ON (
   no_client_side_plsql_engine BOOLEAN := TRUE,
   immediate                   BOOLEAN := FALSE);
```

Parameters

Table 62-16 DEBUG_ON Procedure Parameters

Parameter	Description
`no_client_side_plsql_engine`	Should be left to its default value unless the debugging session is taking place from a client-side PL/SQL engine
`immediate`	If this is `TRUE`, then the interpreter immediately switches itself into debug-mode, instead of continuing in regular mode for the duration of the call.

62.7.5 DELETE_BREAKPOINT Function

This function deletes a breakpoint.

Syntax

```
DBMS_DEBUG.DELETE_BREAKPOINT (
   breakpoint IN BINARY_INTEGER)
  RETURN BINARY_INTEGER;
```

Parameters

Table 62-17 DELETE_BREAKPOINT Function Parameters

Parameter	Description
`breakpoint`	Breakpoint number from a previous call to `SET_BREAKPOINT`

Return Values

Table 62-18 DELETE_BREAKPOINT Function Return Values

Return	Description
`success`	
`error_no_such_breakpt`	No such breakpoint exists
`error_idle_breakpt`	Cannot delete an unused breakpoint
`error_stale_breakpt`	The program unit was redefined since the breakpoint was set

62.7.6 DELETE_OER_BREAKPOINT Function

This function deletes an OER breakpoint.

Syntax

```
DBMS_DEBUG.DELETE_OER_BREAKPOINT (
   oer  IN PLS_INTEGER)
RETURN PLS_INTEGER;
```

Parameters

Table 62-19 DELETE_OER_BREAKPOINT Function Parameters

Parameter	Description
`oer`	The OER (positive 4-byte number) to delete

62.7.7 DETACH_SESSION Procedure

This procedure stops debugging the target program.

This procedure may be called at any time, but it does not notify the target session that the debug session is detaching itself, and it does not terminate execution of the target session. Therefore, care should be taken to ensure that the target session does not hang itself.

Syntax

```
DBMS_DEBUG.DETACH_SESSION;
```

62.7.8 DISABLE_BREAKPOINT Function

This function makes an existing breakpoint inactive but leaves it in place.

Syntax

```
DBMS_DEBUG.DISABLE_BREAKPOINT (
   breakpoint IN BINARY_INTEGER)
  RETURN BINARY_INTEGER;
```

Parameters

Table 62-20 DISABLE_BREAKPOINT Function Parameters

Parameter	Description
breakpoint	Breakpoint number from a previous call to SET_BREAKPOINT

Return Values

Table 62-21 DISABLE_BREAKPOINT Function Return Values

Returns	Description
success	
error_no_such_breakpt	No such breakpoint exists
error_idle_breakpt	Cannot disable an unused breakpoint

62.7.9 ENABLE_BREAKPOINT Function

This function is the reverse of disabling. This enables a previously disabled breakpoint.

Syntax

```
DBMS_DEBUG.ENABLE_BREAKPOINT (
   breakpoint IN BINARY_INTEGER)
  RETURN BINARY_INTEGER;
```

Parameters

Table 62-22 ENABLE_BREAKPOINT Function Parameters

Parameter	Description
`breakpoint`	Breakpoint number from a previous call to `SET_BREAKPOINT`

Return Values

Table 62-23 ENABLE_BREAKPOINT Function Return Values

Return	Description
`success`	Success
`error_no_such_breakpt`	No such breakpoint exists
`error_idle_breakpt`	Cannot enable an unused breakpoint

62.7.10 EXECUTE Procedure

This procedure executes SQL or PL/SQL code in the target session. The target session is assumed to be waiting at a breakpoint (or other event). The call to `DBMS_DEBUG.EXECUTE` occurs in the debug session, which then asks the target session to execute the code.

Syntax

```
DBMS_DEBUG.EXECUTE (
   what         IN VARCHAR2,
   frame#       IN BINARY_INTEGER,
   bind_results IN BINARY_INTEGER,
   results      IN OUT NOCOPY dbms_debug_vc2coll,
   errm         IN OUT NOCOPY VARCHAR2);
```

Parameters

Table 62-24 EXECUTE Procedure Parameters

Parameter	Description
`what`	SQL or PL/SQL source to execute
`frame#`	The context in which to execute the code. Only -1 (global context) is supported at this time.
`bind_results`	Whether the source wants to bind to `results` in order to return values from the target session: 0 = No 1 = Yes
`results`	Collection in which to place results, if `bind_results` is not 0
`errm`	Error message, if an error occurred; otherwise, `NULL`

Examples

Example 1

This example executes a SQL statement. It returns no results.

```
DECLARE
   coll sys.dbms_debug_vc2coll; -- results (unused)
   errm VARCHAR2(100);
BEGIN
   dbms_debug.execute('insert into emp(ename,empno,deptno) ' ||
                      'values(''LJE'', 1, 1)',
                      -1, 0, coll, errm);
END;
```

Example 2

This example executes a PL/SQL block, and it returns no results. The block is an autonomous transaction, which means that the value inserted into the table becomes visible in the debug session.

```
DECLARE
   coll sys.dbms_debug_vc2coll;
   errm VARCHAR2(100);
BEGIN
   dbms_debug.execute(
       'DECLARE PRAGMA autonomous_transaction; ' ||
       'BEGIN ' ||
       '   insert into emp(ename, empno, deptno) ' ||
       '   values(''LJE'', 1, 1); ' ||
       ' COMMIT; ' ||
       'END;',
       -1, 0, coll, errm);
END;
```

Example 3

This example executes a PL/SQL block, and it returns some results.

```
DECLARE
   coll sys.dbms_debug_vc2coll;
   errm VARCHAR2(100);
BEGIN
   dbms_debug.execute(
      'DECLARE ' ||
      '   pp SYS.dbms_debug_vc2coll := SYS.dbms_debug_vc2coll(); ' ||
      '   x  PLS_INTEGER; ' ||
      '   i  PLS_INTEGER := 1; ' ||
      'BEGIN ' ||
      '   SELECT COUNT(*) INTO x FROM emp; ' ||
      '   pp.EXTEND(x * 6); ' ||
      '   FOR c IN (SELECT * FROM emp) LOOP ' ||
      '      pp(i) := ''Ename: '' || c.ename; i := i+1; ' ||
      '      pp(i) := ''Empno: '' || c.empno; i := i+1; ' ||
      '      pp(i) := ''Job:   '' || c.job;   i := i+1; ' ||
      '      pp(i) := ''Mgr:   '' || c.mgr;   i := i+1; ' ||
      '      pp(i) := ''Sal:   '' || c.sal;   i := i+1; ' ||
      '      pp(i) := null;                   i := i+1; ' ||
      '   END LOOP; ' ||
      '   :1 := pp;' ||
      'END;',
```

```
      -1, 1, coll, errm);
   each := coll.FIRST;
   WHILE (each IS NOT NULL) LOOP
      dosomething(coll(each));
      each := coll.NEXT(each);
   END LOOP;
END;
```

62.7.11 GET_INDEXES Function

Given a name of a variable or parameter, this function returns the set of its indexes, if it is an indexed table. An error is returned if it is not an indexed table.

Syntax

```
DBMS_DEBUG.GET_INDEXES (
   varname   IN  VARCHAR2,
   frame#    IN  BINARY_INTEGER,
   handle    IN  program_info,
   entries   OUT index_table)
RETURN BINARY_INTEGER;
```

Parameters

Table 62-25 GET_INDEXES Function Parameters

Parameter	Description
`varname`	Name of the variable to get index information about
`frame#`	Number of frame in which the variable or parameter resides; `NULL` for a package variable
`handle`	Package description, if object is a package variable
`entries`	1-based table of the indexes: if non-`NULL`, then `entries`(1) contains the first index of the table, `entries`(2) contains the second index, and so on.

Return Values

Table 62-26 GET_INDEXES Function Return Values

Return	Description
`error_no_such_object`	One of the following: - The package does not exist - The package is not instantiated - The user does not have privileges to debug the package - The object does not exist in the package

62.7.12 GET_MORE_SOURCE Procedure

When the source does not fit in the buffer provided by the SHOW_SOURCE Procedure version which produced a formatted buffer, this procedure provides additional source.

Syntax

```
DBMS_DEBUG.GET_MORE_SOURCE (
   buffer          IN OUT VARCHAR2,
   buflen          IN BINARY_INTEGER,
   piece#          IN BINARY_INTEGER);
```

Parameters

Table 62-27 GET_MORE_SOURCE Procedure Parameters

Parameter	Description
buffer	The buffer
buflen	The length of the buffer
piece#	A value between 2 and the value returned in the parameter pieces from the call to the relevant version of the SHOW_SOURCE Procedures

Usage Notes

This procedure should be called only after the version of SHOW_SOURCE that returns a formatted buffer.

Related Topics

- SHOW_SOURCE Procedures
  The procedure gets the source code. There are two overloaded SHOW_SOURCE procedures.

62.7.13 GET_LINE_MAP Function

This function finds line and entrypoint information about a program so that a debugger can determine the source lines at which it is possible to place breakpoints.

Syntax

```
DBMS_DEBUG.GET_LINE_MAP (
   program               IN   program_info,
   maxline               OUT  BINARY_INTEGER,
   number_of_entry_points OUT  BINARY_INTEGER,
   linemap               OUT  RAW)
  RETURN BINARY_INTEGER;
```

Parameters

Table 62-28 GET_LINE_MAP Function Parameters

Parameter	Description
`program`	A top-level program unit (procedure / package / function / package body, and so on). Its `Namespace`, `Name`, and `Owner` fields must be initialized, the remaining fields are ignored.
`maxline`	The largest source code line number in 'program'
`number_of_entry_points`	The number of subprograms in 'program'
`linemap`	A bitmap representing the executable lines of 'program'. If line number N is executable, bit number N MOD 8 will be set to 1 at linemap position N / 8. The length of returned linemap is either `maxline` divided by 8 (plus one if `maxline` MOD 8 is not zero) or 32767 in the unlikely case of `maxline` being larger than 32767 * 8.

Return Values

Table 62-29 GET_LINE_MAP Function Return Values

Return	Description
`success`	A successful completion
`error_no_debug_info`	The program unit exists, but has no debug info
`error_bad_handle`	No such program unit exists

62.7.14 GET_RUNTIME_INFO Function

This function returns information about the current program. It is only needed if the `info_requested` parameter to `SYNCHRONIZE` or `CONTINUE` was set to `0`.

> **Note:**
>
> This is currently only used by client-side PL/SQL.

Syntax

```
DBMS_DEBUG.GET_RUNTIME_INFO (
   info_requested  IN  BINARY_INTEGER,
   run_info        OUT runtime_info)
  RETURN BINARY_INTEGER;
```

Parameters

Table 62-30 GET_RUNTIME_INFO Function Parameters

Parameter	Description
`info_requested`	Which information should be returned in `run_info` when the program stops (see DBMS_DEBUG Operational Notes for information about information flags)
`run_info`	Information about the state of the program

62.7.15 GET_TIMEOUT_BEHAVIOUR Function

This procedure returns the current timeout behavior. This call is made in the target session.

Syntax

```
DBMS_DEBUG.GET_TIMEOUT_BEHAVIOUR
 RETURN BINARY_INTEGER;
```

Parameters

Table 62-31 GET_TIMEOUT_BEHAVIOUR Function Parameters

Parameter	Description
`oer`	The OER (a 4-byte positive number)

Return Values

Table 62-32 GET_TIMEOUT_BEHAVIOUR Function Return Values

Return	Description
`success`	A successful completion

Information Flags

```
info_getOerInfo CONSTANT PLS_INTEGER:= 32;
```

Usage Notes

Less functionality is supported on OER breakpoints than on code breakpoints. In particular, note that:

- No "breakpoint number" is returned - the number of the OER is used instead. Thus it is impossible to set duplicate breakpoints on a given OER (it is a no-op).
- It is not possible to disable an OER breakpoint (although clients are free to simulate this by deleting it).
- OER breakpoints are deleted using `delete_oer_breakpoint`.

62.7.16 GET_VALUE Function

This function gets a value from the currently-running program. There are two overloaded `GET_VALUE` functions.

Syntax

```
DBMS_DEBUG.GET_VALUE (
   variable_name  IN  VARCHAR2,
   frame#         IN  BINARY_INTEGER,
   scalar_value   OUT VARCHAR2,
   format         IN  VARCHAR2 := NULL)
RETURN BINARY_INTEGER;
```

Parameters

Table 62-33 GET_VALUE Function Parameters

Parameter	Description
`variable_name`	Name of the variable or parameter
`frame#`	Frame in which it lives; 0 means the current procedure
`scalar_value`	Value
`format`	Optional date format to use, if meaningful

Return Values

Table 62-34 GET_VALUE Function Return Values

Return	Description
`success`	A successful completion
`error_bogus_frame`	Frame does not exist
`error_no_debug_info`	Entrypoint has no debug information
`error_no_such_object`	`variable_name` does not exist in `frame#`
`error_unknown_type`	The type information in the debug information is illegible
`error_nullvalue`	Value is `NULL`
`error_indexed_table`	The object is a table, but no index was provided

This form of `GET_VALUE` is for fetching package variables. Instead of a frame#, it takes a handle, which describes the package containing the variable.

Syntax

```
DBMS_DEBUG.GET_VALUE (
   variable_name  IN  VARCHAR2,
   handle         IN  program_info,
   scalar_value   OUT VARCHAR2,
   format         IN  VARCHAR2 := NULL)
RETURN BINARY_INTEGER;
```

Parameters

Table 62-35 GET_VALUE Function Parameters

Parameter	Description
variable_name	Name of the variable or parameter
handle	Description of the package containing the variable
scalar_value	Value
format	Optional date format to use, if meaningful

Return Values

Table 62-36 GET_VALUE Function Return Values

Return	Description
error_no_such_object	One of the following: - Package does not exist - Package is not instantiated - User does not have privileges to debug the package - Object does not exist in the package
error_indexed_table	The object is a table, but no index was provided

Examples

This example illustrates how to get the value with a given package PACK in schema SCOTT, containing variable VAR:

```
DECLARE
   handle     dbms_debug.program_info;
   resultbuf  VARCHAR2(500);
   retval     BINARY_INTEGER;
BEGIN
   handle.Owner     := 'SCOTT';
   handle.Name      := 'PACK';
   handle.namespace := dbms_debug.namespace_pkgspec_or_toplevel;
   retval           := dbms_debug.get_value('VAR', handle, resultbuf, NULL);
END;
```

62.7.17 INITIALIZE Function

This function initializes the target session for debugging.

Syntax

```
DBMS_DEBUG.INITIALIZE (
   debug_session_id  IN VARCHAR2       := NULL,
   diagnostics       IN BINARY_INTEGER := 0)
  RETURN VARCHAR2;
```

Parameters

Table 62-37 INITIALIZE Function Parameters

Parameter	Description
debug_session_id	Name of session ID. If NULL, then a unique ID is generated.
diagnostics	Indicates whether to dump diagnostic output to the tracefile: 0 = (default) no diagnostics 1 = print diagnostics

Return Values

The newly-registered debug session ID (debugID)

Usage Notes

You cannot use DBMS_DEBUG and the JDWP-based debugging interface simultaneously. This call will either fail with an ORA-30677 error if the session is currently being debugged with the JDWP-based debugging interface or, if the call succeeds, any further use of the JDWP-based interface to debug this session will be disallowed.

Calls to DBMS_DEBUG will succeed only if either the caller or the specified debug role carries the DEBUG CONNECT SESSION privilege. Failing that, an ORA-1031 error will be raised. Other exceptions are also possible if a debug role is specified but the password does not match, or if the calling user has not been granted the role, or the role is application-enabled and this call does not originate from within the role-enabling package.

The CREATE ANY PROCEDURE privilege does not affect the visibility of routines through the debugger. A privilege DEBUG for each object has been introduced with a corresponding DEBUG ANY PROCEDURE variant. These are required in order to see routines owned by users other than the session's login user.

Authentication of the debug role and the check for DEBUG CONNECT SESSION privilege will be done in the context of the caller to this routine. If the caller is a definer's rights routine or has been called from one, only privileges granted to the defining user, the debug role, or PUBLIC will be used to check for DEBUG CONNECT SESSION. If this call is from within a definer's rights routine, the debug role, if specified, must be one that has been granted to that definer, but it need not also have been granted to the session login user or be enabled in the calling session at the time the call is made.

The checks made by the debugger after this call is made looking for the DEBUG privilege on individual procedures will be done in the context of the session's login user, the roles that were enabled at session level at the moment this call was made (even if those roles were not available within a definer's rights environment of the call), and the debug role.

62.7.18 PING Procedure

This procedure pings the target session to prevent it from timing out. Use this procedure when execution is suspended in the target session, for example at a breakpoint.

If the `timeout_behaviour` is set to `retry_on_timeout` then this procedure is not necessary.

Syntax

```
DBMS_DEBUG.PING;
```

Exceptions

Oracle will display the `no_target_program` exception if there is no target program or if the target session is not currently waiting for input from the debug session.

Usage Notes

Timeout options for the target session are registered with the target session by calling `set_timeout_behaviour`:

- `retry_on_timeout` - Retry. Timeout has no effect. This is like setting the timeout to an infinitely large value.
- `continue_on_timeout` - Continue execution, using same event flags.
- `nodebug_on_timeout` - Turn debug-mode OFF (in other words, call debug_off) and then continue execution. No more events will be generated by this target session unless it is re-initialized by calling debug_on.
- `abort_on_timeout` - Continue execution, using the abort_execution flag, which should cause the program to terminate immediately. The session remains in debug-mode.

```
retry_on_timeout CONSTANT BINARY_INTEGER:= 0;

continue_on_timeout CONSTANT BINARY_INTEGER:= 1;

nodebug_on_timeout CONSTANT BINARY_INTEGER:= 2;

abort_on_timeout CONSTANT BINARY_INTEGER:= 3;
```

62.7.19 PRINT_BACKTRACE Procedure

This procedure prints a backtrace listing of the current execution stack. This should only be called if a program is currently running.

There are two overloaded `PRINT_BACKTRACE` procedures.

Syntax

```
DBMS_DEBUG.PRINT_BACKTRACE (
  listing IN OUT VARCHAR2);

DBMS_DEBUG.PRINT_BACKTRACE (
  backtrace OUT backtrace_table);
```

Parameters

Table 62-38 PRINT_BACKTRACE Procedure Parameters

Parameter	Description
`listing`	A formatted character buffer with embedded newlines
`backtrace`	1-based indexed table of backtrace entries. The currently-running procedure is the last entry in the table (that is, the frame numbering is the same as that used by `GET_VALUE`). Entry 1 is the oldest procedure on the stack.

62.7.20 PRINT_INSTANTIATIONS Procedure

This procedure returns a list of the packages that have been instantiated in the current session.

Syntax

```
DBMS_DEBUG.PRINT_INSTANTIATIONS (
   pkgs   IN OUT NOCOPY backtrace_table,
   flags  IN BINARY_INTEGER);
```

Parameters

Table 62-39 PRINT_INSTANTIATIONS Procedure Parameters

Parameter	Description
`pkgs`	The instantiated packages
`flags`	Bitmask of options: • 1 - show specs • 2 - show bodies • 4 - show local instantiations • 8 - show remote instantiations (NYI) • 16 - do a fast job. The routine does not test whether debug information exists or whether the libunit is shrink-wrapped.

Exceptions

`no_target_program` - target session is not currently executing

Usage Notes

On return, `pkgs` contains a `program_info` for each instantiation. The valid fields are: `Namespace`, `Name`, `Owner`, and `LibunitType`.

In addition, Line# contains a bitmask of:

- 1 - the libunit contains debug info
- 2 - the libunit is shrink-wrapped

62.7.21 PROBE_VERSION Procedure

This procedure returns the version number of DBMS_DEBUG on the server.

Syntax

```
DBMS_DEBUG.PROBE_VERSION (
   major out BINARY_INTEGER,
   minor out BINARY_INTEGER);
```

Parameters

Table 62-40 PROBE_VERSION Procedure Parameters

Parameter	Description
major	Major version number
minor	Minor version number: increments as functionality is added

62.7.22 SELF_CHECK Procedure

This procedure performs an internal consistency check. SELF_CHECK also runs a communications test to ensure that the Probe processes are able to communicate.

If SELF_CHECK does not return successfully, then an incorrect version of DBMS_DEBUG was probably installed on this server. The solution is to install the correct version (pbload.sql loads DBMS_DEBUG and the other relevant packages).

Syntax

```
DBMS_DEBUG.SELF_CHECK (
   timeout IN binary_integer := 60);
```

Parameters

Table 62-41 SELF_CHECK Procedure Parameters

Parameter	Description
timeout	The timeout to use for the communication test. Default is 60 seconds.

Exceptions

Table 62-42 SELF_CHECK Procedure Exceptions

Exception	Description
OER-6516	Probe version is inconsistent
pipe_creation_failure	Could not create a pipe
pipe_send_failure	Could not write data to the pipe
pipe_receive_failure	Could not read data from the pipe
pipe_datatype_mismatch	Datatype in the pipe was wrong

Table 62-42 (Cont.) SELF_CHECK Procedure Exceptions

Exception	Description
pipe_data_error	Data got garbled in the pipe

All of these exceptions are fatal. They indicate a serious problem with Probe that prevents it from working correctly.

62.7.23 SET_BREAKPOINT Function

This function sets a breakpoint in a program unit, which persists for the current session.

Execution pauses if the target program reaches the breakpoint.

Syntax

```
DBMS_DEBUG.SET_BREAKPOINT (
   program     IN  program_info,
   line#       IN  BINARY_INTEGER,
   breakpoint# OUT BINARY_INTEGER,
   fuzzy       IN  BINARY_INTEGER := 0,
   iterations  IN  BINARY_INTEGER := 0)
  RETURN BINARY_INTEGER;
```

Parameters

Table 62-43 SET_BREAKPOINT Function Parameters

Parameter	Description
program	Information about the program unit in which the breakpoint is to be set. (In version 2.1 and later, the namespace, name, owner, and dblink may be set to NULL, in which case the breakpoint is placed in the currently-running program unit.)
line#	Line at which the breakpoint is to be set
breakpoint#	On successful completion, contains the unique breakpoint number by which to refer to the breakpoint
fuzzy	Only applicable if there is no executable code at the specified line: 0 means return error_illegal_line 1 means search forward for an adjacent line at which to place the breakpoint -1 means search backward for an adjacent line at which to place the breakpoint
iterations	Number of times to wait before signalling this breakpoint

Return Values

> **Note:**
>
> The `fuzzy` and `iterations` parameters are not yet implemented

Table 62-44 SET_BREAKPOINT Function Return Values

Return	Description
`success`	A successful completion
`error_illegal_line`	Cannot set a breakpoint at that line
`error_bad_handle`	No such program unit exists

62.7.24 SET_OER_BREAKPOINT Function

This function sets an OER breakpoint.

Syntax

```
DBMS_DEBUG.SET_OER_BREAKPOINT (
   oer  IN PLS_INTEGER)
RETURN PLS_INTEGER;
```

Parameters

Table 62-45 SET_OER_BREAKPOINT Function Parameters

Parameter	Description
`oer`	The OER (positive 4-byte number) to set

Return Values

Table 62-46 SET_OER_BREAKPOINT Function Return Values

Return	Description
`success`	A successful completion
`error_no_such_breakpt`	No such OER breakpoint exists

62.7.25 SET_TIMEOUT Function

This function sets the timeout value and returns the new timeout value.

Syntax

```
DBMS_DEBUG.SET_TIMEOUT (
   timeout BINARY_INTEGER)
  RETURN BINARY_INTEGER;
```

Parameters

Table 62-47 SET_TIMEOUT Function Parameters

Parameter	Description
`timeout`	The timeout to use for communication between the target and debug sessions

62.7.26 SET_TIMEOUT_BEHAVIOUR Procedure

This procedure tells Probe what to do with the target session when a timeout occurs. This call is made in the target session.

Syntax

```
DBMS_DEBUG.SET_TIMEOUT_BEHAVIOUR (
   behaviour IN PLS_INTEGER);
```

Parameters

Table 62-48 SET_TIMEOUT_BEHAVIOUR Procedure Parameters

Parameter	Description
`behaviour - One of the following:`	
`retry_on_timeout`	Retry. Timeout has no effect. This is like setting the timeout to an infinitely large value.
`continue_on_timeout`	Continue execution, using same event flags
`nodebug_on_timeout`	Turn debug-mode OFF (in other words, call `debug_off`) and continue execution. No more events will be generated by this target session unless it is re-initialized by calling `debug_on`.
`abort_on_timeout`	Continue execution, using the `abort_execution` flag, which should cause the program to terminate immediately. The session remains in debug-mode.

Exceptions

unimplemented - the requested behavior is not recognized

Usage Notes

The default behavior (if this procedure is not called) is `continue_on_timeout`, since it allows a debugger client to reestablish control (at the next event) but does not cause the target session to hang indefinitely.

62.7.27 SET_VALUE Function

This function sets a value in the currently-running program. There are two overloaded SET_VALUE functions.

Syntax

```
DBMS_DEBUG.SET_VALUE (
   frame#              IN binary_integer,
   assignment_statement IN varchar2)
  RETURN BINARY_INTEGER;

DBMS_DEBUG.SET_VALUE (
   handle              IN program_info,
   assignment_statement IN VARCHAR2)
  RETURN BINARY_INTEGER;
```

Parameters

Table 62-49 SET_VALUE Function Parameters

Parameter	Description
frame#	Frame in which the value is to be set; 0 means the currently executing frame.
handle	Description of the package containing the variable
assignment_statement	An assignment statement (which must be legal PL/SQL) to run in order to set the value. For example, 'x := 3;'. Only scalar values are supported in this release. The right side of the assignment statement must be a scalar.

Return Values

Table 62-50 SET_VALUE Function Return Values

Return	Description
success	-
error_illegal_value	Not possible to set it to that value
error_illegal_null	Cannot set to NULL because object type specifies it as 'not NULL'
error_value_malformed	Value is not a scalar
error_name_incomplete	The assignment statement does not resolve to a scalar. For example, 'x := 3;', if x is a record.
error_no_such_object	One of the following: - Package does not exist - Package is not instantiated - User does not have privileges to debug the package - Object does not exist in the package

Usage Notes

In some cases, the PL/SQL compiler uses temporaries to access package variables, and does not guarantee to update such temporaries. It is possible, although unlikely, that modification to a package variable using `SET_VALUE` might not take effect for a line or two.

Examples

To set the value of `SCOTT.PACK.var` to 6:

```
DECLARE
   handle  dbms_debug.program_info;
   retval  BINARY_INTEGER;
BEGIN
   handle.Owner     := 'SCOTT';
   handle.Name      := 'PACK';
   handle.namespace := dbms_debug.namespace_pkgspec_or_toplevel;
   retval           := dbms_debug.set_value(handle, 'var := 6;');
END;
```

62.7.28 SHOW_BREAKPOINTS Procedures

There are two overloaded procedures that return a listing of the current breakpoints. There are three overloaded `SHOW_BREAKPOINTS` procedures.

Syntax

```
DBMS_DEBUG.SHOW_BREAKPOINTS (
   listing    IN OUT VARCHAR2);

DBMS_DEBUG.SHOW_BREAKPOINTS (
   listing    OUT breakpoint_table);

DBMS_DEBUG.SHOW_BREAKPOINTS (
   code_breakpoints  OUT breakpoint_table,
   oer_breakpoints   OUT oer_table);
```

Parameters

Table 62-51 SHOW_BREAKPOINTS Procedure Parameters

Parameter	Description
`listing`	A formatted buffer (including newlines) of the breakpoints. Indexed table of breakpoint entries. The breakpoint number is indicated by the index into the table. Breakpoint numbers start at 1 and are reused when deleted.
`code_breakpoints`	The indexed table of breakpoint entries, indexed by breakpoint number
`oer_breakpoints`	The indexed table of OER breakpoints, indexed by OER

62.7.29 SHOW_FRAME_SOURCE Procedure

The procedure gets the source code. There are two overloaded `SHOW_SOURCE` procedures.

Syntax

```
DBMS_DEBUG.SHOW_FRAME_SOURCE (
   first_line  IN            BINARY_INTEGER,
   last_line   IN            BINARY_INTEGER,
   source      IN OUT NOCOPY vc2_table,
   frame_num   IN            BINARY_INTEGER);
```

Parameters

Table 62-52 SHOW_FRAME_SOURCE Procedure Parameters

Parameter	Description
`first_line`	Line number of first line to fetch (PL/SQL programs always start at line 1 and have no holes)
`last_line`	Line number of last line to fetch. No lines are fetched past the end of the program.
`source`	The resulting table, which may be indexed by line#
`frame_num`	1-based frame number

Usage Notes

- You use this function only when backtrace shows an anonymous unit is executing at a given frame position and you need to view the source in order to set a breakpoint.
- If frame number is top of the stack and it's an anonymous block then `SHOW_SOURCE` can also be used.
- If it's a stored PL/SQL package/function/procedure then use SQL as described in the Usage Notes to SHOW_SOURCE Procedures.

62.7.30 SHOW_SOURCE Procedures

The procedure gets the source code. There are two overloaded `SHOW_SOURCE` procedures.

Syntax

```
DBMS_DEBUG.SHOW_SOURCE (
   first_line  IN   BINARY_INTEGER,
   last_line   IN   BINARY_INTEGER,
   source      OUT  vc2_table);

DBMS_DEBUG.SHOW_SOURCE (
   first_line   IN     BINARY_INTEGER,
   last_line    IN     BINARY_INTEGER,
   window       IN     BINARY_INTEGER,
   print_arrow  IN     BINARY_INTEGER,
   buffer       IN OUT VARCHAR2,
   buflen       IN     BINARY_INTEGER,
   pieces       OUT    BINARY_INTEGER);
```

Parameters

Table 62-53 SHOW_SOURCE Procedure Parameters

Parameter	Description
`first_line`	Line number of first line to fetch (PL/SQL programs always start at line 1 and have no holes)
`last_line`	Line number of last line to fetch. No lines are fetched past the end of the program.
`source`	The resulting table, which may be indexed by line#
`window`	'Window' of lines (the number of lines around the current source line)
`print_arrow`	Nonzero means to print an arrow before the current line
`buffer`	Buffer in which to place the source listing
`buflen`	Length of buffer
`pieces`	Set to nonzero if not all the source could be placed into the given buffer

Return Values

An indexed table of source-lines. The source lines are stored starting at `first_line`. If any error occurs, then the table is empty.

Usage Notes

The best way to get the source code (for a program that is being run) is to use SQL. For example:

```
DECLARE
    info DBMS_DEBUG.runtime_info;
BEGIN
   -- call DBMS_DEBUG.SYNCHRONIZE, CONTINUE,
   -- or GET_RUNTIME_INFO to fill in 'info'
   SELECT text INTO <buffer> FROM all_source
   WHERE owner = info.Program.Owner
     AND name  = info.Program.Name
     AND line  = info.Line#;
END;
```

However, this does not work for nonpersistent programs (for example, anonymous blocks and trigger invocation blocks). For nonpersistent programs, call `SHOW_SOURCE`. There are two flavors: one returns an indexed table of source lines, and the other returns a packed (and formatted) buffer.

The second overloading of `SHOW_SOURCE` returns the source in a formatted buffer, complete with line-numbers. It is faster than the indexed table version, but it does not guarantee to fetch all the source.

If the source does not fit in bufferlength (`buflen`), then additional pieces can be retrieved using the `GET_MORE_SOURCE` procedure (`pieces` returns the number of additional pieces that need to be retrieved).

62.7.31 SYNCHRONIZE Function

This function waits until the target program signals an event. If `info_requested` is not `NULL`, then it calls `GET_RUNTIME_INFO`.

Syntax

```
DBMS_DEBUG.SYNCHRONIZE (
   run_info       OUT  runtime_info,
   info_requested IN   BINARY_INTEGER := NULL)
  RETURN BINARY_INTEGER;
```

Parameters

Table 62-54 SYNCHRONIZE Function Parameters

Parameter	Description
`run_info`	Structure in which to write information about the program. By default, this includes information about what program is running and at which line execution has paused.
`info_requested`	Optional bit-field in which to request information other than the default (which is `info_getStackDepth` + `info_getLineInfo`). 0 means that no information is requested at all (see DBMS_DEBUG Operational Notes for more about information flags).

Return Values

Table 62-55 SYNCHRONIZE Function Return Values

Return	Description
`success`	A successful completion
`error_timeout`	Timed out before the program started execution
`error_communication`	Other communication error

62.7.32 TARGET_PROGRAM_RUNNING Procedure

This procedure returns `TRUE` if the target session is currently executing a stored procedure, or `FALSE` if it is not.

Syntax

```
DBMS_DEBUG.TARGET_PROGRAM_RUNNING
  RETURN BOOLEAN;
```

63
DBMS_DEBUG_JDWP

The DBMS_DEBUG_JDWP provides the interface to initiate and control the debugging of PL/SQL stored procedures and Java stored procedures over Java Debug Wire Protocol (JDWP).

This chapter contains the following topics:

- DBMS_DEBUG_JDWP Overview
- DBMS_DEBUG_JDWP Security Model
- Summary of DBMS_DEBUG_JDWP Subprograms

63.1 DBMS_DEBUG_JDWP Overview

Oracle supports the debugging of PL/SQL stored procedures and Java stored procedures over JDWP. Using the DBMS_DEBUG_JDWP package, you can:

- Retrieve the session ID of the current session and serial number
- Connect a database session to a debugger over JDWP
- Set the NLS parameters to change the formats in which PL/SQL program values are represented over JDWP

63.2 DBMS_DEBUG_JDWP Security Model

The debugging user invoking a DBMS_DEBUG_JDWP subprogram requires a privilege to connect the target database session to the debugger.

Table 63-1 System Privileges

System Privilege	Description
DEBUG CONNECT SESSION	Allows a user to connect his current session to a debugger
DEBUG CONNECT ANY	Allows a user to connect a session by any logon user to a debugger

In addition, the user can also be granted the following user privilege to debug another user's session.

Table 63-2 User Privileges

User Privilege	Description
DEBUG CONNECT ON USER <*user*>	Allows a user to connect any of the specified user's logon sessions to a debugger to debug another user's session or his own

63.3 Summary DBMS_DEBUG_JDWP Subprograms

This table lists the DBMS_DEBUG_JDWP subprograms and briefly describes them.

Table 63-3 DBMS_DEBUG_JDWP Package Subprograms

Subprogram	Description
CONNECT_TCP Procedure	Connects the specified session to the debugger waiting at host:port
CURRENT_SESSION_ID Function	Gets the current session's session ID
CURRENT_SESSION_SERIAL Function	Gets the current session's session serial number
DISCONNECT Procedure	Disconnects the specified session from any debugger with which it is connected
GET_NLS_PARAMETER Function	Gets the value of the specified NLS parameter affecting the format in which NUMBER, DATE, TIME (WITH TIME ZONE) and TIMESTAMP (WITH TIME ZONE) runtime values of PL/SQL programs are converted to strings as they are presented through JDWP
PROCESS_CONNECT_STRING Procedure	Connects a session to a debugger without having to directly modify an application's code
SET_NLS_PARAMETER Procedure	Sets the value of the specified NLS parameter affecting the format in which NUMBER, DATE, TIME (WITH TIME ZONE) and TIMESTAMP (WITH TIME ZONE) runtime values of PL/SQL programs are converted to strings as they are presented through JDWP

63.3.1 CONNECT_TCP Procedure

This procedure connects the specified session to the debugger waiting at host:port.

Syntax

```
DBMS_DEBUG_JDWP.CONNECT_TCP(
   host                 IN  VARCHAR2,
   port                 IN  VARCHAR2,
   session_id           IN  PLS_INTEGER := NULL,
   session_serial       IN  PLS_INTEGER := NULL,
   debug_role           IN  VARCHAR2  := NULL,
   debug_role_pwd       IN  VARCHAR2  := NULL,
   option_flags         IN  PLS_INTEGER := 0,
   extensions_cmd_set   IN  PLS_INTEGER := 128);
```

Parameters

Table 63-4 CONNECT_TCP Parameters

Parameter	Description
host	The host name the debugger is waiting at

Table 63-4 (Cont.) CONNECT_TCP Parameters

Parameter	Description
`port`	The port number the debugger is waiting at
`session_id`	Session ID
`session_serial`	Session number
`debug_role`	Debug role
`debug_role_pwd`	Debug password
`option_flags`	Values: • 1 : Does not suspend the program until the next client/server request begins. This can be used to hide the startup sequence from end users, who may only want to see their own code • 2 : Forces the connection even if the session appears to be connected to a debugger. This should best only be specified after some human-interaction confirmation step has occurred; i.e., if an attempt without this option raised ORA-30677, then if the user confirms, retry with this bit set. These may be added together to select multiple option choices.
`extensions_cmd_set`	The ID of the Oracle JDWP extension command set

Exceptions

Table 63-5 CONNECT_TCP Exceptions

Exception	Description
`ORA-00022`	Invalid session ID
`ORA-01031`	Insufficient privilege
`ORA-30677`	Session is already connected to a debugger
`ORA-30681`	Improper value for argument `EXTENSIONS_CMD_SET`
`ORA-30682`	Improper value for argument `OPTION_FLAGS`
`ORA-30683`	Failure establishing connection to debugger

Usage Notes

- To connect the current session to a debugger, you can pass `NULL` to both the `session_id` and `session_serial` parameters.
- To connect a different session, you need to find out its ID and serial. These are available in the `v$plsql_debuggable_sessions` view. The Instance Manager option of Oracle Enterprise Manager is one example of a user interface that displays these values to

users. You can also find the values of these for your own session using the CURRENT_SESSION_ID Function and CURRENT_SESSION_SERIAL Function.

- The `debug_role` and `debug_role_pwd` arguments allow the user to name any role as the "debug role", which will be available to privilege checking when checking for permissions to connect the session and when checking permissions available on objects within the debugged session. Both the role and its password are passed here as strings and not as identifiers, so double quotes should not be used but case matters. If the original role name wasn't double-quoted, it should be specified here in upper case.
- An `ORA-30677` indicates that the requested session is already being debugged. It is suggested in this case that the user be asked to confirm that (s)he desires to steal the session from the existing connection, and then either an explicit disconnect call or the use of the `connect_force_connect` option bit can be used to allow the connection to succeed on a second attempt. Note that using the `connect_force_connect` bit will avoid the session being allowed to run freely if it is currently suspended through the debugger - in other words, this bit lets you steal a session from one debugger to another without actually disturbing the state of the session.

63.3.2 CURRENT_SESSION_ID Function

This function gets the current session's session ID

Syntax

```
DBMS_DEBUG_JDWP.CURRENT_SESSION_ID
  RETURN PLS_INTEGER;
```

63.3.3 CURRENT_SESSION_SERIAL Function

This function gets the current session's session number.

Syntax

```
DBMS_DEBUG_JDWP.CURRENT_SESSION_SERIAL
  RETURN PLS_INTEGER;
```

63.3.4 DISCONNECT Procedure

This procedure disconnects the specified session from any debugger with which it is connected.

Syntax

```
DBMS_DEBUG_JDWP.DISCONNECT(
   session_id        IN  PLS_INTEGER  := NULL,
   session_serial    IN  PLS_INTEGER := NULL);
```

Parameters

Table 63-6 DISCONNECT Procedure Parameters

Parameter	Description
session_id	Session ID
session_serial	Session number

Usage Notes

- If the session to disconnect is the current session, the session will be allowed to run freely after disconnecting the debugger. Otherwise, the session will be terminated.
- The same rights are required for this call as for connect, except when disconnecting the current session and the effective user at the time of the call is the same as the login user of the session where no privilege is required.

63.3.5 GET_NLS_PARAMETER Function

This function gets the value of the specified NLS parameter affecting the format in which the NUMBER, DATE, TIME (WITH TIME ZONE) and TIMESTAMP (WITH TIME ZONE) runtime values of PL/SQL programs are converted to strings, as they are presented through JDWP.

These values are private to the current session, but further are private to the debugger mechanisms, separate from the values used to convert values within the debugged program itself.

Syntax

```
DBMS_DEBUG_JDWP.GET_NLS_PARAMETER(
   name   IN  VARCHAR2)
  RETURN VARCHAR2;
```

Parameters

Table 63-7 GET_NLS_PARAMETER Function Parameters

Parameter	Description
name	Specified NLS parameter

Usage Notes

- When any variable value is read or assigned through JDWP, or when either GET_NLS_PARAMETER Function or SET_NLS_PARAMETER Procedure is first invoked in a session, the debugger mechanisms make a private copy of the then-current NLS_LANGUAGE, NLS_TERRITORY, NLS_CALENDAR, NLS_DATE_LANGUAGE, NLS_NUMERIC_CHARACTERS, NLS_TIMESTAMP_FORMAT, NLS_TIMESTAMP_TZ_FORMAT, NLS_TIME_FOMAT and NLS_TIME_TZ_FORMAT values. These private copies may be read using this GET_NLS_PARAMETER Functioncall and changed using the following call to the SET_NLS_PARAMETER Procedure.
- Once the debugger's private copy of the NLS parameters is established, changes made to the NLS parameters in the current session using the ALTER SESSION statement will

have no effect on the formatting of values as seen through JDWP. To modify the NLS parameters used for JDWP, one must use the `SET_NLS_PARAMETER Procedure` . By the same token, changes made to the debugger's private copy of the NLS parameters using`SET_NLS_PARAMETER Procedure` will have no effect on the debugged program itself.

- Date values are always formatted for JDWP use using the `NLS_TIMESTAMP_FORMAT`. The default format for `DATE (NLS_DATE_FORMAT)` used in a session most often does not show the time information that is in fact present in the value, and for debugging purposes it seems beneficial to always display that information.

63.3.6 PROCESS_CONNECT_STRING Procedure

This procedure connects a session to a debugger in two ways, so that you do not have to directly modify the application code.

The two ways are:

- Using the `ORA_DEBUG_JDWP` environment variable, when running an OCI program
- Setting a web browser cookie called `OWA_DEBUG_<dad>`, when running an application through the PL/SQL Web Gateway

Syntax

```
DBMS_DEBUG_JDWP.PROCESS_CONNECT_STRING (
   connect_string          IN  VARCHAR2,
   connect_string_type     IN  PLS_INTEGER);
```

Parameters

Table 63-8 PROCESS_CONNECT_STRING Procedure Parameters

Parameter	Description
`connect_string`	The `ORA_DEBUG_JDWP` environment variable or `OWA_DEBUG_<dad>` cookie value that contains the JDWP connection information such as the host and port number of the debugger to connect to
`connect_string_type`	Can have the following two values: • 1 if the connect string value is retrieved from the `ORA_DEBUG_JDWP` environment • 2 if the value is from the `OWA_DEBUG_<dad>` cookie

Exceptions

Table 63-9 PROCESS_CONNECT_STRING Procedure Exceptions

Exception	Description
`ORA-00022`	Invalid session ID
`ORA-01031`	Insufficient privilege
`ORA-30677`	Session is already connected to a debugger

Table 63-9 (Cont.) PROCESS_CONNECT_STRING Procedure Exceptions

Exception	Description
ORA-30681	Improper value for argument EXTENSIONS_CMD_SET
ORA-30682	Improper value for argument OPTION_FLAGS
ORA-30683	Failure establishing connection to debugger
ORA-30689	Improper value for environment variable ORA_DEBUG_JDWP

63.3.7 SET_NLS_PARAMETER Procedure

This function sets the value of the specified NLS parameter affecting the format in which NUMBER, DATE, TIME (WITH TIME ZONE) and TIMESTAMP (WITH TIME ZONE) runtime values of PL/SQL programs are converted to strings as they are presented through JDWP.

These values are private to the current session, but further are private to the debugger mechanisms, separate from the values used to convert values within the debugged program itself.

Syntax

```
DBMS_DEBUG_JDWP.SET_NLS_PARAMETER(
   name      IN  VARCHAR2,
   value     IN  VARCHAR2);
```

Parameters

Table 63-10 SET_NLS_PARAMETER Procedure Parameters

Parameter	Description
name	Specified NLS parameter
value	Value of specified NLS parameter

Usage Notes

- When any variable value is read or assigned through JDWP, or when either GET_NLS_PARAMETER Function or SET_NLS_PARAMETER Procedure is first invoked in a session, the debugger mechanisms make a private copy of the then-current NLS_LANGUAGE, NLS_TERRITORY, NLS_CALENDAR, NLS_DATE_LANGUAGE, NLS_NUMERIC_CHARACTERS, NLS_TIMESTAMP_FORMAT, NLS_TIMESTAMP_TZ_FORMAT, NLS_TIME_FOMAT and NLS_TIME_TZ_FORMAT values. These private copies may be read by calling the GET_NLS_PARAMETER Function and changed using the following call to the SET_NLS_PARAMETER Procedure.
- Once the debugger's private copy of the NLS parameters is established, changes made to the NLS parameters in the current session using the ALTER SESSION statement will have no effect on the formatting of values as seen through JDWP. To modify the NLS parameters used for JDWP, one must use the SET_NLS_PARAMETER Procedure. By the same token, changes made to the debugger's private copy of the NLS parameters usingSET_NLS_PARAMETER Procedure will have no effect on the debugged program itself.

- Date values are always formatted for JDWP use using the `NLS_TIMESTAMP_FORMAT`. The default format for `DATE (NLS_DATE_FORMAT)` used in a session most often does not show the time information that is in fact present in the value, and for debugging purposes it seems beneficial to always display that information.

64
DBMS_DEBUG_JDWP_CUSTOM

The DBMS_DEBUG_JDWP_CUSTOM package provides database users a means to perform custom handling of a debug connection request of a database session to a debugger using the Java Debug Wire Protocol (JDWP).

This chapter contains the following topics:

- DBMS_DEBUG_JDWP_CUSTOM Overview
- DBMS_DEBUG_JDWP_CUSTOM Security Model
- Summary of DBMS_DEBUG_JDWP_CUSTOM Subprograms

64.1 DBMS_DEBUG_JDWP_CUSTOM Overview

DBMS_DEBUG_JDWP_CUSTOM package is invoked when you attempt to connect your database session to a debugger, using the Java Debug Wire Protocol (JDWP). Before connecting to the database, you must set the ORA_DEBUG_JDWP environment variable in your client-side OCI application. Defining this package in your schema enables you to perform custom actions before connecting your database session to the debugger.

64.2 DBMS_DEBUG_JDWP_CUSTOM Security Model

This default implementation of the DBMS_DEBUG_JDWP_CUSTOM package does not perform any additional security checks and only invokes the DBMS_DEBUG_JDWP package for making the debug connection. When the DBMS_DEBUG_JDWP package is invoked, it checks for the necessary DEBUG CONNECT system or user privilege before making the connection.

A database user who wants to perform additional custom security checks, must perform the following steps to override this default implementation:

- Define the DBMS_DEBUG_JDWP_CUSTOM package in the user's own schema.
- Implement the check before invoking the DBMS_DEBUG_JDWP package in the user's local copy of the package.

64.3 Summary DBMS_DEBUG_JDWP_CUSTOM Subprograms

This table summarizes the DBMS_DEBUG_JDWP_CUSTOM subprograms.

Table 64-1 DBMS_DEBUG_JDWP_CUSTOM Subprograms

Subprogram	Description
CONNECT_DEBUGGER Procedure	This procedure is invoked to handle the debug connection request of the current database session to the debugger.

64.3.1 CONNECT_DEBUGGER Procedure

This procedure is invoked to handle the debug connection request of the current database session to the debugger.

Syntax

```
PROCEDURE CONNECT_DEBUGGER
(
   HOST                VARCHAR2,
   PORT                VARCHAR2,
   DEBUG_ROLE          VARCHAR2 := NULL,
   DEBUG_ROLE_PWD      VARCHAR2 := NULL,
   OPTION_FLAGS        PLS_INTEGER := 0,
   EXTENSIONS_CMD_SET  PLS_INTEGER := 128
)
```

Parameters

The preceding parameters are for the default implementation of the procedure for handling the debug connection request. A user, who wants to customize the handling of the request, must override this default implementation of the `DBMS_DEBUG_JDWP_CUSTOM` package procedure by defining the package (specification and body) with a procedure of the same name in the user's own schema. The user may customize the number and names of the arguments, but must have the same name for the package and the procedure, namely, `DBMS_DEBUG_JDWP_CUSTOM` and `CONNECT_DEBUGGER` respectively. The user's customized version of the package may contain overloaded versions of the `CONNECT_DEBUGGER` procedure with different arguments. All of the arguments to the custom package procedure must either be of VARCHAR2 type or of types that PL/SQL can implicitly convert from VARCHAR2.

For example, if a user wants to disallow debugging outside business hours, while applying optional NLS settings to the program values displayed during debugging, then the user can define a custom implementation of the package in the user's schema in the following way:

```
CREATE OR REPLACE PACKAGE DBMS_DEBUG_JDWP_CUSTOM AUTHID CURRENT_USER IS
  PROCEDURE CONNECT_DEBUGGER(HOST VARCHAR2,
                             PORT VARCHAR2,
                             NLS_LANGUAGE VARCHAR2 DEFAULT NULL,
                             NLS_TERRITORY VARCHAR2 DEFAULT NULL);
END;
/

CREATE OR REPLACE PACKAGE BODY DBMS_DEBUG_JDWP_CUSTOM IS

  PROCEDURE CONNECT_DEBUGGER(HOST VARCHAR2,
                             PORT VARCHAR2,
                             NLS_LANGUAGE VARCHAR2 DEFAULT NULL,
                             NLS_TERRITORY VARCHAR2 DEFAULT NULL) IS
  BEGIN
    SELECT EXTRACT(HOUR FROM LOCALTIMESTAMP) INTO HOUR FROM DUAL;
```

```
    IF (HOUR < 9 OR HOUR > 5) THEN
      RAISE_APPLICATION_ERROR(-20000,
        'Debug connection disallowed outside business hours');
    ELSE
      IF (NLS_LANGUAGE IS NOT NULL) THEN
        DBMS_DEBUG_JDWP.SET_NLS_PARAMETER('NLS_LANGUAGE', NLS_LANGUAGE);
      END IF;
      IF (NLS_TERRITORY IS NOT NULL) THEN
        DBMS_DEBUG_JDWP.SET_NLS_PARAMETER('NLS_TERRITORY', NLS_TERRITORY);
      END IF;
      DBMS_DEBUG_JDWP.CONNECT_TCP(HOST, PORT);
    END IF;
  END;

END;
/
```

Before executing the client application for passing arguments to the procedure parameters, the user must set the `ORA_DEBUG_JDWP` environment variable as follows :

```
> setenv ORA_DEBUG_JDWP "host=123.45.67.89;port=4000;nls_language=american"
> myapp -user hr/hr
...
```

65
DBMS_DESCRIBE

You can use the DBMS_DESCRIBE package to get information about a PL/SQL object. When you specify an object name, DBMS_DESCRIBE returns a set of indexed tables with the results. Full name translation is performed and security checking is also checked on the final object.

This chapter contains the following topics:

- Overview
- Security Model
- Types
- Exceptions
- Examples
- Summary of DBMS_DESCRIBE Subprograms

65.1 DBMS_DESCRIBE Overview

This package provides the same functionality as the Oracle Call Interface OCIDescribeAny call.

> **See Also:**
>
> *Oracle Call Interface Programmer's Guide*

65.2 DBMS_DESCRIBE Security Model

This package is available to PUBLIC and performs its own security checking based on the schema object being described.

65.3 DBMS_DESCRIBE Types

The DBMS_DESCRIBE package declares two PL/SQL table types, which are used to hold data returned by DESCRIBE_PROCEDURE in its OUT parameters.

The types are:

```
TYPE VARCHAR2_TABLE IS TABLE OF VARCHAR2(30)
    INDEX BY BINARY_INTEGER;

TYPE NUMBER_TABLE IS TABLE OF NUMBER
    INDEX BY BINARY_INTEGER;
```

65.4 DBMS_DESCRIBE Exceptions

DBMS_DESCRIBE can raise application errors in the range -20000 to -20004.

Table 65-1 DBMS_DESCRIBE Errors

Error	Description
ORA-20000	ORU 10035: cannot describe a package ('X') only a procedure within a package.
ORA-20001	ORU-10032: procedure 'X' within package 'Y' does not exist.
ORA-20002	ORU-10033: object 'X' is remote, cannot describe; expanded name 'Y'.
ORA-20003	ORU-10036: object 'X' is invalid and cannot be described.
ORA-20004	Syntax error attempting to parse 'X'.

65.5 DBMS_DESCRIBE Examples

One use of the DESCRIBE_PROCEDURE procedure is as an external service interface.

For example, consider a client that provides an OBJECT_NAME of SCOTT.ACCOUNT_UPDATE, where ACCOUNT_UPDATE is an overloaded function with specification:

```
TABLE account (accnt_no NUMBER, person_id NUMBER,
               balance NUMBER(7,2))
TABLE person  (person_id number(4), person_nm varchar2(10))

CREATE OR REPLACE PACKAGE ACCOUNT_PKG is   FUNCTION ACCOUNT_UPDATE (accnt_no
NUMBER,
                            person      person%rowtype,
                            amounts     DBMS_DESCRIBE.NUMBER_TABLE,
                            trans_date  DATE)
                            return       account.balance%type;

   FUNCTION ACCOUNT_UPDATE (accnt_no     NUMBER,
                            person       person%rowtype,
                            amounts      DBMS_DESCRIBE.NUMBER_TABLE,
                            trans_no     NUMBER)
                            return       account.balance%type;
END;
```

This procedure might look similar to the following output:

```
overload position  argument level  datatype length prec scale rad
-------- --------- -------- ------ -------- ------ ---- ----- ---
       1         0                0        2     22    7     2  10
       1         1   ACCNT_NO     0        2      0    0     0   0
       1         2   PERSON       0      250      0    0     0   0
       1         1   PERSON_ID    1        2     22    4     0  10
       1         2   PERSON_NM    1        1     10    0     0   0
       1         3   AMOUNTS      0      251      0    0     0   0
       1         1                1        2     22    0     0   0
       1         4   TRANS_DATE   0       12      0    0     0   0
       2         0                0        2     22    7     2  10
       2         1   ACCNT_NO     0        2     22    0     0   0
```

```
       2        2   PERSON      0         2     22    4     0  10
       2        3   AMOUNTS     0       251     22    4     0  10
       2        1               1         2      0    0     0   0
       2        4   TRANS_NO    0         2      0    0     0   0
```

The following PL/SQL procedure has as its parameters all of the PL/SQL datatypes:

```
CREATE OR REPLACE PROCEDURE p1 (
        pvc2    IN     VARCHAR2,
        pvc     OUT    VARCHAR,
        pstr    IN OUT STRING,
        plong   IN     LONG,
        prowid  IN     ROWID,
        pchara  IN     CHARACTER,
        pchar   IN     CHAR,
        praw    IN     RAW,
        plraw   IN     LONG RAW,
        pbinint IN     BINARY_INTEGER,
        pplsint IN     PLS_INTEGER,
        pbool   IN     BOOLEAN,
        pnat    IN     NATURAL,
        ppos    IN     POSITIVE,
        pposn   IN     POSITIVEN,
        pnatn   IN     NATURALN,
        pnum    IN     NUMBER,
        pintgr  IN     INTEGER,
        pint    IN     INT,
        psmall  IN     SMALLINT,
        pdec    IN     DECIMAL,
        preal   IN     REAL,
        pfloat  IN     FLOAT,
        pnumer  IN     NUMERIC,
        pdp     IN     DOUBLE PRECISION,
        pdate   IN     DATE,
        pmls    IN     MLSLABEL) AS

BEGIN
    NULL;
END;
```

If you describe this procedure using the following:

```
CREATE OR REPLACE PACKAGE describe_it AS

    PROCEDURE desc_proc (name VARCHAR2);

END describe_it;

CREATE OR REPLACE PACKAGE BODY describe_it AS

  PROCEDURE prt_value(val VARCHAR2, isize INTEGER) IS
    n INTEGER;
  BEGIN
    n := isize - LENGTHB(val);
    IF n < 0 THEN
      n := 0;
    END IF;
    DBMS_OUTPUT.PUT(val);
    FOR i in 1..n LOOP
      DBMS_OUTPUT.PUT(' ');
    END LOOP;
```

```
  END prt_value;

  PROCEDURE desc_proc (name VARCHAR2) IS

      overload     DBMS_DESCRIBE.NUMBER_TABLE;
      position     DBMS_DESCRIBE.NUMBER_TABLE;
      c_level      DBMS_DESCRIBE.NUMBER_TABLE;
      arg_name     DBMS_DESCRIBE.VARCHAR2_TABLE;
      dty          DBMS_DESCRIBE.NUMBER_TABLE;
      def_val      DBMS_DESCRIBE.NUMBER_TABLE;
      p_mode       DBMS_DESCRIBE.NUMBER_TABLE;
      length       DBMS_DESCRIBE.NUMBER_TABLE;
      precision    DBMS_DESCRIBE.NUMBER_TABLE;
      scale        DBMS_DESCRIBE.NUMBER_TABLE;
      radix        DBMS_DESCRIBE.NUMBER_TABLE;
      spare        DBMS_DESCRIBE.NUMBER_TABLE;
      idx          INTEGER := 0;

  BEGIN
      DBMS_DESCRIBE.DESCRIBE_PROCEDURE(
              name,
              null,
              null,
              overload,
              position,
              c_level,
              arg_name,
              dty,
              def_val,
              p_mode,
              length,
              precision,
              scale,
              radix,
              spare);

      DBMS_OUTPUT.PUT_LINE('Position    Name        DTY  Mode');
      LOOP
          idx := idx + 1;
          prt_value(TO_CHAR(position(idx)), 12);
          prt_value(arg_name(idx), 12);
          prt_value(TO_CHAR(dty(idx)), 5);
          prt_value(TO_CHAR(p_mode(idx)), 5);
          DBMS_OUTPUT.NEW_LINE;
      END LOOP;
  EXCEPTION
     WHEN NO_DATA_FOUND THEN
        DBMS_OUTPUT.NEW_LINE;
        DBMS_OUTPUT.NEW_LINE;

  END desc_proc;
END describe_it;
```

Then the results list all the numeric codes for the PL/SQL datatypes:

```
Position  Name    Datatype_Code  Mode
1         PVC2      1              0
2         PVC       1              1
3         PSTR      1              2
4         PLONG     8              0
5         PROWID    11             0
```

```
6          PCHARA     96              0
7          PCHAR      96              0
8          PRAW       23              0
9          PLRAW      24              0

13         PNAT       3               0
14         PPOS       3               0
15         PPOSN      3               0
16         PNATN      3               0
17         PNUM       2               0
18         PINTGR     2               0
19         PINT       2               0
20         PSMALL     2               0
21         PDEC       2               0
22         PREAL      2               0
23         PFLOAT     2               0
24         PNUMER     2               0
25         PDP        2               0
26         PDATE      12              0
27         PMLS       106             0
```

65.6 Summary of DBMS_DESCRIBE Subprograms

The DBMS_DESCRIBE package includes the DESCRIBE_PROCEDURE procedure.

Table 65-2 DBMS_DESCRIBE Package Subprograms

Subprogram	Description
DESCRIBE_PROCEDURE Procedure	Provides a brief description of a PL/SQL stored procedure

65.6.1 DESCRIBE_PROCEDURE Procedure

The procedure DESCRIBE_PROCEDURE provides a brief description of a PL/SQL stored procedure.

It takes the name of a stored procedure and returns information about each parameter of that procedure.

Syntax

```
DBMS_DESCRIBE.DESCRIBE_PROCEDURE(
   object_name                    IN  VARCHAR2,
   reserved1                      IN  VARCHAR2,
   reserved2                      IN  VARCHAR2,
   overload                       OUT NUMBER_TABLE,
   position                       OUT NUMBER_TABLE,
   level                          OUT NUMBER_TABLE,
   argument_name                  OUT VARCHAR2_TABLE,
   datatype                       OUT NUMBER_TABLE,
   default_value                  OUT NUMBER_TABLE,
   in_out                         OUT NUMBER_TABLE,
   length                         OUT NUMBER_TABLE,
   precision                      OUT NUMBER_TABLE,
   scale                          OUT NUMBER_TABLE,
```

```
  radix                         OUT NUMBER_TABLE,
  spare                         OUT NUMBER_TABLE
  include_string_constraints    OUT BOOLEAN DEFAULT FALSE);
```

Parameters

Table 65-3 DBMS_DESCRIBE.DESCRIBE_PROCEDURE Parameters

Parameter	Description
`object_name`	Name of the procedure being described. The syntax for this parameter follows the rules used for identifiers in SQL. The name can be a synonym. This parameter is required and may not be null. The total length of the name cannot exceed 197 bytes. An incorrectly specified `OBJECT_NAME` can result in one of the following exceptions: `ORA-20000` - A package was specified. You can only specify a stored procedure, stored function, packaged procedure, or packaged function. `ORA-20001` - The procedure or function that you specified does not exist within the given package. `ORA-20002` - The object that you specified is a remote object. This procedure cannot currently describe remote objects. `ORA-20003` - The object that you specified is invalid and cannot be described. `ORA-20004` - The object was specified with a syntax error.
`reserved1` `reserved2`	Reserved for future use -- must be set to `NULL` or the empty string.
`overload`	A unique number assigned to the procedure's signature. If a procedure is overloaded, then this field holds a different value for each version of the procedure.
`position`	Position of the argument in the parameter list. Position 0 returns the values for the return type of a function.
`level`	If the argument is a composite type, such as record, then this parameter returns the level of the datatype. See the *Oracle Call Interface Programmer's Guide* for a description of the `ODESSP` call for an example.
`argument_name`	Name of the argument associated with the procedure that you are describing.

Table 65-3 (Cont.) DBMS_DESCRIBE.DESCRIBE_PROCEDURE Parameters

Parameter	Description
datatype	Oracle datatype of the argument being described. The datatypes and their numeric type codes are: 0 placeholder for procedures with no arguments 1 VARCHAR, VARCHAR, STRING 2 NUMBER, INTEGER, SMALLINT, REAL, FLOAT, DECIMAL 3 BINARY_INTEGER, PLS_INTEGER, POSITIVE, NATURAL 8 LONG 11 ROWID 12 DATE 23 RAW 24 LONG RAW 58 OPAQUE TYPE 96 CHAR (ANSI FIXED CHAR), CHARACTER 106 MLSLABEL 121 OBJECT 122 NESTED TABLE 123 VARRAY 178 TIME 179 TIME WITH TIME ZONE 180 TIMESTAMP 181 TIMESTAMP WITH TIME ZONE 231 TIMESTAMP WITH LOCAL TIME ZONE 250 PL/SQL RECORD 251 PL/SQL TABLE 252 PL/SQL BOOLEAN
default_value	1 if the argument being described has a default value; otherwise, the value is 0.
in_out	Describes the mode of the parameter: 0 IN 1 OUT 2 IN OUT
length	For %rowtype formal arguments, the length constraint is returned, otherwise 0 is returned.If the include_string_constraints parameter is set to TRUE, the argument's formal length constraint is passed back if it is of the appropriate type. Those are the string types: 1;8;23;24;96
precision	If the argument being described is of datatype 2 (NUMBER), then this parameter is the precision of that number.
scale	If the argument being described is of datatype 2 (NUMBER), then this parameter is the scale of that number.
radix	If the argument being described is of datatype 2 (NUMBER), then this parameter is the radix of that number.
spare	Reserved for future functionality.
include_string_constraints	The default is FALSE. If the parameter is set to TRUE, the arguments' formal type constraints is passed back if it is of the appropriate type.Those are the string types: 1;8;23;24;96

Return Values

All values from `DESCRIBE_PROCEDURE` are returned in its `OUT` parameters. The datatypes for these are PL/SQL tables, to accommodate a variable number of parameters.

66
DBMS_DG

The DBMS_DG package allows applications to notify the primary database or the fast-start failover target database in an Oracle Data Guard broker environment to initiate a fast-start failover when the application encounters a condition that warrants a failover.

> **Note:**
>
> A multitenant container database is the only supported architecture in Oracle Database 20c. While the documentation is being revised, legacy terminology may persist. In most cases, "database" and "non-CDB" refer to a CDB or PDB, depending on context. In some contexts, such as upgrades, "non-CDB" refers to a non-CDB from a previous release.

This chapter contains the following topics:

- Using DBMS_DG
- Security Model
- Summary of the DBMS_DG Subprogram

> **See Also:**
>
> *Oracle Data Guard Broker*

66.1 Using DBMS_DG

There are conditions detectable by applications running outside of the Oracle database that may warrant the Oracle Data Guard broker to perform a fast-start failover. Because the range of possible conditions is virtually unlimited, it is left to the applications to determine which conditions warrant a fast-start failover.

When such conditions occur, the application calls the DBMS_DG.INITIATE_FS_FAILOVER procedure to alert either the primary or fast-start failover target standby database that the application wants a fast-start failover to occur immediately. The database on which the procedure was called then notifies the observer, which immediately initiates a fast-start failover as long as the standby database is in a valid fast-start failover state ("observed" and either "synchronized" or "within lag") to accept a failover.If the configuration is not in a valid fast-start failover state, the INITIATE_FS_FAILOVER subprogram returns an ORA error message (it will not signal an exception) to inform the calling application that a fast-start failover could not be performed.

> **Note:**
>
> If you are working in a multitenant container database (CDB), then functions within DBMS_DG are only executed at the root level. Ensure you are connected at the root level, not at the individual pluggable database (PDB) level.

66.2 DBMS_DG Security Model

The DBMS_DG package runs with invoker's rights and requires the SYSDBA privilege.

66.3 Summary of the DBMS_DG Subprogram

The DBMS_DG package contains one subprogram, the INITIATE_FS_FAILOVER procedure.

Table 66-1 DBMS_DG Package Subprogram

Subprogram	Description
INITIATE_FS_FAILOVER Procedure	Enables an application to notify either the primary or fast-start failover target standby database that a fast-start failover is necessary when the application encounters conditions that warrant a failover. This procedure can only be called while connected to a primary database or a fast-start failover standby database.

66.3.1 INITIATE_FS_FAILOVER Procedure

Use this procedure to specify a condition string that, when encountered by an application, allows the application to request that a fast-start failover be invoked.

Syntax

```
DBMS_DG.INITIATE_FS_FAILOVER (
     condstr          IN VARCHAR2)
RETURN BINARY_INTEGER;
```

Parameters

Table 66-2 INITIATE_FS_FAILOVER Procedure Parameters

Parameter	Description
condstr	Specifies the condition string for which a fast-start failover should be requested. If no condition string argument is supplied, the default string of "Application Failover Requested" will be logged in the broker log file and in the database alert log of the database on which the procedure was called.

Usage Notes

- This procedure returns a binary integer.

- Query the V$FS_FAILOVER_STATS view to see the time of the last fast-start failover and the reason it was performed.
- This procedure can only be called while connected to a primary database or a fast-start failover standby database.

Errors

Table 66-3 INITIATE_FS_FAILOVER Procedure Errors

Error	Description
ORA-00000: normal, successful completion	The request to initiate a fast-start failover has been posted to the observer.
ORA-16646: fast-start failover is disabled	Either a broker configuration does not exist or fast-start failover has not been enabled.
ORA-16666: unable to initiate fast-start failover on a bystander standby database	DBMS_DG.INITIATE_FS_FAILOVER was invoked on a bystander standby database. That is, it was not invoked on the primary or on the fast-start failover target standby database.
ORA-16817: unsynchronized fast-start failover configuration	DBMS_DG.INITIATE_FS_FAILOVER was invoked in a maximum available fast-start failover configuration when the configuration was not synchronized.
ORA-16819: fast-start failover observer not started	DBMS_DG.INITIATE_FS_FAILOVER was invoked but an observer had not yet been started.
ORA-16820: fast-start failover observer is no longer observing this database	DBMS_DG.INITIATE_FS_FAILOVER was invoked but the configuration detects that the observer may not be running.
ORA-16829: lagging fast-start failover configuration	DBMS_DG.INITIATE_FS_FAILOVER was invoked in a maximum performance fast-start failover configuration when the configuration was not in the user-specified redo lag limit.

Example

In this example, the program attempts to initiate a fast-start failover when fast-start failover is disabled. To use this example, connect as user SYS with SYDDBA privileges.

```
set serveroutput on

declare
status integer;

begin
status := dbms_dg.initiate_fs_failover(''Failover Requested'');

dbms_output.put_line(''Fast-Start Failover is disabled: Expected status = ORA-16646'');
dbms_output.put_line(''                  Actual Status = ORA-'' || status);

end;
/
exit;
```

67
DBMS_DIMENSION

DBMS_DIMENSION enables you to verify dimension relationships and provides an alternative to the Enterprise Manager Dimension Wizard for displaying a dimension definition.

> **See Also:**
>
> *Oracle Database Data Warehousing Guide* for detailed conceptual and usage information about the DBMS_DIMENSION package

This chapter contains the following topics:

- Security Model
- Summary of DBMS_DIMENSION Subprograms

67.1 DBMS_DIMENSION Security Model

Security on this package can be controlled by granting EXECUTE to selected users or roles.

A user can validate or describe all the dimensions in his own schema. To validate or describe a dimension in another schema, you must have either an object privilege on the dimension or one of the following system privileges: CREATE ANY DIMENSION, ALTER ANY DIMENSION, and DROP ANY DIMENSION.

67.2 Summary of DBMS_DIMENSION Subprograms

This table lists the DBMS_DIMENSION subprograms and briefly describes them.

Table 67-1 DBMS_DIMENSION Package Subprograms

Subprogram	Description
DESCRIBE_DIMENSION Procedure	Prints out the definition of the input dimension, including dimension owner and name, levels, hierarchies, and attributes
VALIDATE_DIMENSION Procedure	Verifies that the relationships specified in a dimension are correct

67.2.1 DESCRIBE_DIMENSION Procedure

This procedure displays the definition of the dimension, including dimension name, levels, hierarchies, and attributes. It displays the output using the DBMS_OUTPUT package.

Syntax

```
DBMS_DIMENSION.DESCRIBE_DIMENSION (
   dimension  IN VARCHAR2);
```

Parameters

Table 67-2 DESCRIBE_DIMENSION Procedure Parameter

Parameter	Description
dimension	The owner and name of the dimension in the format of owner.name.

67.2.2 VALIDATE_DIMENSION Procedure

This procedure verifies that the relationships specified in a dimension are valid. The rowid for any row that is found to be invalid will be stored in the table DIMENSION_EXCEPTIONS in the user's schema.

Syntax

```
DBMS_DIMENSION.VALIDATE_DIMENSION (
   dimension               IN VARCHAR2,
   incremental             IN BOOLEAN := TRUE,
   check_nulls             IN BOOLEAN := FALSE,
   statement_id            IN VARCHAR2 := NULL );
```

Parameters

Table 67-3 VALIDATE_DIMENSION Procedure Parameters

Parameter	Description
dimension	The owner and name of the dimension in the format of owner.name.
incremental	If TRUE, check only the new rows for tables of this dimension. If FALSE, check all the rows.
check_nulls	If TRUE, then all level columns are verified to be non-null. If FALSE, this check is omitted. Specify FALSE when non-NULLness is guaranteed by other means, such as NOT NULL constraints.
statement_id	A client-supplied unique identifier to associate output rows with specific invocations of the procedure.

68
DBMS_DISTRIBUTED_TRUST_ADMIN

DBMS_DISTRIBUTED_TRUST_ADMIN procedures maintain the Trusted Servers List. Use these procedures to define whether a server is trusted. If a database is not trusted, Oracle refuses current user database links from the database.

This chapter contains the following topics:

- Overview
- Security Model
- Examples
- Summary of DBMS_DISTRIBUTED_TRUST_ADMIN Subprograms

68.1 DBMS_DISTRIBUTED_TRUST_ADMIN Overview

Oracle uses local Trusted Servers Lists, along with enterprise domain membership lists stored in the enterprise LDAP directory service, to determine if another database is trusted. The LDAP directory service entries are managed with the Enterprise Security Manager Tool in Oracle Enterprise Manager.

Oracle considers another database to be "trusted" if it meets the following criteria:

1. It is in the same enterprise domain in the directory service as the local database.
2. The enterprise domain is marked as trusted in the directory service.
3. It is not listed as untrusted in the local Trusted Servers List. Current user database links will only be accepted from another database if both databases involved trust each other.

You can list a database server locally in the Trusted Servers List regardless of what is listed in the directory service. However, if you list a database that is not in the same domain as the local database, or if that domain is untrusted, the entry will have no effect.

This functionality is part of the Enterprise User Security feature of the Oracle Advanced Security Option.

68.2 DBMS_DISTRIBUTED_TRUST_ADMIN Security Model

To execute DBMS_DISTRIBUTED_TRUST_ADMIN, the EXECUTE_CATALOG_ROLE role must be granted to the DBA. To select from the view TRUSTED_SERVERS, the SELECT_CATALOG_ROLE role must be granted to the DBA.

It is important to know whether all servers are trusted or not trusted. Trusting a particular server with the ALLOW_SERVER procedure does not have any effect if the database already trusts all databases, or if that database is already trusted. Similarly, denying a particular server with the DENY_SERVER procedure does not have any effect if the database already does not trust any database or if that database is already untrusted.

The procedures DENY_ALL and ALLOW_ALL delete all entries (in other words, server names) that are explicitly allowed or denied using the ALLOW_SERVER procedure or DENY_SERVER procedure respectively.

68.3 DBMS_DISTRIBUTED_TRUST_ADMIN Examples

If you have not yet used the package DBMS_DISTRIBUTED_TRUST_ADMIN to change the trust listing, by default you trust all databases in the same enterprise domain if that domain it listed as trusted in the directory service:

```
SELECT * FROM TRUSTED_SERVERS;
TRUST
NAME
--------- --------------------
Trusted
All
```

Because all servers are currently trusted, you can execute the DENY_SERVER Procedure and specify that a particular server is not trusted:

```
EXECUTE DBMS_DISTRIBUTED_TRUST_ADMIN.DENY_SERVER
                            ('SALES.US.AMERICAS.ACME_AUTO.COM');
PL/SQL procedure successfully completed.

SELECT * FROM TRUSTED_SERVERS;
TRUST
NAME
--------- ------------------------------------------------
Untrusted SALES.US.AMERICAS.ACME_AUTO.COM
```

By executing the DENY_ALL Procedure, you can choose to not trust any database server:

```
EXECUTE DBMS_DISTRIBUTED_TRUST_ADMIN.DENY_ALL;

PL/SQL procedure successfully completed.

SELECT * FROM TRUSTED_SERVERS;

TRUST
NAME
--------- ------------------------------------------------
Untrusted
All
```

The ALLOW_SERVER Procedure can be used to specify that one particular database is to be trusted:

```
EXECUTE DBMS_DISTRIBUTED_TRUST_ADMIN.ALLOW_SERVER
                              ('SALES.US.AMERICAS.ACME_AUTO.COM');
PL/SQL procedure successfully completed.

SELECT * FROM TRUSTED_SERVERS;
TRUST
NAME
--------- ------------------------------------------------
Trusted   SALES.US.AMERICAS.ACME_AUTO.COM
```

68.4 Summary of DBMS_DISTRIBUTED_TRUST_ADMIN Subprograms

This table lists and briefly describes the DBMS_DISTRIBUTED_TRUST_ADMIN subprograms.

Table 68-1 ***DBMS_DISTRIBUTED_TRUST_ADMIN Package Subprograms***

Subprogram	Description
ALLOW_ALL Procedure	Empties the list and inserts a row indicating that all servers should be trusted
ALLOW_SERVER Procedure	Enables a specific server to be allowed access even though deny all is indicated in the list
DENY_ALL Procedure	Empties the list and inserts a row indicating that all servers should be untrusted
DENY_SERVER Procedure	Enables a specific server to be denied access even though allow all is indicated in the list

68.4.1 ALLOW_ALL Procedure

This procedure empties the Trusted Servers List and specifies that all servers that are members of a trusted domain in an enterprise directory service and that are in the same domain are allowed access.

The view TRUSTED_SERVERS will show "TRUSTED ALL" indicating that the database trusts all servers that are currently trusted by the enterprise directory service.

Syntax

```
DBMS_DISTRIBUTED_TRUST_ADMIN.ALLOW_ALL;
```

Usage Notes

ALLOW_ALL only applies to servers listed as trusted in the enterprise directory service and in the same enterprise domain.

68.4.2 ALLOW_SERVER Procedure

This procedure ensures that the specified server is considered trusted (even if you have previously specified "deny all").

Syntax

```
DBMS_DISTRIBUTED_TRUST_ADMIN.ALLOW_SERVER (
   server IN VARCHAR2);
```

Parameters

Table 68-2 ALLOW_SERVER Procedure Parameters

Parameter	Description
server	Unique, fully-qualified name of the server to be trusted.

Usage Notes

If the Trusted Servers List contains the entry "deny all", then this procedure adds a specification indicating that a specific database (for example, DBx) is to be trusted.

If the Trusted Servers List contains the entry "allow all", and if there is no "deny DBx" entry in the list, then executing this procedure causes no change.

If the Trusted Servers List contains the entry "allow all", and if there is a "deny DBx" entry in the list, then that entry is deleted.

68.4.3 DENY_ALL Procedure

This procedure empties the Trusted Servers List and specifies that all servers are denied access.

The view TRUSTED_SERVERS will show "UNTRUSTED ALL" indicating that no servers are currently trusted.

Syntax

```
DBMS_DISTRIBUTED_TRUST_ADMIN.DENY_ALL;
```

68.4.4 DENY_SERVER Procedure

This procedure ensures that the specified server is considered untrusted (even if you have previously specified allow all).

Syntax

```
DBMS_DISTRIBUTED_TRUST_ADMIN.DENY_SERVER (
   server IN VARCHAR2);
```

Parameters

Table 68-3 DENY_SERVER Procedure Parameters

Parameter	Description
server	Unique, fully-qualified name of the server to be untrusted.

Usage Notes

If the Trusted Servers List contains the entry allow all, then this procedure adds an entry indicating that the specified database (for example, DBx) is not to be trusted.

If the Trusted Servers List contains the entry "`deny all`", and if there is no "`allow DBx`" entry in the list, then this procedure causes no change.

If the Trusted Servers List contains the entry "`deny all`", and if there is an "`allow DBx`" entry, then this procedure causes that entry to be deleted.

69
DBMS_DNFS

The DBMS_DNFS package provides an interface to assists in creating a database using files in the backup set.

This chapter contains the following topics:

- Security Model
- Summary of DBMS_DNFS Subprograms

> **See Also:**
>
> *Oracle Database Administrator's Guide*

69.1 DBMS_DNFS Security Model

This package has to be executed by users with SYSDBA privileges.

69.2 Summary of DBMS_DNFS Subprograms

The DBMS_DNFS package includes the CLONEDB_RENAMEFILE, RESTORE_DATAFILE_PERMISSIONS, and UNMOUNTVOLUME procedures.

Table 69-1 DBMS_DNFS Package Subprograms

Subprogram	Description
CLONEDB_RENAMEFILE Procedure	Renames datafiles that were pointing to the backup set to the actual file name in cloned database.
RESTORE_DATAFILE_PERMISSIONS Procedure	This procedure will restore the file permissions for the data files belonging to the PDB to read write. PDB data files are converted to read only when one or more clones are created using this source PDB.
UNMOUNTVOLUME Procedure	This procedure cleans up the cached Direct NFS file handles in SGA.

69.2.1 CLONEDB_RENAMEFILE Procedure

This procedure is used to rename datafiles that were pointing to the backup set to the actual file name in cloned database.

The srcfile is the file name that represents the data file in the backup image copy or a read-only storage snapshot. The destfile destination file path must point to a NFS volume where cloneDB datafiles will be created. When the procedure is run successfully, the control file record is updated with the new datafile name.

Syntax

```
DBMS_DNFS.CLONEDB_RENAMEFILE (
   srcfile        IN         VARCHAR2,
   destfile       IN         VARCHAR2);
```

Parameters

Table 69-2 *CLONEDB_RENAMEFILE Procedure Parameters*

Parameter	Description
`srcfile`	Source datafile name in the control file
`destfile`	New datafile name

69.2.2 RESTORE_DATAFILE_PERMISSIONS Procedure

This procedure restores the file permissions for the data files belonging to the PDB to `read write`. PDB data files are converted to `read only` when one or more clones are created using this source PDB. This procedure must be invoked after the last clone is dropped to restore the data file permissions for the source PDB files.

Syntax

```
DBMS_DNFS.RESTORE_DATAFILE_PERMISSIONS (
   pdb_name       IN         VARCHAR2  DEFAULT NULL);
```

Parameters

Table 69-3 *RESTORE_DATAFILE_PERMISSIONS Procedure Parameters*

Parameter	Description
`pdb_name`	Name of pluggable database whose file permissions need to be restored.

69.2.3 UNMOUNTVOLUME Procedure

This procedure cleans up the cached Direct NFS file handles in SGA. This procedure must be used when any NFS mount changes are being made via the operating system and the OS unmount and mount commands are invoked.

The server is the host name or IP address of the NFS server. The volume is the exported path from the NFS server. This procedure will fail if the database has any open files in the volume that is being unmounted.

Syntax

```
DBMS_DNFS.UNMOUNTVOLUME (
   server         IN         VARCHAR2,
   volume         IN         VARCHAR2);
```

Parameters

Table 69-4 *UNMOUNTVOLUME Procedure Parameters*

Parameter	Description
`server`	NFS server host name or IP address.
`volume`	Exported path from the NFS server.

70
DBMS_DST

The DBMS_DST package provides an interface to apply the Daylight Saving Time (DST) patch to the Timestamp with Time Zone datatype.

This chapter contains the following topics:

- Overview
- Security Model
- Views
- Summary of DBMS_DST Subprograms

> **See Also:**
>
> - *Oracle Database Globalization Support Guide*
> - *Oracle Database Reference*

70.1 DBMS_DST Overview

The transition period during which Daylight Saving Time comes into effect, or stops being in effect, has the potential for problems, such as data loss, when handling timestamps with time zone data. The `DBMS_DST` package enables working with these transitions in the context of a set of rules.

70.2 DBMS_DST Security Model

The `DBMS_DST` package is an invoker's rights package.

> **See Also:**
>
> *Oracle Database PL/SQL Language Reference* for more information about using Invoker Rights or Definer Rights

The execute privilege on the package is granted to the `EXECUTE_CATALOG_ROLE` role. This role is normally granted to selected users to allow `EXECUTE` privileges for packages and procedures in the data dictionary.

The user that invokes the package must have the following privileges:

- `CREATE ANY TABLE`
- `ALTER ANY TABLE`

- DROP ANY TABLE
- SELECT ANY TABLE
- LOCK ANY TABLE
- ALTER ANY INDEX
- ALTER ANY TRIGGER
- UPDATE ANY TABLE
- EXECUTE ANY TYPE

70.3 DBMS_DST Views

The DBMS_DST package uses views to display table information.

These views are shown in the following table. They are further described in the *Oracle Database Reference*:

Table 70-1 Views used by DBMS_DST

View	Description
DBA_TSTZ_TABLES	Displays information about all tables in the database, which have columns defined on TIMESTAMP WITH TIME ZONE datatypes or object types containing attributes of TIMESTAMP WITH TIME ZONE datatypes. Its columns are the same as those in ALL_TSTZ_TABLES
USER_TSTZ_TABLES	Displays information about the tables owned by the current user, which have columns defined on TIMESTAMP WITH TIME ZONE datatypes or object types containing attributes of TIMESTAMP WITH TIME ZONE datatypes. Its columns (except for OWNER) are the same as those in ALL_TSTZ_TABLES.
ALL_TSTZ_TABLES	Displays information about the tables accessible to the current user, which have columns defined on TIMESTAMP WITH TIME ZONE datatypes or object types containing attributes of TIMESTAMP WITH TIME ZONE datatypes

70.4 Summary of DBMS_DST Subprograms

This table lists and describes the DBMS_DST package subprograms.

Table 70-2 DBMS_DST Package Subprograms

Subprogram	Description
BEGIN_PREPARE Procedure	Starts a prepare window
BEGIN_UPGRADE Procedure	Starts an upgrade window
CREATE_AFFECTED_TABLE Procedure	Creates a table that has the schema shown in the comments for the FIND_AFFECTED_TABLES Procedure

Table 70-2 (Cont.) DBMS_DST Package Subprograms

Subprogram	Description
CREATE_ERROR_TABLE Procedure	Creates a log error table
CREATE_TRIGGER_TABLE Procedure	Creates a table that is used to record active triggers disabled before performing upgrade on the table, having not been enabled due to fatal failure during the upgrading process
END_PREPARE Procedure	Ends a prepare window
END_UPGRADE Procedure	Ends an upgrade window
FIND_AFFECTED_TABLES Procedure	Finds all the tables that have affected TSTZ data due to the new timezone version
UPGRADE_DATABASE Procedure	Upgrades all tables in the database that have one or more columns defined on the TSTZ type, or an ADT containing the TSTZ type
UPGRADE_SCHEMA Procedure	Upgrades tables in a specified list of schemas that has one or more columns defined on the TSTZ type, or an ADT containing the TSTZ type
UPGRADE_TABLE Procedure	Upgrades a specified list of tables that has one or more columns defined on the TSTZ type or an ADT containing the TSTZ type

70.4.1 BEGIN_PREPARE Procedure

This procedure starts a prepare window. Once a prepare window is started successfully, the database property 'DST_UPGRADE_STATE' is set to 'PREPARE', and the database property 'SECONDARY_TT_VERSION' is set to a new timezone version.

The prepare window lets a DBA investigate data affected by the upgrade, and so judge when it is optimal to perform the upgrade. The prepare window can overlap normal database operation.

Syntax

```
DBMS_DST.BEGIN_PREPARE (
   new_version                IN  BINARY_INTEGER);
```

Parameters

Table 70-3 BEGIN_PREPARE Procedure Parameters

Parameter	Description
new_version	New timezone version to which the database is to be prepared to upgrade

70.4.2 BEGIN_UPGRADE Procedure

This procedure starts an upgrade window.

Syntax

```
DBMS_DST.BEGIN_UPGRADE (
   new_version                IN  BINARY_INTEGER,
   error_on_overlap_time      IN  BOOLEAN := FALSE,
   error_on_nonexisting_time  IN  BOOLEAN := FALSE);
```

Parameters

Table 70-4 BEGIN_UPGRADE Procedure Parameters

Parameter	Description
`new_version`	New timezone version to which the database is to be upgraded
`error_on_overlap_time`	Boolean flag indicating whether to report errors on the 'overlap' time semantic conversion error. The default is FALSE. For more information about boundary cases, see *Oracle Database SQL Language Reference*.
`error_on_nonexisting_time`	Boolean flag indicating whether to report errors on the 'non-existing' time semantic conversion error. The default value is FALSE.

70.4.3 CREATE_AFFECTED_TABLE Procedure

This procedure creates a table that has the schema shown in the comments for the FIND_AFFECTED_TABLES Procedure.

Syntax

```
DBMS_DST.CREATE_AFFECTED_TABLE (
   table_name      IN  VARCHAR2);
```

Parameters

Table 70-5 CREATE_AFFECTED_TABLE Procedure Parameters

Parameter	Description
`table_name`	Name of the table created

Usage Notes

This procedures takes a `table_name` without schema qualification, creating a table within the current user schema.

Related Topics

- FIND_AFFECTED_TABLES Procedure
  This procedure finds all the tables which have affected TSTZ data due to the new timezone version.

70.4.4 CREATE_ERROR_TABLE Procedure

This procedure creates a log error table.

The table has the following schema:

```
CREATE TABLE dst$error_table(
   table_owner     VARCHAR2(30),
   table_name      VARCHAR2(30),
   column_name     VARCHAR2(4000),
   rid             ROWID,
   error_number    NUMBER)
```

Syntax

```
DBMS_DST.CREATE_ERROR_TABLE (
   table_name      IN  VARCHAR2);
```

Parameters

Table 70-6 CREATE_ERROR_TABLE Procedure Parameters

Parameter	Description
`table_name`	Name of the table created

Usage Notes

- This procedures takes a `table_name` without schema qualification, creating a table within the current user schema.
- The error number is found when upgrading time zone file and timestamp with time zone data. For more information about error handling when upgrading time zone file and timestamp with time zone data, see Oracle Database Globalization Support Guide

70.4.5 CREATE_TRIGGER_TABLE Procedure

This procedure creates a table to record active triggers that are disabled before performing upgrade on the table, having not been enabled due to fatal failure during the upgrading process.

The table that has the following schema.

```
CREATE TABLE dst_trigger_table (
trigger_owner  VARCHAR2(30),
trigger_name   VARCHAR2(30));
```

Syntax

```
DBMS_DST.CREATE_TRIGGER_TABLE (
   table_name     IN    VARCHAR2);
```

Parameters

Table 70-7 CREATE_TRIGGER_TABLE Procedure Parameters

Parameter	Description
table_name	Name of table to be created

Usage Notes

This procedures takes a table_name without schema qualification, creating a table within the current user schema.

70.4.6 END_PREPARE Procedure

This procedure ends a prepare window.

Syntax

```
DBMS_DST.BEGIN_PREPARE;
```

70.4.7 END_UPGRADE Procedure

This procedure ends an upgrade window. An upgraded window is ended if all the affected user tables have been upgraded. Otherwise, the OUT parameter num_of_failures indicates how many tables have not been converted.

Syntax

```
DBMS_DST.END_UPGRADE (
  num_of_failures    OUT  BINARY_INTEGER);
```

Parameters

Table 70-8 END_UPGRADE Procedure Parameters

Parameter	Description
num_of_failures	Number of tables that fail to complete

70.4.8 FIND_AFFECTED_TABLES Procedure

This procedure finds all the tables which have affected TSTZ data due to the new timezone version.

This procedure can only be invoked during a prepare window. The tables which have affected TSTZ data are recorded into a table indicated by parameter affected_tables. If semantic errors must be logged, they are recorded into a table indicated by parameter log_errors_table.

Syntax

```
DBMS_DST.FIND_AFFECTED_TABLES (
   affected_tables             IN  VARCHAR2 =: 'sys.dst$affected_tables',
```

```
   log_errors                 IN  BOOLEAN := FALSE,
   log_errors_table           IN  VARCHAR2 =: 'sys.dst$error_table',
   parallel                   IN  BOOLEAN := FALSE);
```

Parameters

Table 70-9 FIND_AFFECTED_TABLES Procedure Parameters

Parameter	Description

affected_tables	Name of table with the following schema:
	`CREATE TABLE dst$affected_tables (`
	`table_owner VARCHAR2(30),`
	`table_name VARCHAR2(30),`
	`column_name VARCHAR2(4000),`
	`row_count NUMBER,`
	`error_count NUMBER)`
	The table can be created with the CREATE_AFFECTED_TABLE Procedure.

log_errors	Boolean flag indicating whether to log errors during upgrade. If FALSE, no error is logged into the log_errors_table after aborting conversion of the current table. If TRUE, the error is logged to the log_errors_table. The default is FALSE.

log_errors_table	Table name with the following schema:
	`CREATE TABLE dst$error_table (`
	`table_owner VARCHAR2(30),`
	`table_name VARCHAR2(30),`
	`column_name VARCHAR2(4000),`
	`rid ROWID,`
	`error_number NUMBER)`
	The table can be created with the CREATE_ERROR_TABLE Procedure. The rid column records the rowids of the offending rows, and the error_number column records the corresponding error number.

parallel	Boolean flag indicating whether to find the affected tables using parallel queries or serial queries. The default is FALSE.

70.4.9 UPGRADE_DATABASE Procedure

This procedure upgrades all tables in the database, which have one or more columns defined on the TSTZ type or an ADT containing the TSTZ type.

This procedure can only be invoked after an upgrade window has been started. Each table is upgraded in an atomic transaction. Note that, a base table and its materialized view log table are upgraded in an atomic transaction.

Syntax

```
DBMS_DST.UPGRADE_DATABASE  (
   num_of_failures             OUT BINARY_INTEGER,
   upgrade_data                IN  BOOLEAN := TRUE,
   parallel                    IN  BOOLEAN := FALSE,
```

```
   continue_after_errors       IN  BOOLEAN := TRUE,
   log_errors                  IN  BOOLEAN := FALSE,
   log_errors_table            IN  VARCHAR2 =: 'sys.dst$error_table' ,
   error_on_overlap_time       IN  BOOLEAN := FALSE,
   error_on_nonexisting_time   IN  BOOLEAN := FALSE,
   log_triggers_table          IN  VARCHAR2 := 'sys.dst$trigger_table');
```

Parameters

Table 70-10 UPGRADE_DATABASE Procedure Parameters

Parameter	Description
num_of_failures	Number of tables that fail to complete
upgrade_data	Boolean flag indicating whether to convert TSTZ data using the new Time Zone patch File (TRUE), or to leave it unconverted (FALSE).The default is TRUE.
parallel	Boolean flag indicating whether to convert tables using PDML (Parallel DML) or Serial DML.The default is FALSE.
continue_after_errors	Boolean flag indicating whether to continue after upgrade fails on the current table. The default is TRUE.
log_errors	Boolean flag indicating whether to log errors during upgrade. If FALSE, no error is logged into the log_errors_table after aborting conversion of the current table. If TRUE, errors are logged to the log_errors_table. The default is FALSE.

log_errors_table	Table name with the following schema:
	`CREATE TABLE dst$error_table (`
	`table_owner VARCHAR2(30),`
	`table_name VARCHAR2(30),`
	`column_name VARCHAR2(4000),`
	`rid ROWID,`
	`error_number NUMBER)`
	The table can be created with the CREATE_ERROR_TABLE Procedure. The rid column records the rowids of the offending rows, and the error_number column records the corresponding error number.

error_on_overlap_time	Boolean flag indicating whether to report errors on the 'overlap' time semantic conversion error. The default is TRUE.
error_on_nonexisting_time	Boolean flag indicating whether to report errors on the 'non-existing' time semantic conversion error. The default is TRUE.
log_triggers_table	Table to log triggers which are disabled before upgrade, having not been enabled due to a fatal failure when performing an upgrade

70.4.10 UPGRADE_SCHEMA Procedure

This procedure upgrades tables in a specified list of schemas that have one or more columns defined on the TSTZ type, or an ADT containing the TSTZ type.

This procedure can be invoked only after an upgrade window has been started. Each table is upgraded in an atomic transaction. Note that a base table and its materialized view log table are upgraded in an atomic transaction.

Syntax

```
DBMS_DST.UPGRADE_SCHEMA (
   num_of_failures             OUT BINARY_INTEGER,
   schema_list                 IN  VARCHAR2,
   upgrade_data                IN  BOOLEAN := TRUE,
   parallel                    IN  BOOLEAN := FALSE,
   continue_after_errors       IN  BOOLEAN := TRUE,
   log_errors                  IN  BOOLEAN := FALSE,
   log_errors_table            IN  VARCHAR2 =: 'sys.dst$error_table' ,
   error_on_overlap_time       IN  BOOLEAN := FALSE,
   error_on_nonexisting_time   IN  BOOLEAN := FALSE,
   log_triggers_table          IN  VARCHAR2 := 'sys.dst$trigger_table');
```

Parameters

Table 70-11 UPGRADE_SCHEMA Procedure Parameters

Parameter	Description
num_of_failures	Number of tables that fail to complete
schema_list	Schema name list (comma separated strings)
upgrade_data	Boolean flag indicating whether to convert TSTZ data using the new Time Zone patch File (TRUE) or to leave unconverted (FALSE).The default is TRUE.
parallel	Boolean flag indicating whether to convert tables using PDML (Parallel DML) or Serial DML.The default is FALSE.
continue_after_errors	Boolean flag indicating whether to continue after upgrade fails on the current table.The default is TRUE.
log_errors	Boolean flag indicating whether to log errors during upgrade. If FALSE, no error is logged into the log_errors_table after aborting conversion of the current table. If TRUE, the error is logged to the log_errors_table. The default is FALSE.

Table 70-11 (Cont.) UPGRADE_SCHEMA Procedure Parameters

Parameter	Description

log_errors_table	Table name with the following schema:
	`CREATE TABLE dst$error_table (`
	`table_owner VARCHAR2(30),`
	`table_name VARCHAR2(30),`
	`column_name VARCHAR2(4000),`
	`rid ROWID,`
	`error_number NUMBER)`
	The table can be created with the CREATE_ERROR_TABLE Procedure. The `rid` column records the rowids of the offending rows, and the `error_number` column records the corresponding error number.

error_on_overlap_time	Boolean flag indicating whether to report errors on the 'overlap' time semantic conversion error. The default is `TRUE`.
error_on_nonexisting_time	Boolean flag indicating whether to report errors on the 'non-existing' time semantic conversion error. The default is `TRUE`.
log_triggers_table	Table to log triggers that are disabled before upgrade, having not been enabled due to a fatal failure when performing an upgrade

70.4.11 UPGRADE_TABLE Procedure

This procedure upgrades a specified list of tables that have one or more columns defined on the TSTZ type, or an ADT containing the TSTZ type.

Syntax

```
DBMS_DST.UPGRADE_TABLE  (
   num_of_failures             OUT BINARY_INTEGER,
   table_list                  IN  VARCHAR2,
   upgrade_data                IN  BOOLEAN := TRUE,
   parallel                    IN  BOOLEAN := FALSE,
   continue_after_errors       IN  BOOLEAN := TRUE,
   log_errors                  IN  BOOLEAN := FALSE,
   log_errors_table            IN  VARCHAR2 =: 'sys.dst$error_table' ,
   error_on_overlap_time       IN  BOOLEAN := FALSE,
   error_on_nonexisting_time   IN  BOOLEAN := FALSE,
   log_triggers_table          IN  VARCHAR2 := 'sys.dst$trigger_table',
   atomic_upgrade              IN  BOOLEAN := FALSE);
```

Parameters

Table 70-12 UPGRADE_TABLE Procedure Parameters

Parameter	Description
num_of_failures	Number of tables that fail to complete
table_list	Table name list (comma separated strings)

Table 70-12 (Cont.) UPGRADE_TABLE Procedure Parameters

Parameter	Description
upgrade_data	Boolean flag indicating whether to convert TSTZ data using the new Time Zone patch File (TRUE), or to leave unconverted (FALSE). The default is TRUE.
parallel	Boolean flag indicating whether to convert tables using PDML (Parallel DML), or Serial DML. The default is FALSE.
continue_after_errors	Boolean flag indicating whether to continue after upgrade fails on the current table. The default is TRUE.
log_errors	Boolean flag indicating whether to log errors during upgrade. If FALSE, no error is logged into the log_errors_table after aborting conversion of the current table. If TRUE, the error is logged to the log_errors_table. The default is FALSE.

log_errors_table	Table name with the following schema:
	`CREATE TABLE dst$error_table (`
	`table_owner VARCHAR2(30),`
	`table_name VARCHAR2(30),`
	`column_name VARCHAR2(4000),`
	`rid ROWID,`
	`error_number NUMBER)`
	The table can be created with the CREATE_ERROR_TABLE Procedure. The rid parameter records the rowids of the offending rows and the corresponding error number.

error_on_overlap_time	Boolean flag indicating whether to report errors on the 'overlap' time semantic conversion error. The default is TRUE.
error_on_nonexisting_time	Boolean flag indicating whether to report errors on the 'non-existing' time semantic conversion error. The default is TRUE.
log_triggers_table	Table to log triggers that are disabled before upgrade, having not been enabled due to a fatal failure when performing an upgrade
atomic_upgrade	Boolean flag indicating whether to convert the listed tables atomically (in a single transaction). If FALSE, each table is converted in its own transaction. The default is FALSE.

Usage Notes

This procedure can only be invoked after an upgrade window has been started. The table list has to satisfy the following partial ordering:

1. If a base table has a materialized view log table, the log table must be the next item in the list.

2. If the container table for a materialized view appears in the list, the materialized view's 'non-upgraded' base tables and log tables must appear in the table list and before the container table.

A base table and its materialized view log table need to be upgraded in an atomic transaction by specifying `atomic_upgrade` to `TRUE`.

71
DBMS_EDITIONS_UTILITIES

The DBMS_EDITIONS_UTILITIES package provides helper functions for edition-related operations.

The chapter contains the following topics:

- Overview
- Security Model
- Exceptions
- Summary of DBMS_EDITIONS_UTILITIES Subprograms

71.1 DBMS_EDITIONS_UTILITIES Overview

The DBMS_EDITIONS_UTILITIES package implements an interface which provides helper functions for edition-related operations.

71.2 DBMS_EDITIONS_UTILITIES Security Model

This package is owned by SYS with execute access granted to PUBLIC. It runs with invoker's rights, that is, with the security profile of the caller.

71.3 DBMS_EDITIONS_UTILITIES Exceptions

The table in this topic lists exception messages created by DBMS_EDITIONS_UTILITIES.

Table 71-1 DBMS_EDITIONS_UTILITIES Error Messages

Error	Description
ORA-38817	Insufficient privileges
ORA-942	Missing table

71.4 Summary of DBMS_EDITIONS_UTILITIES Subprograms

This table lists and describes the DBMS_EDITIONS_UTILITIES package subprograms.

Table 71-2 DBMS_EDITIONS_UTILITIES Package Subprograms

Subprogram	Description
CLEAN_UNUSABLE_EDITIONS Procedure	Drops covered objects in unusable editions, and drops empty unusable editions if possible.

Table 71-2 (Cont.) DBMS_EDITIONS_UTILITIES Package Subprograms

Subprogram	Description
SET_EDITIONING_VIEWS_READ_ONLY Procedure	Given the schema name and table name, this procedure sets the corresponding editioning views in all editions to `READ ONLY` or `READ/WRITE`
SET_NULL_COLUMN_VALUES_TO_EXPR Procedure	For use only during an edition-based redefinition (EBR) exercise

71.4.1 CLEAN_UNUSABLE_EDITIONS Procedure

Drops all covered objects in any unusable editions and drops empty unusable editions.

The `CLEAN_UNUSABLE_EDITIONS` procedure executes immediately and in its entirety.

Syntax

```
DBMS_EDITIONS_UTILITIES.CLEAN_UNUSABLE_EDITIONS ( );
```

Usage Notes

The `COMPATIBLE` parameter must be set to 12.2.0 or higher for this procedure to execute.

> **See Also:**
>
> - *Oracle Database SQL Language Reference* for information about `DROP EDITION`
> - *Oracle Database Development Guide* for more information about using edition-based redefinition

71.4.2 SET_EDITIONING_VIEWS_READ_ONLY Procedure

Given the schema name and table name, this procedure sets the corresponding editioning views in all editions to `READ ONLY` or `READ/WRITE`.

Syntax

```
DBMS_EDITIONS_UTILITIES.SET_EDITIONING_VIEWS_READ_ONLY (
   table_name IN VARCHAR2,
   owner      IN VARCHAR2 DEFAULT NULL,
   read_only  IN BOOLEAN  DEFAULT TRUE);
```

Parameters

Table 71-3 SET_EDITIONING_VIEWS_READ_ONLY Procedure Parameters

Parameter	Description
`table_name`	Base table of the editioning views

Table 71-3 (Cont.) SET_EDITIONING_VIEWS_READ_ONLY Procedure Parameters

Parameter	Description
owner	Base table schema. The default (or NULL) is the current schema.
read_only	TRUE to set the views to read-only; FALSE (or NULL) sets the views to READ/WRITE. Default is TRUE.

Usage Notes

The user must have the following privileges:

- Owner of the table, or have the ALTER ANY TABLE system privileges
- USE object privilege on all the editions for which the views are defined

71.4.3 SET_NULL_COLUMN_VALUES_TO_EXPR Procedure

This procedure replaces NULL values in a replacement column with the value of an expression.

The expression evaluation cost is deferred to future updates and queries. The procedure is intended for use only during an edition-based redefinition (EBR) exercise.

> **See Also:**
>
> - *Oracle Database Development Guide* regarding transforming pre- to post-upgrade representation

Syntax

```
DBMS_EDITIONS_UTILITIES.SET_NULL_COLUMN_VALUES_TO_EXPR;
   table_name    IN  VARCHAR2,
   column_name   IN  VARCHAR2,
   expression    IN  VARCHAR2);
```

Parameters

Table 71-4 SET_NULL_COLUMN_VALUES_TO_EXPR Procedure Parameters

Parameter	Description
table_name	A potentially schema-qualified table name
column_name	Name of the column to be updated
expression	An expression composed of columns in the same table, constants, and SQL functions

72
DBMS_EPG

The DBMS_EPG package implements the embedded PL/SQL gateway that enables a Web browser to invoke a PL/SQL stored procedure through an HTTP listener.

This chapter contains the following topics:

- Overview
- Security Model
- Exceptions
- Data Structures
  - VARCHAR2_TABLE Table Type
- Subprogram Groups
- Summary of DBMS_EPG Subprograms

72.1 DBMS_EPG Overview

The DBMS_EPG package is a platform on which PL/SQL users develop and deploy PL/SQL Web applications. The embedded PL/SQL gateway is an embedded version of the gateway that runs in the XML database HTTP server in the Oracle database. It provides the core features of mod_plsql in the database but does not require the Oracle HTTP server powered by Apache.

In order to make a PL/SQL application accessible from a browser by way of HTTP, a Database Access Descriptor (DAD) must be created and mapped to a virtual path. A DAD is a set of configuration values used for database access and the virtual path mapping makes the application accessible under a virtual path of the XML DB HTTP Server. A DAD is represented as a servlet in XML DB HTTP Server.

72.2 DBMS_EPG Security Model

The XDBADMIN role is required to invoke the configuration interface. It may invoked by the database user "XDB".

The authorization interface can be invoked by any user.

72.3 DBMS_EPG Exceptions

The table in this topic lists the exceptions raised by the DBMS_EPG package.

Table 72-1 DBMS_EPG Exceptions

Exception	Error Code	Description
DAD_NOT_FOUND	20000	Database Access Descriptor (DAD) %s not found. Ensure that the name of the DAD is correct and that it exists.

72.4 DBMS_EPG Data Structures

The DBMS_EPG package defines a TABLE type.

VARCHAR2_TABLE Table Type

This type is used by the procedures GET_ALL_GLOBAL_ATTRIBUTES, GET_ALL_DAD_ATTRIBUTES, GET_ALL_DAD_MAPPINGS, and GET_DAD_LIST to return lists of attribute names, attribute values, virtual paths, and database access descriptors (DAD).

```
TYPE VARCHAR2_TABLE IS TABLE OF VARCHAR2(4000) INDEX BY BINARY_INTEGER;
```

72.5 DBMS_EPG Subprogram Groups

The DBMS_EPG consists of two interfaces: configuration subprograms and authorization subprograms.

- Configuration Subprograms
- Authorization Subprograms

72.5.1 DBMS_EPG Configuration Subprograms

The Configuration subprogram group contain the subprogram interfaces to examine and modify the global and database access descriptor (DAD) specific settings of the embedded PL/SQL gateway.

Table 72-2 Configuration Subprogram Group

Subprogram	Description
CREATE_DAD Procedure	Creates a new DAD
DELETE_DAD_ATTRIBUTE Procedure	Deletes a DAD attribute
DELETE_GLOBAL_ATTRIBUTE Procedure	Deletes a global attribute
DROP_DAD Procedure	Drops a DAD
GET_ALL_DAD_ATTRIBUTES Procedure	Retrieves all the attributes of a DAD.
GET_ALL_DAD_MAPPINGS Procedure	Retrieves all virtual paths to which the specified DAD is mapped.
GET_ALL_GLOBAL_ATTRIBUTES Procedure	Retrieves all global attributes and values
GET_DAD_ATTRIBUTE Function	Retrieves the value of a DAD attribute

Table 72-2 (Cont.) Configuration Subprogram Group

Subprogram	Description
GET_DAD_LIST Procedure	Retrieves a list of all DADs for an Embedded Gateway instance.
GET_GLOBAL_ATTRIBUTE Function	Retrieves the value of a global attribute
MAP_DAD Procedure	Maps a DAD to the specified virtual path.
SET_DAD_ATTRIBUTE Procedure	Sets the value for a DAD
SET_GLOBAL_ATTRIBUTE Procedure	Sets the value of a global attribute
UNMAP_DAD Procedure	Unmaps a DAD from the specified virtual path

72.5.2 DBMS_EPG Authorization Subprograms

The Authorization subprogram group contains the subprogram interfaces to authorize and deauthorize the use of a database user's privileges by the embedded PL/SQL gateway through a specific database access descriptor (DAD)

Table 72-3 Authorization Subprogram Group

Subprogram	Description
AUTHORIZE_DAD Procedure	Authorizes a DAD to invoke procedures and access document tables with a database user's privileges
DEAUTHORIZE_DAD Procedure	Deauthorizes a DAD with regard to invoking procedures and accessing document tables with a database user's privileges

72.6 Summary of DBMS_EPG Subprograms

This table lists the `DBMS_ALERT` subprograms and briefly describes them.

Table 72-4 DBMS_EPG Package Subprograms

Subprogram	Description
AUTHORIZE_DAD Procedure	authorizes a DAD to invoke procedures and access document tables with a database user's privileges
CREATE_DAD Procedure	Creates a new DAD
DEAUTHORIZE_DAD Procedure	Deauthorizes a DAD with regard to invoking procedures and accessing document tables with a database user's privileges
DELETE_DAD_ATTRIBUTE Procedure	Deletes a DAD attribute
DELETE_GLOBAL_ATTRIBUTE Procedure	Deletes a global attribute
DROP_DAD Procedure	Drops a DAD
GET_ALL_DAD_ATTRIBUTES Procedure	Retrieves all the attributes of a DAD.
GET_ALL_DAD_MAPPINGS Procedure	Retrieves all virtual paths to which the specified DAD is mapped.

Table 72-4 (Cont.) DBMS_EPG Package Subprograms

Subprogram	Description
GET_ALL_GLOBAL_ATTRIBUTES Procedure	Retrieves all global attributes and values
GET_DAD_ATTRIBUTE Function	Retrieves the value of a DAD attribute
GET_DAD_LIST Procedure	Retrieves a list of all DADs for an Embedded Gateway instance.
GET_GLOBAL_ATTRIBUTE Function	Retrieves the value of a global attribute
MAP_DAD Procedure	Maps a DAD to the specified virtual path.
SET_DAD_ATTRIBUTE Procedure	Sets the value for a DAD
SET_GLOBAL_ATTRIBUTE Procedure	Sets the value of a global attribute
UNMAP_DAD Procedure	Unmaps a DAD from the specified virtual path

72.6.1 AUTHORIZE_DAD Procedure

This procedure authorizes a DAD to invoke procedures and access document tables with a database user's privileges. The invoker can always authorize the use of her/his own privileges.

> **See Also:**
>
> Authorization Subprograms for other subprograms in this group

Syntax

```
DBMS_EPG.AUTHORIZE_DAD (
   dad_name  IN  VARCHAR2,
   path      IN  VARCHAR2 DEFAULT NULL);
```

Parameters

Table 72-5 AUTHORIZE_DAD Procedure Parameters

Parameter	Description
dad_name	The name of the DAD to create
user	The user whose privileges to deauthorize. If use, the invoker is assumed.

Usage Notes

- To authorize the use of another user's privileges, the invoker must have the ALTER USER system privilege.
- The DAD must exist but its "database-username" DAD attribute does not have to be set to user to authorize.
- Multiple users can authorize the same DAD and it is up to the DAD's "database-username" setting to decide which user's privileges to use.

Exceptions

Raises an error if the DAD or user does not exist, or the invoker does not have the needed system privilege.

Examples

```
DBMS_EPG.AUTHORIZE_DAD('HR');
```

72.6.2 CREATE_DAD Procedure

This procedure creates a new DAD.

> **See Also:**
>
> Configuration Subprograms for other subprograms in this group

Syntax

```
DBMS_EPG.CREATE_DAD (
   dad_name  IN  VARCHAR2,
   path      IN  VARCHAR2 DEFAULT NULL);
```

Parameters

Table 72-6 CREATE_DAD Procedure Parameters

Parameter	Description
dad_name	The name of the DAD to create
path	The virtual path to which to map the DAD

72.6.3 DEAUTHORIZE_DAD Procedure

This procedure deauthorizes a DAD with regard to invoking procedures and accessing document tables with a database user's privileges. The invoker can always deauthorize the use of his own privileges.

> **See Also:**
>
> Authorization Subprograms for other subprograms in this group

Syntax

```
DBMS_EPG.DEAUTHORIZE_DAD (
   dad_name  IN  VARCHAR2,
   path      IN  VARCHAR2 DEFAULT NULL);
```

Parameters

Table 72-7 DEAUTHORIZE_DAD Procedure Parameters

Parameter	Description
dad_name	The name of the DAD for which to deauthorize use
user	The user whose privileges to deauthorize. If use, the invoker is assumed.

Usage Notes

To deauthorize the use of another user's privileges, the invoker must have the ALTER USER system privilege.

Exceptions

Raises an error if the DAD or user does not exist, or the invoker does not have the needed system privilege.

Examples

```
DBMS_EPG.DEAUTHORIZE_DAD('HR');
```

72.6.4 DELETE_DAD_ATTRIBUTE Procedure

This procedure deletes a DAD attribute.

> **See Also:**
>
> Configuration Subprograms for other subprograms in this group

Syntax

```
DBMS_EPG.DELETE_DAD_ATTRIBUTE (
   dad_name      IN  VARCHAR2,
   attr_name     IN  VARCHAR2);
```

Parameters

Table 72-8 DELETE_DAD_ATTRIBUTE Procedure Parameters

Parameter	Description
dad_name	The name of the DAD for which to delete a DAD attribute
attr_name	The name of the DAD attribute to delete

Exceptions

Raises an error if DAD does not exist

72.6.5 DELETE_GLOBAL_ATTRIBUTE Procedure

This procedure deletes a global attribute.

> **See Also:**
>
> Configuration Subprograms for other subprograms in this group

Syntax

```
DBMS_EPG.DELETE_GLOBAL_ATTRIBUTE (
   attr_name     IN  VARCHAR2);
```

Parameters

Table 72-9 DELETE_GLOBAL_ATTRIBUTE Procedure Parameters

Parameter	Description
attr_name	The global attribute to delete

72.6.6 DROP_DAD Procedure

This procedure drops a DAD. All the virtual-path mappings of the DAD will be dropped also.

> **See Also:**
>
> Configuration Subprograms for other subprograms in this group

Syntax

```
DBMS_EPG.DROP_DAD (
   dadname  IN  VARCHAR2);
```

Parameters

Table 72-10 DROP_DAD Procedure Parameters

Parameter	Description
dad_name	The DAD to drop

Exceptions

Raises an error if the DAD does not exist.

72.6.7 GET_ALL_DAD_ATTRIBUTES Procedure

This procedure retrieves all the attributes of a DAD. The outputs are 2 correlated index-by tables of the name/value pairs.

> **See Also:**
>
> Configuration Subprograms for other subprograms in this group

Syntax

```
DBMS_EPG.GET_ALL_DAD_ATTRIBUTES (
   dad_name      IN          VARCHAR2,
   attr_names    OUT NOCOPY  VARCHAR2_TABLE,
   attr_values   OUT NOCOPY  VARCHAR2_TABLE);
```

Parameters

Table 72-11 GET_ALL_DAD_ATTRIBUTES Procedure Parameters

Parameter	Description
dad_names	The name of the DAD
attr_names	The attribute names
attr_values	The attribute values

Exceptions

Raises an error if DAD does not exist.

Usage Notes

If the DAD has no attributes set, then `attr_names` and `attr_values` will be set to empty arrays.

72.6.8 GET_ALL_DAD_MAPPINGS Procedure

This procedure retrieves all the virtual paths to which the specified DAD is mapped.

> **See Also:**
>
> Configuration Subprograms for other subprograms in this group

Syntax

```
DBMS_EPG.GET_ALL_DAD_MAPPINGS (
   dad_name      IN          VARCHAR2,
   paths         OUT NOCOPY  VARCHAR2_TABLE);
```

Parameters

Table 72-12 GET_ALL_DAD_MAPPINGS Procedure Parameters

Parameter	Description
dad_names	The name of the DAD
paths	The virtual paths to which h the DAD is mapped

Exceptions

Raises an error if DAD does not exist.

Usage Notes

If the DAD is not mapped to any virtual path, paths will be set to empty arrays.

72.6.9 GET_ALL_GLOBAL_ATTRIBUTES Procedure

This procedure retrieves all global attributes and values. The outputs are 2 correlated index-by tables of the name/value pairs.

> **See Also:**
>
> Configuration Subprograms for other subprograms in this group

Syntax

```
DBMS_EPG.GET_ALL_GLOBAL_ATTRIBUTES (
   attr_names     OUT   NOCOPY  VARCHAR2_TABLE,
   attr_values    OUT   NOCOPY  VARCHAR2_TABLE);
```

Parameters

Table 72-13 GET_ALL_GLOBAL_ATTRIBUTES Procedure Parameters

Parameter	Description
attr_names	The global attribute names
attr_values	The values of the global attributes

Usage Notes

If the gateway instance has no global attributes set, then attr_names and attr_values will be set to empty arrays.

72.6.10 GET_DAD_ATTRIBUTE Function

This procedure retrieves the value of a DAD attribute.

> **See Also:**
>
> Configuration Subprograms for other subprograms in this group

Syntax

```
DBMS_EPG.GET_DAD_ATTRIBUTE (
   dad_name     IN  VARCHAR2,
   attr_name    IN  VARCHAR2)
 RETURN VARCHAR2;
```

Parameters

Table 72-14 GET_DAD_ATTRIBUTE Function Parameters

Parameter	Description
`dad_name`	The name of the DAD for which to delete an attribute
`attr_name`	The name of the attribute to delete

Return values

Returns the DAD attribute value. Returns `NULL` if attribute is unknown or has not been set.

Exceptions

Raises an error if DAD does not exist.

72.6.11 GET_DAD_LIST Procedure

This procedure retrieves a list of all DADs for an Embedded Gateway instance.

> **See Also:**
>
> Configuration Subprograms for other subprograms in this group

Syntax

```
DBMS_EPG.GET_DAD_LIST (
   dad_names     OUT NOCOPY  VARCHAR2_TABLE);
```

Parameters

Table 72-15 GET_DAD_LIST Procedure Parameters

Parameter	Description
dad_names	The list of all DADs

Usage Notes

If no DADs exist then dad_names will be set to an empty array.

72.6.12 GET_GLOBAL_ATTRIBUTE Function

This function retrieves the value of a global attribute.

> **See Also:**
>
> Configuration Subprograms for other subprograms in this group

Syntax

```
DBMS_EPG.GET_GLOBAL_ATTRIBUTE (
   attr_name  IN  VARCHAR2)
 RETURN VARCHAR2;
```

Parameters

Table 72-16 GET_GLOBAL_ATTRIBUTE Procedure Parameters

Parameter	Description
attr_name	The global attribute to retrieve

Return Values

Returns the global attribute value. Returns NULL if attribute has not been set or is not a valid attribute.

72.6.13 MAP_DAD Procedure

This procedure maps a DAD to the specified virtual path. If the virtual path exists already, the old virtual-path mapping will be overridden.

> **See Also:**
>
> Configuration Subprograms for other subprograms in this group

Syntax

```
DBMS_EPG.MAP_DAD (
   dad_name  IN  VARCHAR2,
   path      IN  VARCHAR2);
```

Parameters

Table 72-17 MAP_DAD Procedure Parameters

Parameter	Description
dad_name	The name of the DAD to map
path	The virtual path to map

Exceptions

Raises and error if the DAD does not exist.

72.6.14 SET_DAD_ATTRIBUTE Procedure

This procedure sets the value for a DAD.

> **See Also:**
>
> Configuration Subprograms for other subprograms in this group

Syntax

```
DBMS_EPG.SET_DAD_ATTRIBUTE (
   dad_name    IN  VARCHAR2,
   attr_name   IN  VARCHAR2,   attr_value  IN  VARCHAR2);
```

Parameters

Table 72-18 SET_DAD_ATTRIBUTE Procedure Parameters

Parameter	Description
dad_name	The name of the DAD for which to set the attribute
attr_name	The name of the attribute to set
attr_value	The attribute value to set

Table 72-19 Mapping Between mod_plsql and Embedded PL/SQL Gateway DAD Attributes

mod_plsql DAD Attribute	Embedded PL/SQL Gateway DAD Attribute	Allows Multiple Occurr-ences	Legal Values
PlsqlAfterProcedure	after-procedure	No	String
PlsqlAlwaysDescribeProcedure	always-describe-procedure	No	Enumeration of On, Off
PlsqlAuthenticationMode	authentication-mode	No	Enumeration of Basic, SingleSignOn, GlobalOwa, CustomOwa, PerPackageOwa
PlsqlBeforeProcedure	before-procedure	No	String
PlsqlBindBucketLengths	bind-bucket-lengths	Yes	Unsigned integer
PlsqlBindBucketWidths	bind-bucket-widths	Yes	Unsigned integer
PlsqlCGIEnvironmentList	cgi-environment-list	Yes	String
PlsqlCompatibilityMode	compatibility-mode	No	Unsigned integer
PlsqlDatabaseUsername	database-username	No	String
PlsqlDefaultPage	default-page	No	String
PlsqlDocumentPath	document-path	No	String
PlsqlDocumentProcedure	document-procedure	No	String
PlsqlDocumentTablename	document-table-name	No	String
PlsqlErrorStyle	error-style	No	Enumeration of ApacheStyle, ModplsqlStyle, DebugStyle
PlsqlExclusionList	exclusion-list	Yes	String
PlsqlFetchBufferSize	fetch-buffer-size	No	Unsigned integer
PlsqlInfoLogging	info-logging	No	Enumeration of InfoDebug
PlsqlOWADebugEnable	owa-debug-enable	No	Enumeration of On, Off
PlsqlMaxRequestsPerSession	max-requests-per-session	No	Unsigned integer
PlsqlNLSLanguage	nls-language	No	String
PlsqlPathAlias	path-alias	No	String
PlsqlPathAliasProcedure	path-alias-procedure	No	String
PlsqlRequestValidationFunction	request-validation-function	No	String
PlsqlSessionCookieName	session-cookie-name	No	String

Table 72-19 (Cont.) Mapping Between mod_plsql and Embedded PL/SQL Gateway DAD Attributes

mod_plsql DAD Attribute	Embedded PL/SQL Gateway DAD Attribute	Allows Multiple Occurr-ences	Legal Values
PlsqlSessionStateManagement	session-state-management	No	Enumeration of StatelessWithResetPackageState, StatelessWithFastRestPackageState, StatelessWithPreservePackageState
PlsqlTransferMode	transfer-mode	No	Enumeration of Char, Raw
PlsqlUploadAsLongRaw	upload-as-long-raw	No	String

Exceptions

Raises an error if DAD does not exist or the attribute is unknown.

Usage Notes

- If `attr_name` attribute has been set before, then the old value will be overwritten with the new `attr_value` argument.
- The embedded gateway assumes default values when the attributes are not set. The default values of the DAD attributes should be sufficient for most users of the embedded gateway. mod_plsql users should note the following
  - The `PlsqlDatabasePassword` attribute is not needed.
  - The `PlsqlDatabaseConnectString` attribute is not needed because the embedded gateway does not support logon to external databases.

Examples

```
DBMS_EPG.SET_DAD_ATTRIBUTE('HR', 'default-page', 'HRApp.home');
```

72.6.15 SET_GLOBAL_ATTRIBUTE Procedure

This procedure sets the value of a global attribute.

> **See Also:**
>
> Configuration Subprograms for other subprograms in this group

Syntax

```
DBMS_EPG.SET_GLOBAL_ATTRIBUTE (
   attr_name    IN VARCHAR2,
   attr_value   IN VARCHAR2);
```

Parameters

Table 72-20 SET_GLOBAL_ATTRIBUTE Procedure Parameters

Parameter	Description
attr_name	The global attribute to set
attr_value	The attribute value to set

Table 72-21 Mapping Between mod_plsql and Embedded PL/SQL Gateway Global Attributes

mod_plsql Global Attribute	Embedded PL/SQL Gateway Global Attribute	Allows Multiple Occurr-ences	Legal Values
PlsqlLogLevel	log-level	No	Unsigned integer
PlsqlMaxParameters	max-parameters	No	Unsigned integer

Usage Notes

- The attribute name is case sensitive. The value may or may not be case-sensitive depending on the attribute.
- If attr_name attribute has been set before, then the old value will be overwritten with the new attr_value argument.

Exceptions

Raises an error if the attribute is unknown.

Examples

```
dbms_epg.set_global_attribute('max-parameters', '100');
```

72.6.16 UNMAP_DAD Procedure

This procedure unmaps a DAD from the specified virtual path. If path is NULL, the procedure removes all virtual-path mappings for the DAD but keeps the DAD.

> **See Also:**
>
> Configuration Subprograms for other subprograms in this group

Syntax

```
DBMS_EPG.UNMAP_DAD (
   dad_name IN VARCHAR2,
   path     IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 72-22 UNMAP_DAD Procedure Parameters

Parameter	Description
dad_name	The name of the DAD to unmap
path	The virtual path to unmap

Usage Notes

Raises and error if the DAD does not exist.

73
DBMS_ERRLOG

The DBMS_ERRLOG package provides a procedure that enables you to create an error logging table so that DML operations can continue after encountering errors rather than abort and roll back. This enables you to save time and system resources.

This chapter contains the following topics:

- Security Model
- Summary of DBMS_ERRLOG Subprograms

> **See Also:**
>
> *Oracle Database Data Warehousing Guide* for more information regarding how to use DBMS_ERRLOG and *Oracle Database SQL Language Reference* for error_logging_clause syntax

73.1 DBMS_ERRLOG Security Model

Security on this package can be controlled by granting EXECUTE on this package to selected users or roles. The EXECUTE privilege is granted publicly. However, to create an error logging table, you need SELECT access on the base table or view, the CREATE TABLE privilege, as well as tablespace quota for the target tablespace.

73.2 Summary of DBMS_ERRLOG Subprograms

The DBMS_ERRORLOG package includes the CREATE_ERROR_LOG procedure subprogram.

Table 73-1 DBMS_ERRLOG Package Subprograms

Subprogram	Description
CREATE_ERROR_LOG Procedure	Creates the error logging table used in DML error logging

73.2.1 CREATE_ERROR_LOG Procedure

This procedure creates the error logging table needed to use the DML error logging capability.

LONG, CLOB, BLOB, BFILE, and ADT datatypes are not supported in the columns.

Syntax

```
DBMS_ERRLOG.CREATE_ERROR_LOG (
   dml_table_name            IN VARCHAR2,
   err_log_table_name        IN VARCHAR2 := NULL,
   err_log_table_owner       IN VARCHAR2 := NULL,
   err_log_table_space       IN VARCHAR2 := NULL,
   skip_unsupported          IN BOOLEAN := FALSE);
```

Parameters

Table 73-2 CREATE_ERROR_LOG Procedure Parameters

Parameter	Description
dml_table_name	The name of the DML table to base the error logging table on. The name can be fully qualified (for example, emp, scott.emp, "EMP", "SCOTT"."EMP"). If a name component is enclosed in double quotes, it will not be upper cased.
err_log_table_name	The name of the error logging table you will create. The default is the first 25 characters in the name of the DML table prefixed with 'ERR$_'. Examples are the following: dml_table_name: 'EMP', err_log_table_name: 'ERR$_EMP' dml_table_name: '"Emp2"', err_log_table_name: 'ERR$_Emp2'
err_log_table_owner	The name of the owner of the error logging table. You can specify the owner in dml_table_name. Otherwise, the schema of the current connected user is used.
err_log_table_space	The tablespace the error logging table will be created in. If not specified, the default tablespace for the user owning the DML error logging table will be used.
skip_unsupported	When set to TRUE, column types that are not supported by error logging will be skipped over and not added to the error logging table. When set to FALSE, an unsupported column type will cause the procedure to terminate. The default is FALSE.

Examples

First, create an error log table for the channels table in the SH schema, using the default name generation.

Then, see all columns of the table channels:

```
SQL> DESC channels
Name                                      Null?       Type
----------------------------              -------     -----
CHANNEL_ID                                NOT NULL    CHAR(1)
CHANNEL_DESC                              NOT NULL    VARCHAR2(20)
CHANNEL_CLASS                                         VARCHAR2(20)
```

Finally, see all columns of the generated error log table. Note the mandatory control columns that are created by the package:

```
SQL> DESC ERR$_CHANNELS
Name                           Null?    Type
-----------------              ----     ----
ORA_ERR_NUMBER$                         NUMBER
ORA_ERR_MESG$                           VARCHAR2(2000)
ORA_ERR_ROWID$                          ROWID
ORA_ERR_OPTYP$                          VARCHAR2(2)
ORA_ERR_TAG$                            VARCHAR2(2000)
CHANNEL_ID                              VARCHAR2(4000)
CHANNEL_DESC                            VARCHAR2(4000)
CHANNEL_CLASS                           VARCHAR2(4000)
```

See *Oracle Database Administrator's Guide* for more information regarding control columns.

74
DBMS_FGA

The DBMS_FGA package provides fine-grained security functions.

This chapter contains the following topics:

- Security Model
- Operational Notes
- Summary of DBMS_FGA Subprograms

74.1 DBMS_FGA Security Model

You must have the AUDIT_ADMIN role or the EXECUTE privilege on the DBMS_FGA package to create audit policies. DBMS_FGA is an invoker rights package.

To analyze and audit data, you must have the AUDIT_VIEWER role. Because the audit function can potentially capture all user environment and application context values, policy administration should be executable by privileged users only. The policy event handler module is executed with the module owner's privilege.

74.2 DBMS_FGA Operational Notes

This package is available for only cost-based optimization. The rule-based optimizer may generate unnecessary audit records since audit monitoring can occur before row filtering.

For both the rule-based optimizer and the cost-based optimizer, you can query the SQL_TEXT and SQL_BINDS columns of the UNIFIED_AUDIT_TRAIL view to analyze the SQL text and corresponding bind variables that are issued.

74.3 Summary of DBMS_FGA Subprograms

This table lists the DBMS_FGA subprograms and briefly describes them.

Table 74-1 ***DBMS_FGA Package Subprograms***

Subprogram	Description
ADD_POLICY Procedure	Creates an audit policy using the supplied predicate as the audit condition
DISABLE_POLICY Procedure	Disables an audit policy
DROP_POLICY Procedure	Drops an audit policy
ENABLE_POLICY Procedure	Enables an audit policy

74.3.1 ADD_POLICY Procedure

This procedure creates an audit policy using the supplied predicate as the audit condition.

Syntax

```
DBMS_FGA.ADD_POLICY(
   object_schema      IN  VARCHAR2 DEFAULT NULL,
   object_name        IN  VARCHAR2,
   policy_name        IN  VARCHAR2,
   audit_condition    IN  VARCHAR2 DEFAULT NULL,
   audit_column       IN  VARCHAR2 DEFAULT NULL,
   handler_schema     IN  VARCHAR2 DEFAULT NULL,
   handler_module     IN  VARCHAR2 DEFAULT NULL,
   enable             IN  BOOLEAN DEFAULT TRUE,
   statement_types    IN  VARCHAR2 DEFAULT SELECT,
   audit_trail        IN  BINARY_INTEGER DEFAULT NULL,
   audit_column_opts  IN  BINARY_INTEGER DEFAULT ANY_COLUMNS,
   policy_owner       IN  VARCHAR2 DEFAULT NULL);
```

Parameters

Table 74-2 ADD_POLICY Procedure Parameters

Parameter	Description
object_schema	Schema of the object to be audited. If NULL, the current schema is assumed.
object_name	Name of the object to be audited
policy_name	Unique name of the policy. Do not enter special characters such as spaces or commas. If you want to use special characters for the policy name, then enclose the name in quotation marks.
audit_condition	A condition in a row that indicates a monitoring condition. NULL is allowed and acts as TRUE.
audit_column	Columns to be checked for access. These can include OLS hidden columns or object type columns. The default, NULL, causes audit if any column is accessed or affected.
handler_schema	Schema that contains the event handler. The default, NULL, causes the current schema to be used.
handler_module	Function name of the event handler; includes the package name if necessary. This function is invoked only after the first row that matches the audit condition in the query is processed. If the procedure fails with an exception, the user SQL statement will fail as well.
enable	Enables the policy if TRUE, which is the default
statement_types	SQL statement types to which this policy is applicable: INSERT, UPDATE, DELETE, or SELECT only
audit_trail	In an environment that has not yet migrated to unified auditing, the destination (DB or XML) of fine-grained audit records. Also specifies whether to populate the LSQLTEXT and LSQLBIND columns in the FGA_LOG$ system table.

Table 74-2 (Cont.) ADD_POLICY Procedure Parameters

Parameter	Description
audit_column_opts	Establishes whether a statement is audited when the query references *any* column specified in the audit_column parameter or only when *all* such columns are referenced
policy_owner	User who owns the fine-grained auditing policy. However, this setting is not a user-supplied argument. The Oracle Data Pump client uses this setting internally to recreate the fine-grained audit policies appropriately.

Usage Notes

- A table or view can have a maximum of 256 fine-grained audit policies applied to it.
- If object_schema is not specified, the current schema is assumed.
- An FGA policy should not be applied to out-of-line columns such as LOB columns.
- Each audit policy is applied to the query individually. However, at most one audit record may be generated for each policy, no matter how many rows being returned satisfy that policy's audit_condition. In other words, whenever any number of rows being returned satisfy an audit condition defined on the table, a single audit record will be generated for each such policy.
- If a table with an FGA policy defined on it receives a Fast Path insert or a vectored update, the hint is automatically disabled before any such operations. Disabling the hint allows auditing to occur according to the policy's terms. (One example of a Fast Path insert is the statement INSERT-WITH-APPEND-hint.)
- The audit_condition must be a boolean expression that can be evaluated using the values in the row being inserted, updated, or deleted. The expression can also use functions, such as the USER or SYS_CONTEXT functions.

  The expression must not combine conditions using operators such as AND and OR. audit_condition can be NULL (or omitted), which is interpreted as TRUE, but it cannot contain the following elements:

  – Subqueries or sequences
  – The following attributes of the USERENV namespace when accessed using the SYS_CONTEXT function:
    * CURRENT_SQL
    * CURRENT_SQL_LENGTH
    * CURRENT_BIND
  – Any use of the pseudo columns LEVEL, PRIOR, or ROWNUM.

  Specifying an audit condition of "1=1" to force auditing of all specified statements ("statement_types") affecting the specified column ("audit_column") is no longer needed to achieve this purpose. A NULL value for audit_condition causes audit to happen even if no rows are processed, so that all actions on a table with this policy are audited.
- The audit_condition is evaluated using the privileges of the user who creates the policy.
- For the audit_condition setting, do not include functions, which execute the auditable statement on the same base table, in the audit_condition setting. For example,

suppose you create a function that executes an INSERT statement on the HR.EMPLOYEES table. The policy audit_condition contains this function and it is for INSERT statements (as set by the statement_types parameter). When the policy is used, the function executes recursively until the system has run out of memory. This can raise the error ORA-1000: maximum open cursors exceeded or ORA-00036: maximum number of recursive SQL levels (50) exceeded.

- Do not issue the DBMS_FGA.ENABLE_POLICY or DBMS_FGA.DISABLE_POLICY statement from a policy function in a condition.
- The audit function (handler_module) is an alerting mechanism for the administrator. The required interface for such a function is as follows:

  ```
  PROCEDURE fname ( object_schema VARCHAR2, object_name VARCHAR2, policy_name
  VARCHAR2 )  AS ...
  ```

  where *fname* is the name of the procedure, *object_schema* is the name of the schema of the table audited, *object_name* is the name of the table to be audited, and *policy_name* is the name of the policy being enforced. The audit function will be executed with the function owner's privilege.
- If you have migrated to unified auditing, then omit the audit_trail parameter because the audit records will automatically be written to the unified audit trail.
- Be aware that sensitive data, such as credit card information, can be recorded in clear text.
- The audit_trail parameter, if used, specifies both where the fine-grained audit trail will be written and whether it is to include the query's SQL Text and SQL Bind variable information (typically in columns named LSQLTEXT and LSQLBIND):
  - If audit_trail includes XML, then fine-grained audit records are written to XML-format operating system files stored in the directory specified by an AUDIT_FILE_DEST statement in SQL. (The default AUDIT_FILE_DEST is $ORACLE_BASE/admin/$DB_UNIQUE_NAME/adump on Unix-based systems, and $ORACLE_BASE\admin\$DB_UNIQUE_NAME\adump on Windows systems.)
  - If audit_trail includes DB instead, then the audit records are written to the SYS.FGA_LOG$ table in the database. However, for read-only databases, Oracle Database writes the fine-grained audit records to XML files, regardless of the audit_trail settings.
  - If audit_trail includes EXTENDED, then the query's SQL Text and SQL Bind variable information are included in the audit trail.
  - For example:
    - Setting audit_trail to DBMS_FGA.DB sends the audit trail to the SYS.FGA_LOG$ table in the database and omits SQL Text and SQL Bind.
    - Setting audit_trail to DBMS_FGA.DB + DBMS_FGA.EXTENDED sends the audit trail to the SYS.FGA_LOG$ table in the database and includes SQL Text and SQL Bind.
    - Setting audit_trail to DBMS_FGA.XML writes the audit trail in XML files sent to the operating system and omits SQL Text and SQL Bind.
    - Setting audit_trail to DBMS_FGA.XML + DBMS_FGA.EXTENDED writes the audit trail in XML files sent to the operating system and includes SQL Text and SQL Bind.

  The audit_trail parameter appears in the ALL_AUDIT_POLICIES view.

- You can change the operating system destination using the following command:

  ```
  ALTER SYSTEM SET AUDIT_FILE_DEST =  New Directory DEFERRED
  ```

- On many platforms, XML audit files are named *process_name_processId*.xml, for example, ora_2111.xml. Alternatively,l on Windows, the XML audit files are named *process_name_ThreadId*.xml (or *process_name_ProcessId*.xml if the process is not running as a thread).
- The audit_column_opts parameter establishes whether a statement is audited
  - when the query references *any* column specified in the audit_column parameter (audit_column_opts = DBMS_FGA.ANY_COLUMNS), or
  - only when *all* such columns are referenced (audit_column_opts = DBMS_FGA.ALL_COLUMNS).

  The default is DBMS_FGA.ANY_COLUMNS.

  The ALL_AUDIT_POLICIES view also shows audit_column_opts.
- When audit_column_opts is set to DBMS_FGA.ALL_COLUMNS, a SQL statement is audited only when all the columns mentioned in audit_column have been explicitly referenced in the statement. And these columns must be referenced in the same SQL-statement or in the sub-select.

  All these columns must refer to a single table/view or alias.

  If a SQL statement selects the columns from different table aliases, the statement will not be audited.
- Every XML audit record contains the elements AUDIT_TYPE and EXTENDED_TIMESTAMP, with the latter printed in UTC zone (with no timezone information). Values retrieved using V$XML_AUDIT_TRAIL view are converted to session timezone and printed.
- For SQL_TEXT and SQL_BIND element values (CLOB type columns), the dynamic view shows only the first 4000 characters. The underlying XML file may have more than 4000 characters for such SQL_TEXT and SQL_BIND values.
- For large numbers of XML audit files, querying V$XML_AUDIT_TRAIL is faster when they are loaded into a database table using SQL*Loader or a similar tool. XML audit files are larger than the equivalent written to OS files when AUDIT_TRAIL=OS.
- Error handling is the same as when AUDIT_TRAIL=OS. If any error occurs in writing an audit record to disk, including the directory identified by AUDIT_FILE_DEST being full, the auditing operation fails. An alert message is logged.
- The policy event handler module will be executed with the module owner's privilege.
- Do not create recursive fine-grained audit handlers. For example, suppose you create a handler that executes an INSERT statement on the HR.EMPLOYEES table. The policy that is associated with this handler is for INSERT statements (as set by the statement_types parameter). When the policy is used, the handler executes recursively until the system has run out of memory. This can raise the error ORA-1000: maximum open cursors exceeded or ORA-00036: maximum number of recursive SQL levels (50) exceeded. See also *Oracle Database Security Guide* with regard to Creating a Fine-Grained Audit Policy.
- The fine-grained audit handler module should not have explicit COMMIT, ROLLBACK, and DDL statements mentioned in it.
- The values for the audit_trail parameter (XML and XML+EXTENDED) cause fine-grained auditing records to be written to operating system files in XML format. A dynamic view,

V$XML_AUDIT_TRAIL, makes such audit records from XML files available to DBAs through SQL query, providing enhanced usability. Querying this view causes all XML files (all files with an .xml extension) in the AUDIT_FILE_DEST directory to be parsed and presented in relational table format.

Audit records stored in operating system files can be more secure than database-stored audit records because access can require file permissions that DBAs do not have. Operating system storage for audit records also offers higher availability, since such records remain available even if the database is temporarily inaccessible.

The DBA_COMMON_AUDIT_TRAIL view includes the contents of the V$XML_AUDIT_TRAIL dynamic view for standard and fine-grained audit records.

Note that the V$XML_AUDIT_TRAIL view is populated only if unified auditing is not enabled. If you have enabled unified auditing, then you can query the UNIFIED_AUDIT_TRAIL data dictionary view for the audit trail records.

See Also:

Oracle Database Security Guide for an example of creating an email alert handler for a fine-grained audit policy

Examples

```
DBMS_FGA.ADD_POLICY (
   object_schema      =>  'scott',
   object_name        =>  'emp',
   policy_name        =>  'mypolicy1',
   audit_condition    =>  'sal < 100',
   audit_column       =>  'comm,sal',
   handler_schema     =>   NULL,
   handler_module     =>   NULL,
   enable             =>   TRUE,
   statement_types    =>  'INSERT, UPDATE',
   audit_column_opts  =>   DBMS_FGA.ANY_COLUMNS,
   policy_owner       =>  'sec_admin);
```

74.3.2 DISABLE_POLICY Procedure

This procedure disables an audit policy.

Syntax

```
DBMS_FGA.DISABLE_POLICY(
   object_schema  IN  VARCHAR2,
   object_name    IN  VARCHAR2,
   policy_name    IN  VARCHAR2);
```

Parameters

Table 74-3 DISABLE_POLICY Procedure Parameters

Parameter	Description
object_schema	Schema of the object to be audited. If NULL, the current schema is assumed.
object_name	Name of the object to be audited
policy_name	Unique name of the policy

The default value for object_schema is NULL. If NULL, the current schema is assumed.

Examples

```
DBMS_FGA.DISABLE_POLICY (
object_schema   =>  'scott',
object_name     =>  'emp',
policy_name     =>  'mypolicy1');
```

74.3.3 DROP_POLICY Procedure

This procedure drops an audit policy.

Syntax

```
DBMS_FGA.DROP_POLICY(
   object_schema  IN  VARCHAR2,
   object_name    IN  VARCHAR2,
   policy_name    IN  VARCHAR2);
```

Parameters

Table 74-4 DROP_POLICY Procedure Parameters

Parameter	Description
object_schema	Schema of the object to be audited. If NULL, the current schema is assumed.
object_name	Name of the object to be audited
policy_name	Unique name of the policy

Usage Notes

The DBMS_FGA procedures cause current DML transactions, if any, to commit before the operation unless they are inside a DDL event trigger. With DDL transactions, the DBMS_FGA procedures are part of the DDL transaction. The default value for object_schema is NULL. If NULL, the current schema is assumed.

> **Note:**
>
> Oracle Database automatically drops the audit policy if you remove the object specified in the `object_name` parameter of the `DBMS_FGA.ADD_POLICY` procedure, or if you drop the user who created the audit policy.

Examples

```
DBMS_FGA.DROP_POLICY (
object_schema   =>  'scott',
object_name     =>  'emp',
policy_name     =>  'mypolicy1');
```

74.3.4 ENABLE_POLICY Procedure

This procedure enables an audit policy.

Syntax

```
DBMS_FGA.ENABLE_POLICY(
   object_schema  IN  VARCHAR2,
   object_name    IN  VARCHAR2,
   policy_name    IN  VARCHAR2,
   enable         IN  BOOLEAN);
```

Parameters

Table 74-5 ENABLE_POLICY Procedure Parameters

Parameter	Description
`object_schema`	Schema of the object to be audited. If `NULL`, the current schema is assumed.
`object_name`	Name of the object to be audited
`policy_name`	Unique name of the policy
`enable`	Defaults to `TRUE` to enable the policy

Examples

```
DBMS_FGA.ENABLE_POLICY (
object_schema    =>  'scott',
object_name      =>  'emp',
policy_name      =>  'mypolicy1',
enable           =>   TRUE);
```

75
DBMS_FILE_GROUP

The DBMS_FILE_GROUP package, one of a set of Oracle Streams packages, provides administrative interfaces for managing file groups, file group versions, and files. A file group repository is a collection of all of the file groups in a database and can contain multiple versions of a particular file group. You can use this package to create and manage file group repositories.

This chapter contains the following topics:

- Overview
- Security Model
- Constants
- Summary of DBMS_FILE_GROUP Subprograms

75.1 DBMS_FILE_GROUP Overview

It is helpful to understand terminology before using the DBMS_FILE_GROUP package.

The following terms pertain to the DBMS_FILE_GROUP package:

File

A **file** is a reference to a file stored on hard disk. A file is composed of a file name, a directory object, and a file type. The directory object references the directory in which the file is stored on hard disk. For example, a file might have the following components:

- The file name is expdat.dmp.
- The directory object that contains the file is db_files.
- The file type is DBMS_FILE_GROUP.EXPORT_DUMP_FILE.

Version

A **version** is a collection of related files. For example, a version might consist of a set of data files and a Data Pump export dump file generated by a Data Pump transportable tablespace export. Only one Data Pump export dump file is allowed in a version.

File Group

A **file group** is a collection of versions. A file group can logically group a set of versions. For example, a file group named financial_quarters can keep track of quarterly financial data by logically grouping versions of files related to a tablespace set. The tablespaces containing the data can be exported at the end of each quarter and versioned under names such as Q1FY04, Q2FY04, and so on.

75.2 DBMS_FILE_GROUP Security Model

There are two ways to define control on the DBMS_FILE_GROUP package.

- Granting EXECUTE on this package to selected users or roles.
- Granting EXECUTE_CATALOG_ROLE to selected users or roles.

If subprograms in the package are run from within a stored procedure, then the user who runs the subprograms must be granted EXECUTE privilege on the package directly. It cannot be granted through a role.

75.3 DBMS_FILE_GROUP Constants

The DBMS_FILE_GROUP package defines several enumerated constants for specifying parameter values. Enumerated constants must be prefixed with the package name. For example, DBMS_FILE_GROUP.EXPORT_DUMP_FILE.

The following table lists the parameters and enumerated constants.

Table 75-1 DBMS_FILE_GROUP Parameters with Enumerated Constants

Parameter	Option	Type	Description
file_type new_file_type	• DATAFILE • EXPORT_DUMP_FILE • DATAPUMP_LOG_FILE	VARCHAR2(30)	DATAFILE is a datafile for a database. This constant can be specified as 'DATAFILE'. EXPORT_DUMP_FILE is a Data Pump export dump file. This constant can be specified as 'DUMPSET'. DATAPUMP_LOG_FILE is a Data Pump export log file. This constant can be specified as 'DATAPUMPLOG'.
max_versions retention_days	• INFINITE	NUMBER	INFINITE specifies no limit. The max_versions or retention_days can increase without reaching a limit.

Table 75-1 (Cont.) DBMS_FILE_GROUP Parameters with Enumerated Constants

Parameter	Option	Type	Description
privilege	System privilege specified in the GRANT_SYSTEM_PRIVILEGE procedure: • READ_ANY_FILE_GROUP • MANAGE_ANY_FILE_GROUP • MANAGE_FILE_GROUP Object privilege specified in the GRANT_OBJECT_PRIVILEGE procedure: • READ_ON_FILE_GROUP • MANAGE_ON_FILE_GROUP	BINARY_INTEGER	READ_ANY_FILE_GROUP grants the privilege to view information about any file group in any schema in the data dictionary. MANAGE_ANY_FILE_GROUP grants the privilege to create, manage, and drop any file group in any schema. MANAGE_FILE_GROUP grants the privilege to create, manage, and drop file groups in the user's schema. READ_ON_FILE_GROUP grants the privilege to view information about a specific file group in the data dictionary. MANAGE_ON_FILE_GROUP grants the privilege to manage a specific file group in a schema other than the user's schema.

75.4 Summary of DBMS_FILE_GROUP Subprograms

This table lists the DBMS_FILE_GROUP subprograms and briefly describes them.

Table 75-2 DBMS_FILE_GROUP Package Subprograms

Subprogram	Description
ADD_FILE Procedure	Adds a file to a version of a file group
ALTER_FILE Procedure	Alters a file in a version of a file group
ALTER_FILE_GROUP Procedure	Alters a file group
ALTER_VERSION Procedure	Alters a version of a file group
CREATE_FILE_GROUP Procedure	Creates a file group
CREATE_VERSION Procedure	Creates a version of a file group
DROP_FILE_GROUP Procedure	Drops a file group
DROP_VERSION Procedure	Drops a version of a file group
GRANT_OBJECT_PRIVILEGE Procedure	Grants object privileges on a file group to a user
GRANT_SYSTEM_PRIVILEGE Procedure	Grants system privileges for file group operations to a user
PURGE_FILE_GROUP Procedure	Purges a file group using the file group's retention policy
REMOVE_FILE Procedure	Removes a file from a version of a file group
REVOKE_OBJECT_PRIVILEGE Procedure	Revokes object privileges on a file group from a user
REVOKE_SYSTEM_PRIVILEGE Procedure	Revokes system privileges for file group operations from a user

> **Note:**
>
> All subprograms commit unless specified otherwise.

75.4.1 ADD_FILE Procedure

This procedure adds a file to a version of a file group.

Syntax

```
DBMS_FILE_GROUP.ADD_FILE(
  file_group_name  IN  VARCHAR2,
  file_name        IN  VARCHAR2,
  file_type        IN  VARCHAR2  DEFAULT NULL,
  file_directory   IN  VARCHAR2  DEFAULT NULL,
  version_name     IN  VARCHAR2  DEFAULT NULL,
  comments         IN  VARCHAR2  DEFAULT NULL);
```

Parameters

Table 75-3 ADD_FILE Procedure Parameters

Parameter	Description
`file_group_name`	The name of the file group that contains the version, specified as *`[schema_name.]file_group_name`*. For example, if the schema is `hq_dba` and the file group name is `sales_tbs`, then specify `hq_dba.sales_tbs`. If the schema is not specified, then the current user is the default.
`file_name`	The name of the file being added to the version. Each file name in a version must be unique.

`file_type`	The file type. The following are reserved file types:
	• If the file is a datafile, then enter the following:
	`'DATAFILE'`
	• If the file is a Data Pump export dump file, then enter the following:
	`'DUMPSET'`
	Data Pump metadata is populated when a Data Pump export dump file is imported.
	• If the file is a Data Pump export log file, then enter the following:
	`'DATAPUMPLOG'`
	If the file type is not one of the reserved file types, then either enter a text description of the file type, or specify `NULL` to omit a file type description.
	See "Constants" for more information about the reserved file types.

Table 75-3 (Cont.) ADD_FILE Procedure Parameters

Parameter	Description
`file_directory`	The name of the directory object that corresponds to the directory containing the file. If `NULL`, then the procedure uses the default directory object for the version. If `NULL` and no default directory object exists for the version, then the procedure uses the default directory object for the file group. If `NULL` and no default directory object exists for the version or file group, then the procedure raises an error.
`version_name`	The name of the version to which the file is added. If a positive integer is specified as a `VARCHAR2` value, then the integer is interpreted as a version number. For example, if `'1'` is specified, then the file is added to version 1 of the file group. If `NULL`, then the procedure uses the version with the latest creation time for the file group.
`comments`	Comments about the file being added

Usage Notes

To run this procedure with either `DBMS_FILE_GROUP.EXPORT_DUMP_FILE` or `'DUMPSET'` specified for the `file_type` parameter, a user must meet the following requirements:

- Have the appropriate privileges to import the Data Pump export dump file
- Have `READ` privilege on the directory object that contains the Data Pump export dump file

> **See Also:**
>
> *Oracle Database Utilities* for more information about Data Pump privileges

75.4.2 ALTER_FILE Procedure

This procedure alters a file in a version of a file group.

Syntax

```
DBMS_FILE_GROUP.ALTER_FILE(
  file_group_name     IN  VARCHAR2,
  file_name           IN  VARCHAR2,
  version_name        IN  VARCHAR2  DEFAULT NULL,
  new_file_name       IN  VARCHAR2  DEFAULT NULL,
  new_file_directory  IN  VARCHAR2  DEFAULT NULL,
  new_file_type       IN  VARCHAR2  DEFAULT NULL,
  remove_file_type    IN  VARCHAR2  DEFAULT 'N',
  new_comments        IN  VARCHAR2  DEFAULT NULL,
  remove_comments     IN  VARCHAR2  DEFAULT 'N');
```

Parameters

Table 75-4 ALTER_FILE Procedure Parameters

Parameter	Description
file_group_name	The name of the file group that contains the version, specified as *[schema_name.]file_group_name*. For example, if the schema is hq_dba and the file group name is sales_tbs, then specify hq_dba.sales_tbs. If the schema is not specified, then the current user is the default.
file_name	The name of the file being altered in the version
version_name	The name of the version that contains the file being altered. If a positive integer is specified as a VARCHAR2 value, then the integer is interpreted as a version number. For example, if '1' is specified, then the file in version 1 of the file group is altered. If NULL, then the procedure uses the version with the latest creation time for the file group.
new_file_name	The new name of the file if the file name is being changed. Each file name in a version must be unique. If NULL, then the procedure does not change the file name. **Note:** When a non-NULL new file name is specified, this procedure changes the metadata for the file name in the data dictionary, but it does not change the file name on the hard disk.
new_file_directory	The new name of the directory object that corresponds to the directory containing the file, if the directory object is being changed. If NULL, then the procedure does not change the directory object name. **Note:** When a non-NULL new file directory is specified, this procedure changes the metadata for the file directory in the data dictionary, but it does not change the file directory on the hard disk.
new_file_type	The file type. The following are reserved file types: • If the file is a datafile, then enter the following: 'DATAFILE' • If the file is a Data Pump export dump file, then enter the following: 'DUMPSET' • If the file is a Data Pump export log file, then enter the following: 'DATAPUMPLOG' If the file type is not one of the reserved file types, then enter a text description of the file type. If NULL, then the procedure does not change the file type. **See Also:** "Constants" for more information about the reserved file types.
remove_file_type	If Y, then the procedure removes the file type. If Y and the new_file_type parameter is non-NULL, then the procedure raises an error. If N, then the procedure does not remove the file type.

Table 75-4 (Cont.) ALTER_FILE Procedure Parameters

Parameter	Description
new_comments	New comments about the file being altered. If non-NULL, then the procedure replaces the existing comments with the specified comments. If NULL, then the procedure does not change the existing comments.
remove_comments	If Y, then the procedure removes the comments for the file. If Y and the new_comments parameter is non-NULL, then the procedure raises an error. If N, then the procedure does not change the existing comments.

Usage Notes

If the file type is changed to DBMS_FILE_GROUP.EXPORT_DUMP_FILE or 'DUMPSET', then Data Pump metadata for the file is populated. If the file type is changed from DBMS_FILE_GROUP.EXPORT_DUMP_FILE or 'DUMPSET', then Data Pump metadata for the file is purged.

To run this procedure with DBMS_FILE_GROUP.EXPORT_DUMP_FILE or 'DUMPSET' specified for the new_file_type parameter, a user must meet the following requirements:

- Have the appropriate privileges to import the Data Pump export dump file
- Have READ privilege on the directory object that contains the Data Pump export dump file

> **See Also:**
>
> *Oracle Database Utilities* for more information about Data Pump privileges

75.4.3 ALTER_FILE_GROUP Procedure

This procedure alters a file group.

Syntax

```
DBMS_FILE_GROUP.ALTER_FILE_GROUP(
  file_group_name           IN  VARCHAR2,
  keep_files                IN  VARCHAR2  DEFAULT NULL,
  min_versions              IN  NUMBER    DEFAULT NULL,
  max_versions              IN  NUMBER    DEFAULT NULL,
  retention_days            IN  NUMBER    DEFAULT NULL,
  new_default_directory     IN  VARCHAR2  DEFAULT NULL,
  remove_default_directory  IN  VARCHAR2  DEFAULT 'N',
  new_comments              IN  VARCHAR2  DEFAULT NULL,
  remove_comments           IN  VARCHAR2  DEFAULT 'N');
```

Parameters

Table 75-5 ALTER_FILE_GROUP Procedure Parameters

Parameter	Description
file_group_name	The name of the file group being altered, specified as *[schema_name.]file_group_name*. For example, if the schema is hq_dba and the file group name is sales_tbs, then specify hq_dba.sales_tbs. If the schema is not specified, then the current user is the default.
keep_files	If Y, then the files in the file group are retained on hard disk if the file group or a version of the file group is dropped or purged. If N, then the files in the file group are deleted from hard disk if the file group or a version of the file group is dropped or purged. If NULL, then this parameter is not changed. **Note:** If the file group is dropped because of a DROP USER CASCADE statement, then the setting of this parameter determines whether the files are dropped from the hard disk.
min_versions	The minimum number of versions to retain. The specified value must be greater than or equal to 1. If NULL, then the procedure does not change the min_versions setting for the file group.
max_versions	The maximum number of versions to retain. The specified value must be greater than or equal to the value specified for min_versions. When the number of versions exceeds the specified max_versions, the oldest version is purged. Specify DBMS_FILE_GROUP.INFINITE for no limit to the number of versions. If NULL, then the procedure does not change the max_versions setting for the file group.
retention_days	The maximum number of days to retain a version. The specified value must be greater than or equal to 0 (zero). When the age of a version exceeds the specified retention_days and there are more versions than the number specified in min_versions, the version is purged. The age of a version is calculated by subtracting the creation time from the current time. A decimal value can specify a fraction of a day. For example, 1.25 specifies one day and six hours. Specify DBMS_FILE_GROUP.INFINITE for no limit to the number of days a version can exist. If NULL, then the procedure does not change the retention_days setting for the file group.
new_default_directory	The default directory object used when files are added to a file group if no directory is specified when the files are added, and no default directory object is specified for the version. If NULL, then the procedure does not change the default directory.

Table 75-5 (Cont.) ALTER_FILE_GROUP Procedure Parameters

Parameter	Description
remove_default_directory	If Y, then the procedure removes the default directory for the file group. If Y and the new_default_directory parameter is set to a non-NULL value, then the procedure raises an error. If N, then the procedure does not remove the default directory for the file group.
new_comments	Comments about the file group. If non-NULL, then the new comments replace the existing comments for the file group. If NULL, then the procedure does not change the existing comments.
remove_comments	If Y, then the comments for the file group are removed. If Y and the new_comments parameter is set to a non-NULL value, then the procedure raises an error. If N, then the procedure does not change the comments for the file group.

Usage Notes

If min_versions is set to 1, then the only version of the file group can be purged when a new version is added. If the addition of the new version is not complete when the existing version is purged, then there can be a period of time when no version of the file group is available. Therefore, set min_versions to at least 2 if a version of the file group must be available at all times.

75.4.4 ALTER_VERSION Procedure

This procedure alters a version of a file group.

Syntax

```
DBMS_FILE_GROUP.ALTER_VERSION(
  file_group_name           IN  VARCHAR2,
  version_name              IN  VARCHAR2  DEFAULT NULL,
  new_version_name          IN  VARCHAR2  DEFAULT NULL,
  remove_version_name       IN  VARCHAR2  DEFAULT 'N',
  new_default_directory     IN  VARCHAR2  DEFAULT NULL,
  remove_default_directory  IN  VARCHAR2  DEFAULT 'N',
  new_comments              IN  VARCHAR2  DEFAULT NULL,
  remove_comments           IN  VARCHAR2  DEFAULT 'N');
```

Parameters

Table 75-6 ALTER_VERSION Procedure Parameters

Parameter	Description
file_group_name	The name of the file group that contains the version, specified as *[schema_name.]file_group_name*. For example, if the schema is hq_dba and the file group name is sales_tbs, then specify hq_dba.sales_tbs. If the schema is not specified, then the current user is the default.
version_name	The name of the version being altered. If a positive integer is specified as a VARCHAR2 value, then the integer is interpreted as a version number. For example, if '1' is specified, then version 1 of the file group is altered. If '*' is specified, then the procedure alters all versions, and the new_version_name parameter must be NULL. If NULL, then the procedure uses the version with the latest creation time for the file group.
new_version_name	The new name of the version. Do not specify a schema. The specified version name cannot be a positive integer or an asterisk ('*'). If NULL, then the procedure does not change the version name.
remove_version_name	If Y, then the procedure removes the version name. If the version name is removed, then the version number must be used to manage the version. If Y and the new_version_name parameter is set to a non-NULL value, then the procedure raises an error. If N, then the procedure does not remove the version name.
new_default_directory	The default directory object used when files are added to a version if no directory is specified when the files are added. If NULL, then the procedure does not change the default directory.
remove_default_directory	If Y, then the procedure removes the default directory. If Y and the new_default_directory parameter is set to a non-NULL value, then the procedure raises an error. If N, then the procedure does not remove the default directory.
new_comments	Comments about the version. If non-NULL, then the new comments replace the existing comments for the version. If NULL, then the procedure does not change the comments.
remove_comments	If Y, then the procedure removes the comments for the version. If Y and the new_comments parameter is set to a non-NULL value, then the procedure raises an error. If N, then the procedure does not remove the comments for the version.

75.4.5 CREATE_FILE_GROUP Procedure

This procedure creates a file group.

Syntax

```
DBMS_FILE_GROUP.CREATE_FILE_GROUP(
  file_group_name    IN  VARCHAR2,
  keep_files         IN  VARCHAR2  DEFAULT 'Y',
  min_versions       IN  NUMBER    DEFAULT 2,
  max_versions       IN  NUMBER    DEFAULT DBMS_FILE_GROUP.INFINITE,
  retention_days     IN  NUMBER    DEFAULT DBMS_FILE_GROUP.INFINITE,
  default_directory  IN  VARCHAR2  DEFAULT NULL,
  comments           IN  VARCHAR2  DEFAULT NULL);
```

Parameters

Table 75-7 CREATE_FILE_GROUP Procedure Parameters

Parameter	Description
`file_group_name`	The name of the file group, specified as *`[schema_name.]file_group_name`*. For example, if the schema is `hq_dba` and the file group name is `sales_tbs`, then specify `hq_dba.sales_tbs`. If the schema is not specified, then the current user is the default.
`keep_files`	If `Y`, then the files in the file group are retained on hard disk if the file group or a version of the file group is dropped or purged. If `N`, then the files in the file group are deleted from hard disk if the file group or a version of the file group is dropped or purged. **Note:** If the file group is dropped because of a `DROP USER CASCADE` statement, then the setting of this parameter determines whether the files are dropped from the hard disk.
`min_versions`	The minimum number of versions to retain. The specified value must be greater than or equal to `1`.
`max_versions`	The maximum number of versions to retain. The specified value must be greater than or equal to the value specified for `min_versions`. When the number of versions exceeds the specified `max_versions`, the oldest version is purged. Specify `DBMS_FILE_GROUP.INFINITE` for no limit to the number of versions.
`retention_days`	The maximum number of days to retain a version. The specified value must be greater than or equal to `0` (zero). When the age of a version exceeds the specified `retention_days` and there are more versions than the number specified in `min_versions`, the version is purged. The age of a version is calculated by subtracting the creation time from the current time. A decimal value can specify a fraction of a day. For example, `1.25` specifies one day and six hours. Specify `DBMS_FILE_GROUP.INFINITE` for no limit to the number of days a version can exist.
`default_directory`	The default directory object used when files are added to a file group if no directory is specified when the files are added, and no default directory object is specified for the version.

Table 75-7 (Cont.) CREATE_FILE_GROUP Procedure Parameters

Parameter	Description
comments	Comments about the file group being created.

Usage Notes

If min_versions is set to 1, then the only version of the file group can be purged when a new version is added. If the addition of the new version is not complete when the existing version is purged, then there can be a period of time when no version of the file group is available. Therefore, set min_versions to at least 2 if a version of the file group must be available at all times.

75.4.6 CREATE_VERSION Procedure

This procedure creates a version of a file group.

This procedure automatically runs the PURGE_FILE_GROUP procedure. Therefore, versions can be purged based on the file group's retention policy.

This procedure is overloaded. One version of the procedure contains the OUT parameter version_out, and the other does not.

Syntax

```
DBMS_FILE_GROUP.CREATE_VERSION(
  file_group_name    IN  VARCHAR2,
  version_name       IN  VARCHAR2 DEFAULT NULL,
  default_directory  IN  VARCHAR2 DEFAULT NULL,
  comments           IN  VARCHAR2 DEFAULT NULL);

DBMS_FILE_GROUP.CREATE_VERSION(
  file_group_name    IN   VARCHAR2,
  version_name       IN   VARCHAR2 DEFAULT NULL,
  default_directory  IN   VARCHAR2 DEFAULT NULL,
  comments           IN   VARCHAR2 DEFAULT NULL,
  version_out        OUT  VARCHAR2);
```

Parameters

Table 75-8 CREATE_VERSION Procedure Parameters

Parameter	Description
file_group_name	The name of the file group to which the new version is added, specified as *[schema_name.]file_group_name*. For example, if the schema is hq_dba and the file group name is sales_tbs, then specify hq_dba.sales_tbs. If the schema is not specified, then the current user is the default.
version_name	The name of the version being created. Do not specify a schema. The specified version name cannot be a positive integer because, when a version is created, a version number is generated automatically. The specified version name cannot be an asterisk ('*').

Table 75-8 (Cont.) CREATE_VERSION Procedure Parameters

Parameter	Description
`default_directory`	The default directory object used when files are added to a version if no directory is specified when the files are added.
`comments`	Comments about the version being created
`version_out`	If the `version_name` parameter is set to a non-`NULL` value, then this parameter contains the specified version name. If the `version_name` parameter is set to `NULL`, then this parameter contains the generated version number.

See Also:

PURGE_FILE_GROUP Procedure

75.4.7 DROP_FILE_GROUP Procedure

This procedure drops a file group.

Syntax

```
DBMS_FILE_GROUP.DROP_FILE_GROUP(
  file_group_name  IN  VARCHAR2,
  keep_files       IN  VARCHAR2  DEFAULT NULL);
```

Parameters

Table 75-9 DROP_FILE_GROUP Procedure Parameters

Parameter	Description
`file_group_name`	The name of the file group being dropped, specified as *`[schema_name.]file_group_name`*. For example, if the schema is `hq_dba` and the file group name is `sales_tbs`, then specify `hq_dba.sales_tbs`. If the schema is not specified, then the current user is the default.
`keep_files`	If `Y`, then the procedure retains the files in the file group on hard disk. If `N`, then the procedure deletes the files in the file group from hard disk. If `NULL`, then the procedure uses the default keep files property of the file group.

Usage Notes

If this procedure deletes files on hard disk, then the user who runs the procedure must have `WRITE` privilege on the directory object that contains the files.

75.4.8 DROP_VERSION Procedure

This procedure drops a version of a file group.

Syntax

```
DBMS_FILE_GROUP.DROP_VERSION(
  file_group_name  IN  VARCHAR2,
  version_name     IN  VARCHAR2 DEFAULT NULL,
  keep_files       IN  VARCHAR2 DEFAULT NULL);
```

Parameters

Table 75-10 DROP_VERSION Procedure Parameters

Parameter	Description
`file_group_name`	The name of the file group that contains the version, specified as *`[schema_name.]file_group_name`*. For example, if the schema is `hq_dba` and the file group name is `sales_tbs`, then specify `hq_dba.sales_tbs`. If the schema is not specified, then the current user is the default.
`version_name`	The name of the version being dropped. If a positive integer is specified as a VARCHAR2 value, then the integer is interpreted as a version number. For example, if `'1'` is specified, then version 1 of the file group is dropped. If `NULL`, then the procedure uses the version with the oldest creation time for the file group. If `'*'`, then the procedure drops all versions.
`keep_files`	If `Y`, then the procedure retains the files in the version on hard disk. If `N`, then the procedure deletes the files in the version from hard disk. If `NULL`, then the procedure uses the default keep files property of the file group.

Usage Notes

If this procedure deletes files on hard disk, then the user who runs the procedure must have `WRITE` privilege on the directory object that contains the files.

75.4.9 GRANT_OBJECT_PRIVILEGE Procedure

This procedure grants object privileges on a file group to a user.

Syntax

```
DBMS_FILE_GROUP.GRANT_OBJECT_PRIVILEGE(
  object_name   IN  VARCHAR2,
  privilege     IN  BINARY_INTEGER,
  grantee       IN  VARCHAR2,
  grant_option  IN  BOOLEAN DEFAULT FALSE);
```

Parameters

Table 75-11 GRANT_OBJECT_PRIVILEGE Procedure Parameters

Parameter	Description
`object_name`	The name of the file group on which the privilege is granted, specified as *`[schema_name.]file_group_name`*. For example, if the schema is `hq_dba` and the file group name is `sales_tbs`, then specify `hq_dba.sales_tbs`. If the schema is not specified, then the current user is the default.
`privilege`	The constant that specifies the privilege. See "Constants" for valid privileges.
`grantee`	The name of the user or role for which the privilege is granted. The specified user cannot be the owner of the object.
`grant_option`	If `TRUE`, then the specified user granted the specified privilege can grant this privilege to others. If `FALSE`, then the specified user granted the specified privilege cannot grant this privilege to others.

Usage Notes

To run this procedure, a user must meet at least one of the following requirements:

- Be the owner of the object on which the privilege is granted
- Have the same privilege as the privilege being granted with the grant option

75.4.10 GRANT_SYSTEM_PRIVILEGE Procedure

This procedure grants system privileges for file group operations to a user.

Syntax

```
DBMS_FILE_GROUP.GRANT_SYSTEM_PRIVILEGE(
  privilege     IN  BINARY_INTEGER,
  grantee       IN  VARCHAR2,
  grant_option  IN  BOOLEAN  DEFAULT FALSE);
```

Parameters

Table 75-12 GRANT_SYSTEM_PRIVILEGE Procedure Parameters

Parameter	Description
`privilege`	The constant that specifies the privilege. See "Constants" for valid privileges.
`grantee`	The name of the user or role for which the privilege is granted. The user who runs the procedure cannot be specified.
`grant_option`	If `TRUE`, then the specified user granted the specified privilege can grant this privilege to others. If `FALSE`, then the specified user granted the specified privilege cannot grant this privilege to others.

75.4.11 PURGE_FILE_GROUP Procedure

This procedure purges a file group using the file group's retention policy.

A file group's retention policy is determined by its settings for the `max_versions`, `min_versions`, and `retention_days` parameters. The following versions of a file group are removed when a file group is purged:

- All versions greater than the `max_versions` setting for the file group when versions are ordered in descending order by creation time. Therefore, the older versions are purged before the newer versions.
- All versions older than the `retention_days` setting for the file group unless purging a version would cause the number of versions to drop below the `min_versions` setting for the file group.

A job named `SYS.FGR$AUTOPURGE_JOB` automatically purges all file groups in a database periodically according to the job's schedule. You can adjust this job's schedule using the `DBMS_SCHEDULER` package. Alternatively, you can create a job that runs the `PURGE_FILE_GROUP` procedure periodically.

Syntax

```
DBMS_FILE_GROUP.PURGE_FILE_GROUP(
  file_group_name  IN  VARCHAR2);
```

Parameter

Table 75-13 PURGE_FILE_GROUP Procedure Parameter

Parameter	Description
`file_group_name`	The name of the file group, specified as *`[schema_name.]file_group_name`*. For example, if the schema is `hq_dba` and the file group name is `sales_tbs`, then specify `hq_dba.sales_tbs`. If the schema is not specified, then the current user is the default. If `NULL` and this procedure is run by SYS user, then the procedure purges all file groups.

Usage Notes

If this procedure deletes files on hard disk, then the user who runs the procedure must have `WRITE` privilege on the directory object that contains the files. Files are deleted when a version is purged and the `keep_files` parameter is set to `N` for the version's file group.

75.4.12 REMOVE_FILE Procedure

This procedure removes a file from a version of a file group.

Syntax

```
DBMS_FILE_GROUP.REMOVE_FILE(
  file_group_name  IN  VARCHAR2,
  file_name        IN  VARCHAR2,
```

```
  version_name     IN  VARCHAR2 DEFAULT NULL,
  keep_file        IN  VARCHAR2 DEFAULT NULL);
```

Parameters

Table 75-14 REMOVE_FILE Procedure Parameters

Parameter	Description
`file_group_name`	The name of the file group that contains the version, specified as *`[schema_name.]file_group_name`*. For example, if the schema is `hq_dba` and the file group name is `sales_tbs`, then specify `hq_dba.sales_tbs`. If the schema is not specified, then the current user is the default.
`file_name`	The name of the file being removed from the version
`version_name`	The name of the version from which the file is removed. If a positive integer is specified as a VARCHAR2 value, then the integer is interpreted as a version number. For example, if `'1'` is specified, then the file is removed from version 1 of the file group. If `NULL`, then the procedure uses the version with the latest creation time for the file group. If `'*'`, then the procedure removes the file from all versions.
`keep_file`	If `Y`, then the procedure retains the file on hard disk. If `N`, then the procedure deletes the file from hard disk. If `NULL`, then the procedure uses the default keep files property of the file group.

Usage Notes

If this procedure deletes files on hard disk, then the user who runs the procedure must have `WRITE` privilege on the directory object that contains the files.

75.4.13 REVOKE_OBJECT_PRIVILEGE Procedure

This procedure revokes object privileges on a file group from a user.

Syntax

```
DBMS_FILE_GROUP.REVOKE_OBJECT_PRIVILEGE(
  object_name  IN  VARCHAR2,
  privilege    IN  BINARY_INTEGER,
  revokee      IN  VARCHAR2);
```

Parameters

Table 75-15 REVOKE_OBJECT_PRIVILEGE Procedure Parameters

Parameter	Description
`object_name`	The name of the file group on which the privilege is revoked, specified as *`[schema_name.]file_group_name`*. For example, if the schema is `hq_dba` and the file group name is `sales_tbs`, then specify `hq_dba.sales_tbs`. If the schema is not specified, then the current user is the default.
`privilege`	The constant that specifies the privilege. See "Constants" for valid privileges.

Table 75-15 (Cont.) REVOKE_OBJECT_PRIVILEGE Procedure Parameters

Parameter	Description
revokee	The name of the user or role from which the privilege is revoked. The user who owns the object cannot be specified.

75.4.14 REVOKE_SYSTEM_PRIVILEGE Procedure

This procedure revokes system privileges for file group operations from a user.

Syntax

```
DBMS_FILE_GROUP.REVOKE_SYSTEM_PRIVILEGE(
  privilege  IN  BINARY_INTEGER,
  revokee    IN  VARCHAR2);
```

Parameters

Table 75-16 REVOKE_SYSTEM_PRIVILEGE Procedure Parameters

Parameter	Description
privilege	The constant that specifies the privilege. See "Constants" for valid privileges.
revokee	The name of the user or role from which the privilege is revoked. The user who runs the procedure cannot be specified.

76
DBMS_FILE_TRANSFER

The DBMS_FILE_TRANSFER package provides procedures to copy a binary file within a database or to transfer a binary file between databases.

This chapter contains the following topics:

- Overview
- Security Model
- Operating Notes
- Summary of DBMS_FILE_TRANSFER Subprograms

> **See Also:**
>
> *Oracle Database Administrator's Guide* for instructions about using file transfer

76.1 DBMS_FILE_TRANSFER Overview

The DBMS_FILE_TRANSFER package provides procedures to copy a binary file within a database or to transfer a binary file between databases.

The destination database converts each block when it receives a file from a platform with different endianness. Datafiles can be imported after they are moved to the destination database as part of a transportable operation without RMAN conversion. Both GET and PUT operations will converted the file across platform difference at the destination. However, COPY is a local operation and therefore no conversion is required.

76.2 DBMS_FILE_TRANSFER Security Model

The DBMS_FILE_TRANSFER package must be created under SYS (CONNECT INTERNAL). Operations provided by this package are performed under the current calling user, not the package owner (SYS).

To use this interface the following users must have the following privileges:

- The current user at the local database must have READ privilege on the directory object specified in the source_directory_object parameter.
- The connected user at the destination database must have WRITE privilege to the directory object specified in the destination_directory_object parameter.

76.3 DBMS_FILE_TRANSFER Operational Notes

DBMS_FILE_TRANSFER supports online backup. You should therefore be careful in copying or transferring a file that is being modified by the database because this can result in an

inconsistent file, and require recovery. To guarantee consistency, bring files offline when the database is in use.

If you want to use DBMS_FILE_TRANSFER for performing backups, note that you are implementing self-managed backups, and should therefore put the files in hot backup mode.

76.4 Summary of DBMS_FILE_TRANSFER Subprograms

This table lists the DBMS_FILE_TRANSFER subprograms and briefly describes them.

Table 76-1 DBMS_FILE_TRANSFER Package Subprograms

Subprogram	Description
COPY_FILE Procedure	Reads a file from a source directory and creates a copy of it in a destination directory. The source and destination directories can both be in a local file system, or both be in an Automatic Storage Management (ASM) disk group, or between local file system and ASM with copying in either direction.
GET_FILE Procedure	Contacts a remote database to read a remote file and then creates a copy of the file in the local file system or ASM
PUT_FILE Procedure	Reads a local file or ASM and contacts a remote database to create a copy of the file in the remote file system

76.4.1 COPY_FILE Procedure

This procedure reads a file from a source directory and creates a copy of it in a destination directory. The source and destination directories can both be in a local file system, or both be in an Automatic Storage Management (ASM) disk group, or between local file system and ASM with copying in either direction.

You can copy any type of file to and from a local file system. However, you can copy only database files (such as datafiles, tempfiles, controlfiles, and so on) to and from an ASM disk group.

The destination file is not closed until the procedure completes successfully.

Syntax

```
DBMS_FILE_TRANSFER.COPY_FILE(
   source_directory_object       IN  VARCHAR2,
   source_file_name              IN  VARCHAR2,
   destination_directory_object  IN  VARCHAR2,
   destination_file_name         IN  VARCHAR2);
```

Parameters

Table 76-2 *COPY_FILE Procedure Parameters*

Parameter	Description
`source_directory_object`	The directory object that designates the source directory. The directory object must already exist. (You create directory objects with the `CREATE DIRECTORY` command).
`source_file_name`	The name of the file to copy. This file must exist in the source directory.
`destination_directory_object`	The directory object that designates the destination directory. The directory object must already exist. If the destination is ASM, the directory object must designate either a disk group name (for example, `+diskgroup1`) or a directory created for alias names. In the case of a directory, the full path to the directory must be specified (for example: `+diskgroup1/dbs/control`).
`destination_file_name`	The name to assign to the file in the destination directory. A file with the same name must not exist in the destination directory. If the destination is ASM: • The file is given a fully qualified ASM filename and created in the appropriate directory (depending on the database name and file type) • The file type tag assigned to the file is `COPY_FILE` • The value of the `destination_file_name` argument becomes the file's alias name in the designated destination directory The file name can be followed by an ASM template name in parentheses. The file is then given the attributes specified by the template.

Usage Notes

To run this procedure successfully, the current user must have the following privileges:

- `READ` privilege on the directory object specified in the `source_directory_object` parameter
- `WRITE` privilege on directory object specified in the `destination_directory_object` parameter

This procedure converts directory object parameters to uppercase unless they are surrounded by double quotation marks, but this procedure does not convert file names to uppercase.

Also, the copied file must meet the following requirements:

- The size of the copied file must be a multiple of 512 bytes.
- The size of the copied file must be less than or equal to two terabytes.

The `source_file_name` parameter must specify a file that is in the directory specified by the `source_directory_object` parameter before running the procedure, and the `destination_file_name` parameter must specify the new name of the file in the new location specified in the `destination_directory_object` parameter. Relative paths and symbolic

links are not allowed in the directory objects for the `source_directory_object` and `destination_directory_object` parameters.

Transferring the file is not transactional. To monitor the progress of a long file copy, query the `V$SESSION_LONGOPS` dynamic performance view.

> **See Also:**
>
> *Oracle Automatic Storage Management Administrator's Guide*for instructions about using file transfer

Examples

```
SQL> create directory DGROUP as '+diskgroup1/dbs/backup';

Directory created.

SQL>  BEGIN
   2    DBMS_FILE_TRANSFER.COPY_FILE('SOURCEDIR','t_xdbtmp.f', 'DGROUP',
                                     't_xdbtmp.f');
   3  END;
   4  /

PL/SQL procedure successfully completed.

SQL> EXIT
$ASMCMD
ASMCMD> ls
DISKGROUP1/
ASMCMD> cd diskgroup1/dbs/backup
ASMCMD> ls
t_xdbtmp.f => +DISKGROUP1/ORCL/TEMPFILE/COPY_FILE.267.546546525
```

76.4.2 GET_FILE Procedure

This procedure contacts a remote database to read a remote file and then creates a copy of the file in the local file system or ASM. The file that is copied is the source file, and the new file that results from the copy is the destination file. The destination file is not closed until the procedure completes successfully.

Syntax

```
DBMS_FILE_TRANSFER.GET_FILE
   source_directory_object      IN  VARCHAR2,
   source_file_name             IN  VARCHAR2,
   source_database              IN  VARCHAR2,
   destination_directory_object IN  VARCHAR2,
   destination_file_name        IN  VARCHAR2);
```

Parameters

Table 76-3 GET_FILE Procedure Parameters

Parameter	Description
source_directory_object	The directory object from which the file is copied at the source site. This directory object must exist at the source site.
source_file_name	The name of the file that is copied in the remote file system. This file must exist in the remote file system in the directory associated with the source directory object.
source_database	The name of a database link to the remote database where the file is located.
destination_directory_object	The directory object into which the file is placed at the destination site. This directory object must exist in the local file system.
destination_file_name	The name of the file copied to the local file system. A file with the same name must not exist in the destination directory in the local file system.

Usage Notes

To run this procedure successfully, the following users must have the following privileges:

- The connected user at the source database must have read privilege on the directory object specified in the source_directory_object parameter.
- The current user at the local database must have write privilege on the directory object specified in the destination_directory_object parameter.

This procedure converts directory object parameters to uppercase unless they are surrounded by double quotation marks, but this procedure does not convert file names to uppercase.

Also, the copied file must meet the following requirements:

- The size of the copied file must be a multiple of 512 bytes.
- The size of the copied file must be less than or equal to two terabytes.

Transferring the file is not transactional. To monitor the progress of a long file transfer, query the V$SESSION_LONGOPS dynamic performance view.

Examples

```
CREATE OR REPLACE DIRECTORY df AS '+datafile' ;
GRANT WRITE ON DIRECTORY df TO "user";
CREATE DIRECTORY DSK_FILES AS ''^t_work^'';
GRANT WRITE ON DIRECTORY dsk_files TO "user";

-- asumes that dbs2 link has been created and we are connected to the instance.
-- dbs2 could be a loopback or point to another instance.

BEGIN
-- asm file to an os file
-- get an asm file from dbs1.asm/a1 to dbs2.^t_work^/oa5.dat
  DBMS_FILE_TRANSFER.GET_FILE ( 'df' , 'a1' , 'dbs1', 'dsk_files' , 'oa5.dat' );
```

```
-- os file to an os file
-- get an os file from dbs1.^t_work^/a2.dat to dbs2.^t_work^/a2back.dat
  DBMS_FILE_TRANSFER.GET_FILE ( 'dsk_files' , 'a2.dat' , 'dbs1', 'dsk_files' ,
'a2back.dat' );

END ;
/
```

76.4.3 PUT_FILE Procedure

This procedure reads a local file or ASM and contacts a remote database to create a copy of the file in the remote file system.

The file that is copied is the source file, and the new file that results from the copy is the destination file. The destination file is not closed until the procedure completes successfully.

Syntax

```
DBMS_FILE_TRANSFER.PUT_FILE(
   source_directory_object       IN  VARCHAR2,
   source_file_name              IN  VARCHAR2,
   destination_directory_object  IN  VARCHAR2,
   destination_file_name         IN  VARCHAR2,
   destination_database          IN  VARCHAR2);
```

Parameters

Table 76-4 PUT_FILE Procedure Parameters

Parameter	Description
`source_directory_object`	The directory object from which the file is copied at the local source site. This directory object must exist at the source site.
`source_file_name`	The name of the file that is copied from the local file system. This file must exist in the local file system in the directory associated with the source directory object.
`destination_directory_object`	The directory object into which the file is placed at the destination site. This directory object must exist in the remote file system.
`destination_file_name`	The name of the file placed in the remote file system. A file with the same name must not exist in the destination directory in the remote file system.
`destination_database`	The name of a database link to the remote database to which the file is copied.

Usage Notes

To run this procedure successfully, the following users must have the following privileges:

- The current user at the local database must have read privilege on the directory object specified in the `source_directory_object` parameter.

- The connected user at the destination database must have write privilege to the directory object specified in the `destination_directory_object` parameter.

This procedure converts directory object parameters to uppercase unless they are surrounded by double quotation marks, but this procedure does not convert file names to uppercase.

Also, the copied file must meet the following requirements:

- The size of the copied file must be a multiple of 512 bytes.
- The size of the copied file must be less than or equal to two terabytes.

Transferring the file is not transactional. To monitor the progress of a long file transfer, query the `V$SESSION_LONGOPS` dynamic performance view.

Examples

```
CREATE OR REPLACE DIRECTORY df AS '+datafile' ;
GRANT WRITE ON DIRECTORY df TO "user";
CREATE OR REPLACE DIRECTORY ft1 AS '+datafile/ft1' ;
GRANT READ,WRITE ON DIRECTORY ft1 TO "user";
CREATE OR REPLACE DIRECTORY ft1_1 AS '+datafile/ft1/ft1_1' ;

CONNECT user;
Enter password: password

-- - put a1.dat to a4.dat (using dbs2 dblink)
-- - level 2 sub dir to parent dir
-- - user has read privs on ft1_1 at dbs1 and write on df in dbs2
BEGIN
 DBMS_FILE_TRANSFER.PUT_FILE ( 'ft1_1' , 'a2.dat' , 'df' , 'a4.dat' ,
                               'dbs2' ) ;
END ;
```

77
DBMS_FLASHBACK

Using DBMS_FLASHBACK, you can flash back to a version of the database at a specified time or a specified system change number (SCN).

This chapter contains the following topics:

- Overview
- Security Model
- Types
- Exceptions
- Operational Notes
- Examples
- Summary of DBMS_FLASHBACK Subprograms

> **See Also:**
>
> For detailed information about DBMS_FLASHBACK:
>
> - *Oracle Database Development Guide*
> - *Oracle Database SQL Language Reference*.

77.1 DBMS_FLASHBACK Overview

DBMS_FLASHBACK provides an interface for the user to view the database at a particular time in the past, with the additional capacity provided by transaction back out features that allow for selective removal of the effects of individual transactions. This is different from a flashback database which moves the database back in time.

When DBMS_FLASHBACK is enabled, the user session uses the Flashback version of the database, and applications can execute against the Flashback version of the database.

You may want to use DBMS_FLASHBACK for the following reasons:

- Self-service repair: If you accidentally delete rows from a table, you can recover the deleted rows.
- Packaged applications such as email and voicemail: You can use Flashback to restore deleted email by re-inserting the deleted message into the current message box.
- Decision support system (DSS) and online analytical processing (OLAP) applications: You can perform data analysis or data modeling to track seasonal demand.

77.2 DBMS_FLASHBACK Security Model

To use the DBMS_FLASHBACK package, you must have the EXECUTE privilege on it.

77.3 DBMS_FLASHBACK Types

The following table describes the types used by DBMS_FLASHBACK.

Table 77-1 DBMS_FLASHBACK

Type	Description
TXNAME_ARRAY	Creates a VARRAY for holding Transaction Names or Identifiers (XIDs)

77.4 DBMS_FLASHBACK Exceptions

DBMS_FLASHBACK creates the following error messages.

Table 77-2 DBMS_FLASHBACK Error Messages

Error	Description
ORA-08180	Time specified is too old
ORA-08181	Invalid system change number specified
ORA-08182	User cannot begin read-only or serializable transactions in Flashback mode
ORA-08183	User cannot enable Flashback within an uncommitted transaction
ORA-08184	User cannot enable Flashback within another Flashback session
ORA-08185	SYS cannot enable Flashback mode

77.5 DBMS_FLASHBACK Operational Notes

DBMS_FLASHBACK is automatically turned off when the session ends, either by disconnection or by starting another connection.

PL/SQL cursors opened in Flashback mode return rows as of the flashback time or SCN. Different concurrent sessions (connections) in the database can perform Flashback to different wall-clock times or SCNs. DML and DDL operations and distributed operations are not allowed while a session is running in Flashback mode. You can use PL/SQL cursors opened before disabling Flashback to perform DML.

Under Automatic Undo Management (AUM) mode, you can use retention control to control how far back in time to go for the version of the database you need. If you need to perform a Flashback over a 24-hour period, the DBA must set the undo_retention parameter to 24 hours. This way, the system retains enough undo information to regenerate the older versions of the data.

You can set the RETENTION GUARANTEE clause for the undo tablespace to ensure that unexpired undo is not discarded. UNDO_RETENTION is not in itself a guarantee because,

if the system is under space pressure, unexpired undo may be overwritten with freshly generated undo. In such cases, `RETENTION GUARANTEE` prevents this. For more information, see the *Oracle Database Administrator's Guide*.

In a Flashback-enabled session, `SYSDATE` is not affected; it continues to provide the current time.

`DBMS_FLASHBACK` can be used within logon triggers to enable Flashback without changing the application code.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for information on setting the minimum undo retention period.

77.6 DBMS_FLASHBACK Examples

The following example illustrates how Flashback can be used when the deletion of a senior employee triggers the deletion of all the personnel reporting to him. Using the Flashback feature, you can recover and re-insert the missing employees.

```
DROP TABLE employee;
DROP TABLE keep_scn;

REM -- Keep_scn is a temporary table to store scns that we are interested in

CREATE TABLE keep_scn (scn number);
SET ECHO ON
CREATE TABLE employee (
   employee_no   number(5) PRIMARY KEY,
   employee_name varchar2(20),
   employee_mgr  number(5)
      CONSTRAINT mgr_fkey REFERENCES EMPLOYEE ON DELETE CASCADE,
   salary        number,
   hiredate      date
);

REM -- Populate the company with employees
INSERT INTO employee VALUES (1, 'John Doe', null, 1000000, '5-jul-81');
INSERT INTO employee VALUES (10, 'Joe Johnson', 1, 500000, '12-aug-84');
INSERT INTO employee VALUES (20, 'Susie Tiger', 10, 250000, '13-dec-90');
INSERT INTO employee VALUES (100, 'Scott Tiger', 20, 200000, '3-feb-86');
INSERT INTO employee VALUES (200, 'Charles Smith', 100, 150000, '22-mar-88');
INSERT INTO employee VALUES (210, 'Jane Johnson', 100, 100000, '11-apr-87');
INSERT INTO employee VALUES (220, 'Nancy Doe', 100, 100000, '18-sep-93');
INSERT INTO employee VALUES (300, 'Gary Smith', 210, 75000, '4-nov-96');
INSERT INTO employee VALUES (310, 'Bob Smith', 210, 65000, '3-may-95');
COMMIT;

REM -- Show the entire org
SELECT lpad(' ', 2*(level-1)) || employee_name Name
FROM employee
CONNECT BY PRIOR employee_no = employee_mgr
START WITH employee_no = 1
ORDER BY LEVEL;
```

```
REM -- Sleep for a short time (approximately 10 to 20  seconds) to avoid
REM -- querying close to table creation

EXECUTE DBMS_LOCK.SLEEP(10);

REM -- Store this snapshot for later access through Flashback
DECLARE
I NUMBER;
BEGIN
I := DBMS_FLASHBACK.GET_SYSTEM_CHANGE_NUMBER;
INSERT INTO keep_scn VALUES (I);
COMMIT;
END;
/

REM -- Scott decides to retire but the transaction is done incorrectly
DELETE FROM EMPLOYEE WHERE employee_name = 'Scott Tiger';
COMMIT;

REM -- notice that all of scott's employees are gone
SELECT lpad(' ', 2*(level-1)) || employee_name Name
FROM EMPLOYEE
CONNECT BY PRIOR employee_no = employee_mgr
START WITH employee_no = 1
ORDER BY LEVEL;

REM -- Flashback to see Scott's organization
DECLARE
   restore_scn number;
BEGIN
   SELECT  scn INTO restore_scn FROM keep_scn;
   DBMS_FLASHBACK.ENABLE_AT_SYSTEM_CHANGE_NUMBER (restore_scn);
END;
/

REM -- Show Scott's org.
SELECT lpad(' ', 2*(level-1)) || employee_name Name
FROM employee
CONNECT BY PRIOR employee_no = employee_mgr
START WITH employee_no =
   (SELECT employee_no FROM employee WHERE employee_name = 'Scott Tiger')
ORDER BY LEVEL;

REM -- Restore scott's organization.
DECLARE
   scotts_emp NUMBER;
   scotts_mgr NUMBER;
   CURSOR c1 IS
      SELECT employee_no, employee_name, employee_mgr, salary, hiredate
      FROM employee
      CONNECT BY PRIOR employee_no = employee_mgr
      START WITH employee_no =
         (SELECT employee_no FROM employee WHERE employee_name = 'Scott Tiger');
   c1_rec c1 % ROWTYPE;
BEGIN
   SELECT employee_no, employee_mgr INTO scotts_emp, scotts_mgr FROM employee
   WHERE employee_name = 'Scott Tiger';
   /* Open c1 in flashback mode */
   OPEN c1;
   /* Disable Flashback */
   DBMS_FLASHBACK.DISABLE;
```

```
 LOOP
   FETCH c1 INTO c1_rec;
   EXIT WHEN c1%NOTFOUND;
   /*
     Note that all the DML operations inside the loop are performed
     with Flashback disabled
   */
   IF (c1_rec.employee_mgr = scotts_emp) then
      INSERT INTO employee VALUES (c1_rec.employee_no,
         c1_rec.employee_name,
         scotts_mgr,
         c1_rec.salary,
         c1_rec.hiredate);
   ELSE
   IF (c1_rec.employee_no != scotts_emp) THEN
   INSERT INTO employee VALUES (c1_rec.employee_no,
         c1_rec.employee_name,
         c1_rec.employee_mgr,
         c1_rec.salary,
         c1_rec.hiredate);
      END IF;
    END IF;
 END LOOP;
END;
/

REM -- Show the restored organization.
select lpad(' ', 2*(level-1)) || employee_name Name
FROM employee
CONNECT BY PRIOR employee_no = employee_mgr
START WITH employee_no = 1
ORDER BY LEVEL;
```

77.7 Summary of DBMS_FLASHBACK Subprograms

This table lists the `DBMS_FLASHBACK` subprograms and briefly describes them.

Table 77-3 DBMS_FLASHBACK Package Subprograms

Subprogram	Description
DISABLE Procedure	Disables the Flashback mode for the entire session
ENABLE_AT_SYSTEM_CHANGE_NUMBER Procedure	Enables Flashback for the entire session. Takes an SCN as an Oracle number and sets the session snapshot to the specified number. Inside the Flashback mode, all queries return data consistent as of the specified wall-clock time or SCN
ENABLE_AT_TIME Procedure	Enables Flashback for the entire session. The snapshot time is set to the SCN that most closely matches the time specified in `query_time`
GET_SYSTEM_CHANGE_NUMBER Function	Returns the current SCN as an Oracle number. You can use the SCN to store specific snapshots
TRANSACTION_BACKOUT Procedures	Provides the mechanism to back out a transaction

77.7.1 DISABLE Procedure

This procedure disables the Flashback mode for the entire session.

Syntax

```
DBMS_FLASHBACK.DISABLE;
```

Examples

The following example queries the salary of an employee, Joe, on August 30, 2000:

```
EXECUTE dbms_flashback.enable_at_time('30-AUG-2000');
SELECT salary FROM emp where name = 'Joe'
EXECUTE dbms_flashback.disable;
```

77.7.2 ENABLE_AT_SYSTEM_CHANGE_NUMBER Procedure

This procedure takes an SCN as an input parameter and sets the session snapshot to the specified number.

In the Flashback mode, all queries return data consistent as of the specified wall-clock time or SCN. It enables Flashback for the entire session.

Syntax

```
DBMS_FLASHBACK.ENABLE_AT_SYSTEM_CHANGE_NUMBER (
   query_scn IN NUMBER);
```

Parameters

Table 77-4 ENABLE_AT_SYSTEM_CHANGE_NUMBER Procedure Parameters

Parameter	Description
query_scn	The system change number (SCN), a version number for the database that is incremented on every transaction commit.

77.7.3 ENABLE_AT_TIME Procedure

This procedure enables Flashback for the entire session.

The snapshot time is set to the SCN that most closely matches the time specified in query_time. It enables Flashback for the entire session.

Syntax

```
DBMS_FLASHBACK.ENABLE_AT_TIME (
   query_time   IN TIMESTAMP);
```

Parameters

Table 77-5 ENABLE_AT_TIME Procedure Parameters

Parameter	Description

query_time	This is an input parameter of type TIMESTAMP. A time stamp can be specified in the following ways:
	• Using the TIMESTAMP constructor
	`EXECUTE DBMS_FLASHBACK.ENABLE_AT_TIME(TIMESTAMP '2001-01-09 12:31:00').`
	Use the Globalization Support (NLS) format and supply a string. The format depends on the Globalization Support settings.
	• Using the TO_TIMESTAMP function:
	`EXECUTE DBMS_FLASHBACK.ENABLE_AT_TIME(TO_TIMESTAMP('12-02-2001 14:35:00', 'DD-MM-YYYY HH24:MI:SS'))`
	You provide the format you want to use. This example shows the TO_TIMESTAMP function for February 12, 2001, 2:35 PM.
	• If the time is omitted from query time, it defaults to the beginning of the day, that is, 12:00 A.M.
	• Note that if the query time contains a time zone, the time zone information is truncated.

77.7.4 GET_SYSTEM_CHANGE_NUMBER Function

This function returns the current SCN as an Oracle number datatype. You can obtain the current change number and store it for later use. This helps you retain specific snapshots.

Syntax

```
DBMS_FLASHBACK.GET_SYSTEM_CHANGE_NUMBER
 RETURN NUMBER;
```

77.7.5 TRANSACTION_BACKOUT Procedures

This procedure provides a mechanism to back out a set of transactions. The user can call these procedures with either transaction names or transaction identifiers (XIDS).

The procedure analyzes the transactional dependencies, perform DMLs and generates an extensive report on the operation performed by the subprogram. This procedure does not commit the DMLs performed as part of transaction back out. However it holds all the required locks on rows and tables in the right form, so that no other dependencies can enter the system. To make the changes permanent you must explicitly commit the transaction.

A report is generated in the system tables DBA_FLASHBACK_TRANSACTION_STATE and DBA_FLASHBACK_TRANSACTION_REPORT.

Syntax

```
DBMS_FLASHBACK.TRANSACTION_BACKOUT
   numtxns            NUMBER,
   xids               XID_ARRAY,
```

```
   options            NUMBER default NOCASCADE,
   timeHint           TIMESTAMP default MINTIME);

DBMS_FLASHBACK.TRANSACTION_BACKOUT
   numtxns            NUMBER,
   xids               XID_ARRAY,
   options            NUMBER default NOCASCADE,
   scnHint            TIMESTAMP default 0   );

DBMS_FLASHBACK.TRANSACTION_BACKOUT
   numtxns           NUMBER,
   txnnames          TXNAME_ARRAY,
   options           NUMBER default NOCASCADE,
   timehint          TIMESTAMP MINTIME );

DBMS_FLASHBACK.TRANSACTION_BACKOUT
   numtxns           NUMBER,
   txnNames         TXNAME_ARRAY,
   options          NUMBER default NOCASCADE,
   scnHint          NUMBER 0);
```

Parameters

Table 77-6 TRANSACTION_BACKOUT Procedure Parameters

Parameter	Description
numtxns	Number of transactions passed as input
xids	List of transaction IDs in the form of an array
txnnames	List of transaction names in the form of an array
options	Back out dependent transactions: • NOCASCADE - No dependency is expected. If a dependency is found, this raises an error, with the first dependent transaction provided in the report. • NOCASCADE_FORCE - The user forcibly backs out the given transactions without considering the dependent transactions. The RDBMS executes the UNDO SQL for the given transactions in reverse order of their commit times. If no constraints break, and the result is satisfactory, the user can either COMMIT the changes or else ROLL BACK. • NONCONFLICT_ONLY - This option lets the user back out the changes to the nonconflicting rows of the given transactions. Note that a transaction dependency can happen due to a row conflict through either WAW or primary/unique key constraints. If the user chooses to back out only the nonconflicting rows, this does not cause any problem with database consistency, although transaction atomicity is lost. As this is a recovery operation, the user can correct the data. • CASCADE - This completely removes the given transactions including their dependents in a post order fashion (reverse order of commit times).
timehint	Time hint on the start of the transaction
scnhint	SCN hint on the start of the transaction

Usage Notes

> **Note:**
>
> For information about restrictions in using `TRANSACTION_BACKOUT`, see "Using Flashback Transaction" in the *Oracle Database Development Guide*.

- If transaction name is used, a time hint must be provided. The time hint should be a time before the start of all the given transactions to back out.
- If the SCN hint is provided, it must be before the start of the earliest transaction in the specified input set, or this raises an error and terminates. If it is not provided and the transaction has committed within undo retention, the database system is able to determine the start time.

78
DBMS_FLASHBACK_ARCHIVE

The `DBMS_FLASHBACK_ARCHIVE` package contains procedures for performing various flashback tasks.

These include:

- Disassociation and reassociation of a Flashback Archive enabled table from/with its underlying Flashback Data Archive (FDA)
- Tamper-proofing the tables of an application
- Importing of user history

> **Caution:**
>
> Importing user-generated history can lead to inaccurate, or unreliable results. This procedure should only be used after consulting with Oracle Support.

- Enabling and disabling of session-level support for valid-time

> **See Also:**
>
> *Oracle Database Development Guide* for more information about "Using Flashback Data Archive (Oracle Temporal)"

This chapter contains the following topics:

- Overview
- Security Model
- Constants
- Summary of DBMS_FLASHBACK_ARCHIVE Subprograms

78.1 DBMS_FLASHBACK_ARCHIVE Overview

Flashback Data Archive (FDA) provides strict protection on the internal history tables that it creates and maintains for users.

> **Caution:**
>
> The `DBMS_FLASHBACK_ARCHIVE` package does not support migration between databases. It allows you to move FDA history within the same database only, and not outside it. This package does not allow you to move FDA table data. It allows you to import customer history only and not FDA history.

The read-only semantics prohibit users, including a DBA, from doing updates, deletes, and inserts on the Flashback Data Archive internal history tables. Users are also prevented from issuing any DDL statements on these tables. This strict security enforcement helps meet the requirements of applications in regulatory / compliance environments. Flashback Data Archive supports most common DDL statements, including those that alter the table definition or incur data movement. However, some DDL statements are not supported on Flashback Archive enabled tables. Since most application schemas are modified during application software upgrades, the ability to perform DDL operations on tracked tables is critical.

To support schema evolution during application upgrades and other table maintenance tasks that require use of DDL statements not supported by Flashback Data Archive, the `DBMS_FLASHBACK_ARCHIVE` package provides a set of simple-to-use PL/SQL procedures:

- To disassociate a Flashback Archive enabled base table from the underlying FDA
- To reassociate a temporarily disassociated base table with its underlying FDA

After a user has disassociated the base table from its FDA, it's possible to issue any DDL statements on the base table or the history tables in the FDA. Having finished with the schema changes, the user can then reassociate the base table with its FDA so that Flashback Data Archive protection is in operation and automatic tracking and archiving is resumed.

78.2 DBMS_FLASHBACK_ARCHIVE Security Model

Users need the `FLASHBACK_ARCHIVE_ADMINISTER` privilege to import user-generated history, to set context level, and to tamper-proof tables. After a table is disassociated, users can perform DDL and DML statements on the table if they have the necessary privileges. Enabling and disabling session-level Valid Time Temporal flashback needs no additional privileges.

78.3 DBMS_FLASHBACK_ARCHIVE Constants

The `DBMS_FLASHBACK_ARCHIVE` package uses the constants shown in the following table.

Table 78-1 DBMS_FLASHBACK_ARCHIVE Constants

Constant	Type	Value	Description
NODROP	BINARY_INTEGER	1	Do not drop temporary history table
NOCOMMIT	BINARY_INTEGER	2	Do not commit transaction
NODELETE	BINARY_INTEGER	4	Do not delete data in history table

78.4 Summary of DBMS_FLASHBACK_ARCHIVE Subprograms

This table lists the DBMS_FLASHBACK_ARCHIVE subprograms and briefly describes them.

Table 78-2 DBMS_FLASHBACK_ARCHIVE Package Subprograms

Subprogram	Description
ADD_TABLE_TO_APPLICATION Procedure	Takes an application name and adds a table to the application as a security table
CREATE_TEMP_HISTORY_TABLE Procedure	Creates a table called TEMP_HISTORY with the correct definition in schema
DISABLE_APPLICATION Procedure	Takes an application name and marks a table in it as a security table
DISABLE_ASOF_VALID_TIME Procedure	Disables session level valid-time flashback
DISASSOCIATE_FBA Procedure	Disassociates the given table from the flashback data archive
DROP_APPLICATION Procedure	Takes an application name and removes it from the list of applications
ENABLE_APPLICATION Procedure	Takes an application name and enables Flashback Data Archive on all the security tables for this application
ENABLE_AT_VALID_TIME Procedure	Enables session level valid time flashback
EXTEND_MAPPINGS Procedure	Extends time mappings to times in the past
GET_SYS_CONTEXT Function	Gets the context previously selected by the SET_CONTEXT_LEVEL Procedure
IMPORT_HISTORY Procedure	Imports history from a table called TEMP_HISTORY in the given schema.
LOCK_DOWN_APPLICATION Procedure	Takes an application name and makes all the security tables read-only. The group called SYSTEM cannot be locked
PURGE_CONTEXT Procedure	Purges the context to be saved selected by the SET_CONTEXT_LEVEL Procedure
REASSOCIATE_FBA Procedure	Reassociates the given table with the flashback data archive
REGISTER_APPLICATION Procedure	Takes an application name and optionally a Flashback Data Archive, and registers an application for database hardening
REMOVE_TABLE_FROM_APPLICATION Procedure	Takes an application name and marks a table in it as no longer being a security table
SET_CONTEXT_LEVEL Procedure	Defines how much of the user context is to be saved

78.4.1 ADD_TABLE_TO_APPLICATION Procedure

This procedure takes an application name and adds a table to the application as a security table. If the application is enabled for Flashback Data Archive, then this table will also be enabled for Flashback Data Archive.

Syntax

```
DBMS_FLASHBACK_ARCHIVE.ADD_TABLE_TO_APPLICATION (
   application_name           IN   VARCHAR2,
   table_name                 IN   VARCHAR2,
   schema_name                IN   VARCHAR2 := NULL);
```

Parameters

Table 78-3 ADD_TABLE_TO_APPLICATION Procedure Parameters

Parameter	Description
application_name	Name of the application for which a table has been added as a security table
table_name	Name of the table to add as a security table for the given application
schema_name	Name of the schema containing the desired table. If no schema name is specified, the current schema is used.

78.4.2 CREATE_TEMP_HISTORY_TABLE Procedure

This procedure creates a table called TEMP_HISTORY with the correct definition in schema.

Syntax

```
DBMS_FLASHBACK_ARCHIVE.CREATE_TEMP_HISTORY_TABLE (
   owner_name1      IN   VARCHAR2,
   table_name1      IN   VARCHAR2);
```

Parameters

Table 78-4 CREATE_TEMP_HISTORY_TABLE Procedure Parameters

Parameter	Description
owner_name1	Schema of the Flashback Data Archive-enabled table
table_name1	Name of the Flashback Data Archive-enabled table

78.4.3 DISABLE_APPLICATION Procedure

This procedure takes an application name and disables Flashback Data Archive on all of its security tables.

Syntax

```
DBMS_FLASHBACK_ARCHIVE.DISABLE_APPLICATION (
   application_name           IN   VARCHAR2);
```

Parameters

Table 78-5 DISABLE_APPLICATION Procedure Parameters

Parameter	Description
application_name	Name of the application whose security tables will be disabled for Flashback Data Archive

78.4.4 DISABLE_ASOF_VALID_TIME Procedure

This procedure disables session level valid-time flashback.

Syntax

```
DBMS_FLASHBACK_ARCHIVE.DISABLE_ASOF_VALID_TIME;
```

78.4.5 DISASSOCIATE_FBA Procedure

This procedure disassociates the given table from the flashback data archive.

Syntax

```
DBMS_FLASHBACK_ARCHIVE.DISASSOCIATE_FBA (
   owner_name     IN    VARCHAR2,
   table_name     IN    VARCHAR2);
```

Parameters

Table 78-6 DISASSOCIATE_FBA Procedure Parameters

Parameter	Description
owner_name	Schema of the Flashback Data Archive enabled base table
table_name	Name of the Flashback Data Archive enabled base table

Exceptions

Table 78-7 DISASSOCIATE_FBA Procedure Exceptions

Exception	Description
ORA-55602	User table is not enabled for Flashback Data Archive

Table 78-7 (Cont.) DISASSOCIATE_FBA Procedure Exceptions

Exception	Description
ORA-55634	Cannot acquire the lock on the table for disassociation

78.4.6 DROP_APPLICATION Procedure

This procedure takes an application name and removes it from the list of applications. As part of this procedure, Flashback Data Archive will be disabled on all security-enabled tables and all history data will be lost. The group called SYSTEM cannot be dropped.

Syntax

```
DBMS_FLASHBACK_ARCHIVE.DROP_APPLICATION (
   application_name           IN   VARCHAR2);
```

Parameters

Table 78-8 DROP_APPLICATION Procedure Parameters

Parameter	Description
application_name	Name of the application for which a table has been added as a security table

78.4.7 ENABLE_APPLICATION Procedure

This procedure takes an application name and enables Flashback Data Archive on all the security tables for this application. Once an application is enabled, every change to an FDA enabled table will be tracked.

Syntax

```
DBMS_FLASHBACK_ARCHIVE.ENABLE_APPLICATION (
   application_name           IN   VARCHAR2);
```

Parameters

Table 78-9 ENABLE_APPLICATION Procedure Parameters

Parameter	Description
application_name	Name of the application for which to enable Flashback Data Archive on all its security tables

78.4.8 ENABLE_AT_VALID_TIME Procedure

This procedure enables session level valid time flashback.

Syntax

```
DBMS_FLASHBACK_ARCHIVE.ENABLE_AT_VALID_TIME (
   level          IN    VARCHAR2,
   query_time     IN    TIMESTAMP DEFAULT SYSTIMESTAMP);
```

Parameters

Table 78-10 ENABLE_AT_VALID_TIME Procedure Parameters

Parameter	Description
`level`	Options: • `All` - Sets the visibility of temporal data to the full table, which is the default temporal table visibility • `CURRENT` - Sets the visibility of temporal data to currently valid data within the valid time period at the session level • `ASOF` - Sets the visibility of temporal data to data valid as of the given time as defined by the timestamp
`query_time`	Used only if level is `ASOF`. Data which is valid at this `query_time` will only be shown.

78.4.9 EXTEND_MAPPINGS Procedure

This procedure extends time mappings to times in the past.

Syntax

```
DBMS_FLASHBACK_ARCHIVE.EXTEND_MAPPINGS;
```

78.4.10 GET_SYS_CONTEXT Function

This function gets the context previously selected by the SET_CONTEXT_LEVEL Procedure.

Syntax

```
DBMS_FLASHBACK_ARCHIVE.GET_SYS_CONTEXT (
   xid            IN   RAW,
   namespace      IN   VARCHAR2,
   parameter      IN   VARCHAR2)
 RETURN VARCHAR2;
```

Parameters

Table 78-11 GET_SYS_CONTEXT Function Parameters

Parameter	Description
`xid`	Transaction identifier is an opaque handle to a transaction obtained from the versions query

Table 78-11 (Cont.) GET_SYS_CONTEXT Function Parameters

Parameter	Description
namespace	Namespace
parameter	If undefined, the subprogram returns NULL

Related Topics

- SET_CONTEXT_LEVEL Procedure
  This procedure defines how much of the user context is to be saved.

78.4.11 IMPORT_HISTORY Procedure

This procedure is called after invoking the CREATE_TEMP_HISTORY_TABLE procedure, and after the TEMP_HISTORY table is populated with user-generated history data

> **Caution:**
>
> Importing user-generated history can lead to inaccurate, or unreliable results. This procedure should only be used after consulting with Oracle Support.
>
> The DBMS_FLASHBACK_ARCHIVE package does not support migration between databases. It allows you to move FDA history within the same database only, and not outside it. This package does not allow you to move FDA table data. It allows you to import customer history only and not FDA history.

Syntax

```
DBMS_FLASHBACK_ARCHIVE.IMPORT_HISTORY (
   owner_name1          IN   VARCHAR2,
   table_name1          IN   VARCHAR2
   temp_history_name    IN   VARCHAR2 DEFAULT 'TEMP_HISTORY',
   options              IN   BINARY_INTEGER DEFAULT 0);
```

Parameters

Table 78-12 IMPORT_HISTORY Procedure Parameters

Parameter	Description
owner_name1	Schema of the Flashback Data Archive-enabled table
table_name1	Name of the Flashback Data Archive-enabled table
temp_history_name	Optional temporary history table from which we import history data
options	One (or a combination) of constants (NODROP, NOCOMMIT, and NODELETE) to specify if we want to drop, commit changes of, or truncate the temporary history table

Usage Notes

The database function `TIMESTAMP_TO_SCN` can be used to convert times to SCN when populating the temporary history table.

Related Topics

- CREATE_TEMP_HISTORY_TABLE Procedure
  This procedure creates a table called `TEMP_HISTORY` with the correct definition in schema.

78.4.12 LOCK_DOWN_APPLICATION Procedure

This procedure takes an application name and makes all the security tables read-only. The group called `SYSTEM` cannot be locked.

Syntax

```
DBMS_FLASHBACK_ARCHIVE.LOCK_DOWN_APPLICATION (
   application_name           IN   VARCHAR2);
```

Parameters

Table 78-13 LOCK_DOWN_APPLICATION Procedure Parameters

Parameter	Description
`application_name`	Name of the application for which a table has been added as a security table

78.4.13 PURGE_CONTEXT Procedure

This procedure purges the context to be saved selected by the SET_CONTEXT_LEVEL Procedure.

Syntax

```
DBMS_FLASHBACK_ARCHIVE.PURGE_CONTEXT;
```

Related Topics

- SET_CONTEXT_LEVEL Procedure
  This procedure defines how much of the user context is to be saved.

78.4.14 REASSOCIATE_FBA Procedure

This procedure reassociates the given table with the flashback data archive.

Syntax

```
DBMS_FLASHBACK_ARCHIVE.REASSOCIATE_FBA (
   owner_name      VARCHAR2,
   table_name      VARCHAR2);
```

Parameters

Table 78-14 REASSOCIATE_FBA Procedure Parameters

Parameter	Description
owner_name	Schema of the Flashback Data Archive enabled base table
table_name	Name of the Flashback Data Archive enabled base table

Exceptions

Table 78-15 REASSOCIATE_FBA Procedure Exceptions

Parameter	Description
ORA-55602	User table is not enabled for Flashback Data Archive
ORA-55636	Table definition validation failed

Usage Notes

- The procedure will signal an error if the base table and the history table do not have identical data definitions. For example, when columns are added or table is split, the resulting base table and history table need to have the same schema.
- The FDA internal history table schema has some row versions metadata columns. The procedure will signal an error if any metadata column is dropped by users.

78.4.15 REGISTER_APPLICATION Procedure

This procedure takes an application name and optionally a Flashback Data Archive, and registers an application for database hardening.

When database hardening is enabled, then all the security tables for that application are enabled for Flashback Data Archive using the given Flashback Data Archive. If no Flashback Data Archive is specified, the default Flashback Data Archive is used.

> **See Also:**
>
> Using Flashback Data Archive in *Oracle Database Development Guide* regarding database hardening

Syntax

```
DBMS_FLASHBACK_ARCHIVE.REGISTER_APPLICATION (
   application_name           IN   VARCHAR2,
   flashback_archive_name     IN    VARCHAR2 := NULL);
```

Parameters

Table 78-16 REGISTER_APPLICATION Procedure Parameters

Parameter	Description
application_name	Name of the application which is being registered. The application SYSTEM is already registered when the package is created and is populated with list of tables needed for database hardening.
flashback_archive_name	Name of the Flashback Data Archive in which the historical data for the security tables for given application is stored. If no Flashback Data Archive is specified, the default Flashback Data Archive is used.

78.4.16 REMOVE_TABLE_FROM_APPLICATION Procedure

This procedure takes an application name and marks a table in it as no longer being a security table.

If the application is already enabled for Flashback Data Archive, Flashback Data Archive will be disabled for this table.

Syntax

```
DBMS_FLASHBACK_ARCHIVE.REMOVE_TABLE_TO_APPLICATION (
   application_name           IN   VARCHAR2,
   table_name                 IN   VARCHAR2,
   schema_name                IN   VARCHAR2 := NULL);
```

Parameters

Table 78-17 REMOVE_TABLE_FROM_APPLICATION Procedure Parameters

Parameter	Description
application_name	Name of the application for which a table is being removed from the list of security tables
table_name	Name of the table to mark as being no longer a security table for the given application
schema_name	Name of the schema containing the desired table. If no schema name is specified, the current schema is used.

78.4.17 SET_CONTEXT_LEVEL Procedure

This procedure defines how much of the user context is to be saved.

Syntax

```
DBMS_FLASHBACK_ARCHIVE.SET_CONTEXT_LEVEL (
   level          VARCHAR2);
```

Parameters

Table 78-18 SET_CONTEXT_LEVEL Procedure Parameters

Parameter	Description
`level`	Depending on how much of the user context needs to be saved: • `ALL` - the entire `SYS_CONTEXT` • `TYPICAL` - the user ID, global user ID and the hostname • `NONE` - nothing

79
DBMS_FLASHBACK_ARCHIVE_MIGRATE

Using the DBMS_FLASHBACK_ARCHIVE_MIGRATE package, you can export and import the Flashback Archive base tables along with their history to another database using the Transportable Tablespaces.

Restrictions

You can use this migration package only on a non-CDB environment.

This chapter contains the following topics:

- DBMS_FLASHBACK_ARCHIVE_MIGRATE Overview
- DBMS_FLASHBACK_ARCHIVE_MIGRATE Security Model
- DBMS_FLASHBACK_ARCHIVE_MIGRATE Operational Notes
- DBMS_FLASHBACK_ARCHIVE_MIGRATE Examples
- Summary of DBMS_FLASHBACK Subprograms

> **See Also:**
>
> For detailed information about DBMS_FLASHBACK_ARCHIVE_MIGRATE:
>
> - *Oracle Database Development Guide*
> - *Oracle Database SQL Language Reference*.

79.1 DBMS_FLASHBACK_ARCHIVE_MIGRATE Overview

Using this package one can export and import the Flashback Archive base tables along with their history to another database using the Transportable Tablespaces.

79.2 DBMS_FLASHBACK_ARCHIVE_MIGRATE Security Model

The DBMS_FLASHBACK_ARCHIVE_MIGRATE package must be compiled on both the source and target databases as SYS. The source file is located at ?/rdbms/admin/crefbamig.sql, using which the package can be created or compiled.

The export and import procedures must be executed as SYS. Since the package uses DBMS_DATAPUMP, DBMS_LOCK, DBMS_SYSTEM, DBMS_SQL. and DBMS_SCHEDULER PL/SQL packages, their Security Models are also applicable. Along with the user's FDA tables that are being exported the export function also exports the following SYS tables' data:

- SMON_SCN_TIME
- SYS_FBA_FA
- SYS_FBA_TSFA

- SYS_FBA_TRACKEDTABLES
- SYS_FBA_PARTITIONS
- SYS_FBA_USERS

79.3 DBMS_FLASHBACK_ARCHIVE_MIGRATE Operational Notes

This section describes how to use the `DBMS_FLASHBACK_ARCHIVE_MIGRATE` package.

Prerequisites

Database version >= 11.2

If database version is `11.2`, following conditions should be met:

- `shared_pool_size` >= 500M
- `streams_pool_size` >= 40M

or

- `sga_target` >= 2G

Constants

None

1. On the source database run `flashback_archive.export` to export the given Flashback Archive enabled tables, their history tables and other relevant metadata information using the transportable tablespaces.
2. Copy the transportable tablespace export dump and relevant datafiles from the source to the target database.
3. On the target database run `flashback_archive.import` to finish the import of the exported Flashback Archive enabled table and their history.

Extraneous objects

The tablespaces which host the Flashback Archive enabled tables and Flashback archive itself may have totally unrelated objects. During the export all those objects are also exported as the process uses the transportable tablespaces feature. Such extraneous objects are listed in the table `SYS_FBA_EXTRANEOUSOBJS`.

Upon successful import, the extraneous objects are left as is. DBA should drop the extraneous objects.

Self Containment of Tablespaces

Since transportable tablespaces feature is used for export and import, all the objects in those tablespaces must be self contained. Otherwise, the function aborts.

Reduction in History Granularity

After the import, it is possible to see the reduction in the granularity of the history.

For example, The multiple history generated on the source database in a small duaration of time may be coalesced into one history.

Logs

Export and import logs are available in the OS directory given as the input data_pump_dir argument.

The format of export logs is fda_mig_expdp_YYYY_MMDD_HH24MI.log

The format of import logs is fda_mig_impdp_YYYY_MMDD_HH24MI.log

Operational Notes

- After export, involved tablespaces are kept in READONLY mode so that the DBA can copy the involved datafiles.
- Keeping the involved tablespaces in READONLY mode also ensures the exported tables are in immutable state during exporting and copying of the datafiles.
- The procedures provided cannot be used for exporting and importing to change the table blocksizes. Because, internally these procedures use transportable tablespace export and import functionalities.
- After successful import, the tablespaces are again kept in READONLY mode. After the DBA verify the imported data, tablespaces can be made READ-WRITE.
- After successful import, the small tablespace that was given as input to the export operation can be dropped.

79.4 DBMS_FLASHBACK_ARCHIVE_MIGRATE Examples

This section illustrates exporting and importing Flashback Archive tables along with their history.

Step 1: Export the Flashback Archive enables tables along with their history

In the example, three Flashback Archive enabled tables USR1_TAB1, USR1_TAB2, and USR1_TAB3 are exported. These tables are spread across the FA1_TBSP, FA1_TBSP_1, USR1_TBSP, and USR1_TBSP_1 tablespaces.

The TTS_TBSP is a small tablespace that holds export related metadata.

/some/dir/with/enough/disk/space is the OS directory where data pump files and logs are created.

```
set serveroutput on;
declare
  l_fda_tabs dbms_sql.varchar2_table;
begin
  l_fda_tabs(1) := upper('usr1_tab1');
  l_fda_tabs(2) := upper('usr1_tab2');
  l_fda_tabs(3) := upper('usr1_tab3');
  flashback_archive_migrate.export
  ( schema_owner  => 'USR1'
  , fda_tables    => l_fda_tabs
  , tts           => 'TTS_TBSP'
  , data_pump_dir => '/some/dir/with/enough/disk/space'
  );
end;
/
```

On completion, the export output lists the datapump dump file and the datafiles that are to be copied to the target database to complete the import.

`Step 2`: Copy the datapump dump file and datafiles listed in the `Step 1` to the target database.

`Step 3`: Import the Flashback Archive tables along with their history

In the example, three Flashback Archive enabled tables `USR1_TAB1`, `USR1_TAB2`, and `USR1_TAB3` are imported from `FA1_TBSP`, `FA1_TBSP_1`, `USR1_TBSP`, and `USR1_TBSP_1` tablespaces spread over the data files.

For the example given, following are the data files captured in the export (`Step 1`) log file:

- `/u01/app/oracle/oradata/TGT_DB/tts_tbsp.dbf`
- `/u01/app/oracle/oradata/TGT_DB/usr1_tbsp.dbf`
- `/u01/app/oracle/oradata/TGT_DB/usr1_tbsp1.dbf`
- `/u01/app/oracle/oradata/TGT_DB/FA1_tbsp.dbf`
- `/u01/app/oracle/oradata/TGT_DB/FA1_tbsp_1.dbf`

The `TTS_TBSP` is a small tablespace that holds the export related metadata whose datafile is `/ade/nkedlaya_fda2/rdbms/dbs/tts_tbsp.dbf`.

`/some/dir/with/enough/disk/space` is the `OS` directory where data pump files are created.

```
set serveroutput on;
   declare
     l_data_files dbms_sql.varchar2_table;
   begin
     l_data_files(1) := '/u01/app/oracle/oradata/TGT_DB/tts_tbsp.dbf';
     l_data_files(2) := '/u01/app/oracle/oradata/TGT_DB/usr1_tbsp.dbf';
     l_data_files(3) := '/u01/app/oracle/oradata/TGT_DB/usr1_tbsp1.dbf';
     l_data_files(4) := '/u01/app/oracle/oradata/TGT_DB/FA1_tbsp.dbf';
     l_data_files(5) := '/u01/app/oracle/oradata/TGT_DB/FA1_tbsp_1.dbf';

     flashback_archive_migrate.import
     ( schema_owner   => 'USR1'
     , tts            => 'TTS_TBSP'
     , data_pump_dir  => '/data/pump/dir/where/export/dump/file/resides'
     , tts_data_files => l_data_files
     );
   end;
   /
```

Upon successful completion of the import, Flashback Archive is enabled on the imported tables and the prior history is available along with the new history that will be generated.

79.5 Summary of DBMS_FLASHBACK Subprograms

This table lists the `DBMS_FLASHBACK_ARCHIVE_MIGRATE` subprograms and briefly describes them.

Table 79-1 DBMS_FLASHBACK_ARCHIVE_MIGRATE Package Subprograms

Subprogram	Description
EXPORT Procedure	This procedure exports the given Flashback Archive enabled base tables, their history, and related tablespaces.
EXPORT_ANALYZE Procedure	This procedure analyzes the given Flashback Archive enabled base tables, their history, and related tablespaces for self containment using transportable tablesapce checks.
IMPORT Procedure	This procedure imports the Flashback Archive enabled base tables that were exported, their history, and related tablespaces.

79.5.1 EXPORT Procedure

This procedure exports the given Flashback Archive enabled base tables, their history, and related tablespaces.

Syntax

```
DBMS_FLASHBACK_ARCHIVE_MIGRATE.EXPORT (
   schema_owner         IN   VARCHAR2,
   fda_tables           IN   DBMS_SQL.VARCHAR2,
   tts                  IN   VARCHAR2,
   data_pump_dir        IN   VARCHAR2,
   ignore_errors        IN   BOOLEAN DEFAULT FALSE);
```

Parameters

Table 79-2 EXPORT Procedure Parameters

Parameter	Description
schema_owner	Flashback Archive enabled tables' owner
fda_tables	Array of Flashback Archive enabled tables
tts	A small tablespace that can be used to hold the export related metadata
data_pump_dir	The directory path in the operating system where the export dump is placed
ignore_errors	Ignore any transportable tablespaces errors. The default value is FALSE.

79.5.2 EXPORT_ANALYZE Procedure

This procedure analyzes the given Flashback Archive enabled base tables, their history, and related tablespaces for self containment using Transportable tablesapce checks.

Syntax

```
DBMS_FLASHBACK_ARCHIVE_MIGRATE.EXPORT_ANALYZE (
   schema_owner         IN   VARCHAR2,
   fda_tables           IN   DBMS_SQL.VARCHAR2,
   tts                  IN   VARCHAR2);
```

Parameters

Table 79-3 EXPORT_ANALYZE Procedure Parameters

Parameter	Description
schema_owner	Flashback Archive enabled tables' owner
fda_tables	Array of Flashback Archive enabled tables
tts	A small tablespace that can be used to hold the export related metadata

79.5.3 IMPORT Procedure

This procedure Imports the Flashback Archive enabled base tables that were exported, their history, and related tablespaces.

Syntax

```
DBMS_FLASHBACK_ARCHIVE_MIGRATE.IMPORT (
   schema_owner         IN   VARCHAR2,
   tts                  IN   VARCHAR2,
   data_pump_dir        IN   VARCHAR2,
   tts_data_files       IN   DBMS_SQL.VARCHAR2_TABLE);
```

Parameters

Table 79-4 IMPORT Procedure Parameters

Parameter	Description
schema_owner	Flashback Archive enabled tables' owner
tts	A small tablespace that can be used to hold the export related metadata
data_pump_dir	The directory path in the operating system where the export dump is placed
tts_data_files	The data files list of TTS exported tablespaces.

80
DBMS_FREQUENT_ITEMSET

The DBMS_FREQUENT_ITEMSET package enables frequent itemset counting. The two functions are identical except in the input cursor format difference.

This chapter contains the following topics:

- Summary of DBMS_FREQUENT_ITEMSET Subprograms

80.1 Summary of DBMS_FREQUENT_ITEMSET Subprograms

The `DBMS_FREQUENT_ITEMSET` package includes the `FI_HORIZONTAL` function and `FI_TRANSACTIONAL` function subprograms.

Table 80-1 DBMS_FREQUENT_ITEMSET Package Subprograms

Subprogram	Description
FI_HORIZONTAL Function	Counts all frequent itemsets given a cursor for input data which is in 'HORIZONTAL' row format, support threshold, minimum itemset length, maximum itemset length, items to be included, items to be excluded
FI_TRANSACTIONAL Function	Counts all frequent itemsets given a cursor for input data which is in 'TRANSACTIONAL' row format, support threshold, minimum itemset length, maximum itemset length, items to be included, items to be excluded

80.1.1 FI_HORIZONTAL Function

The purpose of this table function is to count all frequent itemsets given a cursor for input data which is in 'HORIZONTAL' row format, support threshold, minimum itemset length, maximum itemset length, items to be included, items to be excluded. The result will be a table of rows in form of itemset, support, length, total transactions counted.

In 'HORIZONTAL' row format, each row contains all of the item ids for a single transaction. Since all of the items come together, no transaction id is necessary.

The benefit of this table function is that if an application already has data in horizontal format, the database can skip the step of transforming rows that are in transactional format into horizontal format.

Syntax

```
DBMS_FREQUENT_ITEMSET.FI_HORIZONTAL(
   tranx_cursor         IN    SYSREFCURSOR,
   support_threshold    IN    NUMBER,
   itemset_length_min   IN    NUMBER,
   itemset_length_max   IN    NUMBER,
   including_items      IN    SYS_REFCURSOR DEFAULT NULL,
   excluding_items      IN    SYS_REFCURSOR DEFAULT NULL)
```

```
RETURN TABLE OF ROW (
   itemset [Nested Table of Item Type DERIVED FROM tranx_cursor],
   support        NUMBER,
   length         NUMBER,
   total_tranx    NUMBER);
```

Parameters

Table 80-2 FI_HORIZONTAL Function Parameters

Parameter	Description
tranx_cursor	The cursor parameter that the user will supply when calling the function. There is no limits on the number of returning columns.Each column of cursor represents an item. All columns of the cursor must be of the same datatype. The item id must be number or character type (for example, VARCHAR2(n)).
support_threshold	A fraction number of total transaction count. An itemset is termed "frequent" if [the number of transactions it occurs in] divided by [the total number of transactions] exceed the fraction. The parameter must be a NUMBER.
itemset_length_min	The minimum length for interested frequent itemset. The parameter must be a NUMBER between 1 and 20, inclusive.
itemset_length_max	The maximum length for interested frequent itemset. This parameter must be a NUMBER between 1 and 20, inclusive, and must not be less than itemset_length_min.
including_items	A cursor from which a list of items can be fetched. At least one item from the list must appear in frequent itemsets that are returned. The default is NULL.
excluding_items	A cursor from which a list of items can be fetched. No item from the list can appear in frequent itemsets that are returned.The default is NULL.

Return Values

Table 80-3 FI_HORIZONTAL Return Values

Parameter	Description
support	The number of transactions in which a frequent itemset occurs. This will be returned as a NUMBER.
itemset	A collection of items which is computed as frequent itemset. This will be returned as a nested table of item type which is the item column type of the input cursor.
length	Number of items in a frequent itemset. This will be returned as a NUMBER.
total_tranx	The total transaction count. This will be returned as a NUMBER.

Example

Suppose you have a table horiz_table_in.

```
horiz_table_in(iid1 VARCHAR2(30), iid2 VARCHAR2(30), iid3 VARCHAR2(30), iid4
VARCHAR2(30), iid5 VARCHAR2(30));
```

and the data in horiz_table_in looks as follows:

```
('apple', 'banana', NULL, NULL, NULL)
('apple', 'milk', 'banana', NULL, NULL)
('orange', NULL, NULL, NULL, NULL)
```

Suppose you want to find out what combinations of items is frequent with a given support threshold of 30%, requiring itemset containing at least one of ('apple','banana','orange'), but excluding any of ('milk') in any itemset. You use the following query:

```
CREATE TYPE fi_varchar_nt AS TABLE OF VARCHAR2(30);
SELECT CAST(itemset as FI_VARCHAR_NT)itemset, support, length, total_tranx
   FROM table(DBMS_FREQUENT_ITEMSET.FI_HORIZONTAL(
                CURSOR(SELECT iid1, iid2, iid3, iid4, iid5
                         FROM horiz_table_in),
                0.3,
                2,
                5,
                CURSOR(SELECT * FROM table(FI_VARCHAR_NT
                                           ('apple','banana','orange'))),
                CURSOR(SELECT * FROM table(FI_VARCHAR_NT('milk'))))));
```

80.1.2 FI_TRANSACTIONAL Function

This procedure counts all frequent itemsets given a cursor for input data which is in 'TRANSACTIONAL' row format, support threshold, minimum itemset length, maximum itemset length, items to be included, items to be excluded. The result will be a table of rows in form of itemset, support, length, total number of transactions.

In 'TRANSACTIONAL' row format, each transaction is spread across multiple rows. All the rows of a given transaction have the same transaction id, and each row has a different item id. Combining all of the item ids which share a given transaction id results in a single transaction.

Syntax

```
DBMS_FREQUENT_ITEMSET.FI_TRANSACTIONAL (
   tranx_cursor         IN    SYSREFCURSOR,
   support_threshold    IN    NUMBER,
   itemset_length_min   IN    NUMBER,
   itemset_length_max   IN    NUMBER,
   including_items      IN    SYS_REFCURSOR DEFAULT NULL,
   excluding_items      IN    SYS_REFCURSOR DEFAULT NULL)
  RETURN TABLE OF ROW (
     itemset [Nested Table of Item Type DERIVED FROM tranx_cursor],
     support        NUMBER,
     length         NUMBER,
     total_tranx    NUMBER);
```

Parameters

Table 80-4 *FI_TRANSACTIONAL Function Parameters*

Parameter	Description
`tranx_cursor`	The cursor parameter that the user will supply when calling the function. It should return two columns in its returning row, the first column being the transaction id, the second column being the item id. The item id must be number or character type (for example, `VARCHAR2(n)`).
`support_threshold`	A fraction number of total transaction count. An itemset is termed "frequent" if [the number of transactions it occurs in] divided by [the total number of transactions] exceed the fraction. The parameter must be a `NUMBER`.
`itemset_length_min`	The minimum length for interested frequent itemset. The parameter must be a `NUMBER` between 1 and 20, inclusive.
`itemset_length_max`	The maximum length for interested frequent itemset. This parameter must be a `NUMBER` between 1 and 20, inclusive, and must not be less than `itemset_length_min`.
`including_items`	A cursor from which a list of items can be fetched. At least one item from the list must appear in frequent itemsets that will be returned. The default is `NULL`.
`excluding_items`	A cursor from which a list of items can be fetched. No item from the list can appear in frequent itemsets that will returned. The default is `NULL`.

Return Values

Table 80-5 FI_TRANSACTIONAL Return Values

Parameter	Description
`support`	The number of transactions in which a frequent itemset occurs. This will be returned as a `NUMBER`.
`itemset`	A collection of items which is computed as frequent itemset. This will be returned as a nested table of item type which is the item column type of the input cursor.
`length`	Number of items in a frequent itemset. This will be returned as a `NUMBER`.
`total_tranx`	The total transaction count. This will be returned as a `NUMBER`, and will be the same for all returned rows, similar to a reporting aggregate.

Usage Notes

Applications must predefine a nested table type of the input item type and cast the output itemset into this predefined nested table type before further processing, such as loading into a table.

Examples

Suppose that the input table `tranx_table_in` looks as follows:

```
(1, 'apple')
(1, 'banana')
(2, 'apple')
(2, 'milk')
(2, 'banana')
(3, 'orange')
```

and the user is trying to find itemsets that satisfy a support-threshold of 60% and have the itemset-length greater than 1 (namely, (apple, banana)).

The output of this function would contain the following output row:

```
itemset=('apple','banana'), support=2, length=2, total_tranx=3
```

You need to create a nested table of item type before you submit a query to perform the frequent itemset counting. In this example, since item is of `VARCHAR2(30)`, you must create a nested table of `VARCHAR2(30)`:

```
CREATE TYPE fi_varchar_nt AS TABLE OF VARCHAR2(30);
SELECT CAST(itemset as FI_VARCHAR_NT) itemset, support, length, total_tranx
   FROM table(DBMS_FREQUENT_ITEMSET.FI_TRANSACTIONAL(
                cursor(SELECT tid, iid FROM tranx_table_in),
                0.6,
                2,
                5,
                NULL,
                NULL));
```

Here is another example to illustrate how to include certain items and exclude certain items in the counting.

```
SELECT CAST(itemset as FI_VARCHAR_NT)itemset, support, length, total_tranx
   FROM table(DBMS_FREQUENT_ITEMSET.FI_TRANSACTIONAL(
                CURSOR(SELECT tid, iid FROM tranx_table_in),
                0.6,
                2,
                5,
               CURSOR(SELECT * FROM table(FI_VARCHAR_NT
                                ('apple','banana','orange'))),
               CURSOR(SELECT * FROM table(FI_VARCHAR_NT('milk')))));
```

Using the including/excluding items parameter, you are able to further optimize the execution by ignoring itemsets that are not expected by application.

You can also use transactional output through collection unnesting:

```
  SELECT
    bt.setid, nt.*
  FROM
  (SELECT cast(Itemset as FI_VARCHAR_NT) itemset, rownum setid
   FROM table(
     DBMS_FREQUENT_ITEMSET.FI_TRANSACTIONAL(
       CURSOR(SELECT tid, iid FROM tranx_table_in), 0.6, 2, 5,
       NULL, NULL))) bt,
  table(bt.itemset) nt;
```

If you want to use an insert statement to load frequent itemsets into a nested table, it is better to use the `NESTED_TABLE_FAST_INSERT` hint for performance:

```
  CREATE TABLE fq_nt (coll FI_VARCHAR_NT) NESTED TABLE coll STORE AS
    coll_nest;
  INSERT /*+ NESTED_TABLE_FAST_INSERT */  INTO fq_nt
   SELECT cast(itemset as FI_VARCHAR_NT)
   FROM table(DBMS_FREQUENT_ITEMSET.FI_TRANSACTIONAL(
          cursor(SELECT tid, iid FROM tranx_table_in), 0.6, 2, 5,
          NULL, NULL));
```

Note that if you want to use the package inside a PL/SQL cursor, you must cast the return type of the table function:

```
  CREATE TYPE fi_res AS OBJECT (
    itemset      FI_VARCHAR_NT,
    support      NUMBER,
    length       NUMBER,
    total_tranx  NUMBER
  );
  /
  CREATE TYPE fi_coll AS TABLE OF fi_res;
  /

  DECLARE
    cursor freqC is
      SELECT Itemset
      FROM table(
        CAST(DBMS_FREQUENT_ITEMSET.FI_TRANSACTIONAL(
          cursor(SELECT tid, iid FROM tranx_table_in), 0.6, 2, 5,
          NULL, NULL) AS fi_coll));
    coll_nt  FI_VARCHAR_NT;
    num_rows int;
    num_itms int;
  BEGIN
    num_rows := 0;
    num_itms := 0;
    OPEN freqC;
    LOOP
      FETCH freqC INTO coll_nt;
      EXIT WHEN freqC%NOTFOUND;
      num_rows := num_rows + 1;
      num_itms := num_itms + coll_nt.count;
    END LOOP;
  CLOSE freqC;
  DBMS_OUTPUT.PUT_LINE('Totally ' || num_rows || ' rows ' || num_itms || '
items were produced.');
END;
/
```

81
DBMS_FS

The DBMS_FS package for performing operations on an Oracle file system (make, mount, unmount and destroy operations) in an Oracle database.

This chapter contains the following topics:

- DBMS_FS Overview
- DBMS_FS Security Model
- Summary of DBMS_FS Subprograms

81.1 DBMS_FS Overview

The DBMS_FS package contains Oracle file system (OFS) procedures that you can use to create, mount, unmount, and destroy an Oracle file system.

Starting 19c release, the file systems are supported by PDB. Oracle Database supports maximum 5 file systems per PDB and 1000 file systems in total.

The DBMS_FS package enables applications to access database objects from a universal client such as an NFS server. This feature interfaces with Oracle SecureFiles to provide the file system access.

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for a detailed description of managing an NFS server in Oracle Database

81.2 DBMS_FS Security Model

You must have the SYSDBA administrative privilege to use the DBMS_FS package.

The operations that you perform using the DBMS_FS package are equivalent to the file system operations that are performed in an operating system by the root user. Access to the individual file system that is created and mounted by this package is enforced using Access Control Lists (ACLs) and the permissions on the mounted directories to the operating system user.

81.3 Summary of DBMS_FS Subprograms

This table lists the DBMS_FS subprograms and briefly describes them.

Table 81-1 DBMS_FS Subprograms

Subprogram	Description
DESTROY_ORACLE_FS Procedure	Destroys an Oracle file system, using the `fstype` and of name `fsname`
MAKE_ORACLE_FS Procedure	Creates a file system of type specified by `fstype` and of name `fsname`
MOUNT_ORACLE_FS Procedure	Mounts an Oracle file system on the specified mount point
UNMOUNT_ORACLE_FS Procedure	Unmounts an Oracle file system on the specified mount point

81.3.1 DESTROY_ORACLE_FS Procedure

This procedure destroys an Oracle file system and then frees the resources that were associated with it.

Syntax

```
DBMS_FS.DESTROY_ORACLE_FS (
   fstype      IN VARCHAR2,
   fsname      IN VARCHAR2);
```

Parameters

Table 81-2 DBMS_FS Parameters

Parameter	Description
`fstype`	File system type. Oracle File System (OFS) and Database File System (DBFS) are supported.
`fsname`	Name of the file system

Usage Notes

- You can find information about the currently mounted file systems by querying the `V$OFSMOUNT` dynamic view.
- For more information about the file system types, see the `fstype` description in MAKE_ORACLE_FS Procedure.
- Before you run the `DBMS_FS.DESTROY_ORACLE_FS` procedure, you must unmount the file system by using the `DBMS_FS.UNMOUNT_ORACLE_FS` procedure.
- After you run `DBMS_FS.DESTROY_ORACLE_FS`, Oracle Database destroys the file system and frees the associated resources.

Example

This example shows how to destroy an DBFS file system:

```
BEGIN
 DBMS_FS.DESTROY_ORACLE_FS (
  fstype           => 'dbfs',
```

```
  fsname          => 'dbfs_fs1');
END;
/
```

81.3.2 MAKE_ORACLE_FS Procedure

This procedure creates a new file system of type DBFS, on top of an existing Oracle tablespace or other database object.

Syntax

```
DBMS_FS.MAKE_ORACLE_FS (
   fstype      IN VARCHAR2,
   fsname      IN VARCHAR2,
   fsoptions   IN VARCHAR2);
```

Parameters

Table 81-3 DBMS_FS Parameters

Parameter	Description
fstype	File system type. Enter one of the following values: • ofs—to create an Oracle File System • dbfs—to create a Database File System
fsname	Name of the file system. Enter a string no longer than 256 characters, using alphanumeric characters.
fsoptions	Specify an existing tablespace to use for the Oracle file system, using the following format: "tablespace=*tablespace_name*"

Usage Notes

- If you want to create a database file system (DBFS), then you must run the dbfs_create_filesystem.sql script, which in turn calls the dbfs_create_filesystem_advanced.sql script. By default, this script is in the $ORACLE_HOME/rdbms/admin directory. When you run this script, provide the name of an existing tablespace and a name for the file system that will be stored in the database. The size of the file system will be the same as the table size. For example, to create a file system in the dbfs_ts tablespace, in the file system dbfs_tab:

  ```
  @/$ORACLE_HOME/rdbms/admin/dbfs_create_filesystem.sql dbfs_ts dbfs_tab
  ```

  After you run this script, you can use the other procedures in the DBMS_FS package to mount, unmount, and destroy the file system.

> **Note:**
>
> Staring Oracle Database 19.3.1.0 release, the DBMS_FS.MAKE_ORACLE_FS is used to create a DBFS filesystem; hence no auxiliary SQL script is needed to create a DBFS filesystem.

- Running the DBMS_FS.MAKE_ORACLE_FS procedure on the database instance is equivalent to running the mkfs command by root in an operating system.
- The tablespace that you specified in the fsoptions parameter must already exist before you execute the DBMS_FS.MAKE_ORACLE_FS procedure. To find existing tablespaces, query the DBA_TABLESPACES data dictionary view.
- The size of the file system is the same size as this tablespace.

Example

This example shows how to create an DBFS file system:

```
BEGIN
 DBMS_FS.MAKE_ORACLE_FS (
  fstype           => 'dbfs',
  fsname           => 'dbfs_fs1',
  mount_options    => 'TABLESPACE=dbfs_fs1_tbspc');
END;
/
```

81.3.3 MOUNT_ORACLE_FS Procedure

This procedure mounts an Oracle file system on the specified mount point.

Syntax

```
DBMS_FS.MOUNT_ORACLE_FS (
  fstype           IN VARCHAR2,
  fsname           IN VARCHAR2,
  mount_point      IN VARCHAR2,
  mount_options    IN VARCHAR2);
```

Parameters

Table 81-4 MOUNT_ORACLE_FS Procedure Parameters

Parameter	Description
fstype	File system type. Oracle File System (OFS) and Database File System (DBFS) are supported.
fsname	Name of the file system. Enter a string no longer than 256 characters, using alpha numeric characters.
mount_point	Local directory where the file system should be mounted. This directory must already exist. Enter an absolute path. The maximum number of mount points that you can create is 5 mount points per PDB and 1000 mount points per instance.
mount_options	Comma-separated mount options, listed in Table 81-5.

Usage Notes

Table 81-5 Supported Mount Options for the MOUNT_ORACLE_FS procedure

Mount Option	Usage Description
`default_permissions`	Enables permission check and restrict access based on file mode. This option is useful with the `allow_other` mount option.
`allow_other`	Allows other users apart from the operating system user that did the mount can access the files. This will be used in conjunction with permission checks in determining the file access. This option requires setting the `user_allow_other` parameter in the `/etc/fuse.conf` configuration file on Linux.
`max_read`	Maximum size of the read operation. No maximum size is set by default.
`max_write`	Maximum write size in a single request. The default is 128K.
`direct_io`	Indicates to the operating system kernel not use file system cache.
`nopersist`	Does not store the mount options for use in next instance startup.
`persist`	Stores the mount entry persistently so that on subsequent instance startup it will be automatically mounted again. This option is supported for both `ofs` and `dbfs`.
`ro`	Mounts the file system in read-only mode. Files cannot be modified.
`rw`	Mounts the file system as read-write. This is the default.
`nosuid`	Specifies that the file system cannot contain set userid files.
`suid`	Specifies that the file system can contain set userid files. This is the default.

Note:

The following options are exclusive options and cannot be used together:

- `nopersist/persist`
- `ro/rw`
- `nosuid/suid`

Usage Notes

- This procedure makes the files system visible in the local database instance.
- For more information about the file system types, see the `fstype` description in MAKE_ORACLE_FS Procedure.

- You can find information about currently mounted file systems by querying the V$OFSMOUNT dynamic view.
- Run the DBMS_FS.MOUNT_ORACLE_FS procedure on a file system that has already been created with DBMS_FS.MAKE_ORACLE_FS in the local computer node where the Oracle database instance is running. You cannot run this procedure on file systems that were created outside of Oracle Database.

Example

```
BEGIN
 DBMS_FS.MOUNT_ORACLE_FS (
  fstype           => 'dbfs',
  fsname           => 'dbfs_fs1',
  mount_point      => '/oracle/dbfs/testfs',
  mount_options    => 'default_permissions, allow_other, persist');
END;
```

81.3.4 UNMOUNT_ORACLE_FS Procedure

This procedure unmounts an Oracle file system on the specified mount point.

Syntax

```
DBMS_FS.UNMOUNT_ORACLE_FS (
  fsname             IN VARCHAR2,
  mount_point        IN VARCHAR2,
  unmount_options    IN VARCHAR2);
```

Table 81-6 UNMOUNT_ORACLE_FS Procedure Parameters

Parameter	Description
fsname	Name of the file system
mount_point	Local directory where the file system had been mounted. Enter an absolute path.
unmount_options	Optionally, enter force to unmount the file system forcibly. This setting prevents new requests from being sent to the file system. All pending requests on the file system are either completed or cancelled. If you omit this setting, then attempts to unmount a busy file system cause an EBUSY error.

Usage Notes

- Before you unmount the file system, ensure that all applications that use this file system are shut down. Also ensure that no processes refernce the mounting file system.
- You can find information about the currently mounted file systems by querying the V$OFSMOUNT dynamic view.
- For more information about the file system types, see the fstype description in MAKE_ORACLE_FS Procedure.

- When an Oracle instance is shut down in normal immediate mode, then all the mounted file systems are automatically unmounted.
- If a file system is mounted with the `MOUNT_ORACLE_FS` procedure with the `persist` option, it will be automatically mounted again when the database instance starts or the PDB is plugged. If this file system is unmounted by executing `DBMS_FS.UNMOUNT_ORACLE_FS`, it will remain unmounted even if the `persist` option was used to mount it.
- If you perform a `SHUTDOWN ABORT`, then the file system may still show as mounted but not accessible. In this case, you must unmount the system manually by calling `unmount` command at the operating system level or `fusermount` procedure on Linux systems.
- You can export the local mount point of an Oracle file system to point to the remote system, and then NFS mount the file system from the remote system by using the operating system `mount` command. The `DBMS_FS.MOUNT_ORACLE_FS` procedure is similar to `mount` commands that are used for other local file systems.
- For better security, Oracle recommends that you use access control lists (ACLs) and Kerberos to control access to sensitive data.
- Do not attempt to unmount the file system from the operating system level. Doing so can leave the Oracle Database-created file system internal tables in an inconsistent state.

Example

```
BEGIN
 DBMS_FS.UNMOUNT_ORACLE_FS (
  fsname           => 'dbfs_fs1',
  mount_point      => '/oracle/dbfs/testfs',
  mount_options    => 'force');
END;
```

82
DBMS_GOLDENGATE_ADM

The DBMS_GOLDENGATE_ADM package provides subprograms to configure and manage Oracle GoldenGate conflict detection and resolution.

This chapter contains the following topics:

- Using DBMS_GOLDENGATE_ADM
- Summary of DBMS_GOLDENGATE_ADM Subprograms

82.1 Using DBMS_GOLDENGATE_ADM

This section contains topics which relate to using the DBMS_GOLDENGATE_ADM package.

- DBMS_GOLDENGATE_ADM Overview
- DBMS_GOLDENGATE_ADM Security Model

82.1.1 DBMS_GOLDENGATE_ADM Overview

The DBMS_GOLDENGATE_ADM package provides interfaces to configure automatic conflict detection and resolution in an Oracle GoldenGate configuration that replicates tables between Oracle databases.

When more than one replica of a table allows changes to the table, a conflict can occur when a change is made to the same row in two different databases at nearly the same time. Oracle GoldenGate replicates changes using row logical change records (LCRs). It detects a conflict by comparing the old values in the row LCR with the current values of the corresponding table row identified by the key columns. If any column value does not match, then there is a conflict. After a conflict is detected, Oracle GoldenGate can resolve the conflict by overwriting values in the row with some values from the row LCR, ignoring the values in the row LCR, or computing a delta to update the row values.

XStream inbound servers and outbound servers can be used in an XStream configuration in a multitenant container database (CDB). A CDB is an Oracle database that includes zero, one, or many user-created pluggable databases (PDBs).

> **Note:**
>
> Using XStream requires purchasing a license for the Oracle GoldenGate product.

> **See Also:**
>
> - *Oracle Database XStream Guide*
> - *Oracle Database Concepts* for more information about CDBs and PDBs

82.1.2 DBMS_GOLDENGATE_ADM Security Model

Security on this package can be controlled either by granting `EXECUTE` on this package to selected users or roles or by granting `EXECUTE_CATALOG_ROLE` to selected users or roles.

If subprograms in the package are run from within a stored procedure, then the user who runs the subprograms must be granted `EXECUTE` privilege on the package directly. It cannot be granted through a role.

An Oracle GoldenGate administrator must be configured at each Oracle database in the table's replication environment, and Oracle GoldenGate must be configured to replicate the table at each Oracle database. You can configure an Oracle GoldenGate administrator using the `GRANT_ADMIN_PRIVILEGE` procedure in the `DBMS_GOLDENGATE_ADM` package.

> **See Also:**
>
> The Oracle GoldenGate documentation for more information about Oracle GoldenGate replication and configuring an Oracle GoldenGate administrator

82.2 Summary of DBMS_GOLDENGATE_ADM Subprograms

Table 82-1 DBMS_GOLDENGATE_ADM Package Subprograms

Subprogram	Description
ADD_AUTO_CDR Procedure	Configures Oracle GoldenGate automatic conflict detection and resolution for a table
ADD_AUTO_CDR_COLUMN_GROUP Procedure	Adds a column group and configures Oracle GoldenGate automatic conflict detection and resolution for the column group
ADD_AUTO_CDR_DELTA_RES Procedure	Configures Oracle GoldenGate automatic conflict detection and delta resolution for the column
ALTER_AUTO_CDR Procedure	Alters the Oracle GoldenGate automatic conflict detection and resolution for a table
ALTER_AUTO_CDR_COLUMN_GROUP Procedure	Alters a column group for Oracle GoldenGate automatic conflict detection and resolution
DELETE_PROCREP_EXCLUSION_OBJ Procedure	Deletes a database object from the exclusion list for Oracle GoldenGate procedural replication

Table 82-1 (Cont.) DBMS_GOLDENGATE_ADM Package Subprograms

Subprogram	Description
GG_PROCEDURE_REPLICATION_ON Function	Returns 1 if Oracle GoldenGate procedural replication is enabled and returns 0 if it is disabled
INSERT_PROCREP_EXCLUSION_OBJ Procedure	Inserts a database object into the exclusion list for Oracle GoldenGate procedural replication
PURGE_TOMBSTONES Procedure	Purges rows that were deleted before the specified timestamp from the tombstone table
REMOVE_AUTO_CDR Procedure	Removes Oracle GoldenGate automatic conflict detection and resolution for a table
REMOVE_AUTO_CDR_COLUMN_GROUP Procedure	Removes a column group that was configured for Oracle GoldenGate automatic conflict detection and resolution
REMOVE_AUTO_CDR_DELTA_RES Procedure	Removes Oracle GoldenGate automatic conflict detection and delta resolution for the column

> **Note:**
>
> All procedures commit unless specified otherwise.

82.2.1 ADD_AUTO_CDR Procedure

This procedure configures Oracle GoldenGate automatic conflict detection and resolution for a table.

The conflict detection and resolution configured by this procedure is based on the timestamp of the changes. The procedure adds one or more hidden columns of `TIMESTAMP` type to the table, and each hidden column is counted against the limit of 1,000 columns for each table.

The procedure automatically places the columns in the table into a default column group and into an unconditional supplemental log group, excluding nonscalar columns. To create column groups that include a subset of the columns in the table, use the `ADD_AUTO_CDR_COLUMN_GROUP` procedure in this package.

This procedure is overloaded. One version of this procedure contains the `additional_options` parameter, and the other does not.

Syntax

```
DBMS_GOLDENGATE_ADM.ADD_AUTO_CDR(
   schema_name             IN VARCHAR2,
   table_name              IN VARCHAR2,
   resolution_granularity  IN VARCHAR2 DEFAULT 'ROW',
   existing_data_timestamp IN TIMESTAMP WITH TIME ZONE DEFAULT
'SYSTIMESTAMP',
   tombstone_deletes       IN BOOLEAN DEFAULT TRUE,
   fetchcols               IN BOOLEAN DEFAULT TRUE,
```

```
   record_conflicts        IN BOOLEAN DEFAULT TRUE,
   use_custom_handlers     IN BINARY_INTEGER DEFAULT 0);

DBMS_GOLDENGATE_ADM.ADD_AUTO_CDR(
   schema_name             IN VARCHAR2,
   table_name              IN VARCHAR2,
   resolution_granularity  IN VARCHAR2 DEFAULT 'ROW',
   existing_data_timestamp IN TIMESTAMP WITH TIME ZONE DEFAULT
'SYSTIMESTAMP',
   tombstone_deletes       IN BOOLEAN DEFAULT TRUE,
   fetchcols               IN BOOLEAN DEFAULT TRUE,
   record_conflicts        IN BOOLEAN DEFAULT TRUE,
   use_custom_handlers     IN BINARY_INTEGER DEFAULT 0,
   additional_options      IN BINARY_INTEGER);
```

Parameters

Table 82-2 ADD_AUTO_CDR Procedure Parameters

Parameter	Description
schema_name	The name of the table's schema.
table_name	The name of the table.
resolution_granularity	ROW, the default, adds one hidden TIMESTAMP column for the row and one hidden TIMESTAMP column for each LOB column. COLUMN adds one hidden TIMESTAMP column for each column in the table.
existing_data_timestamp	Timestamp to assign to existing rows. If NULL, then the current system timestamp is used. If a time is specified, and the operating system time zone is not a valid Oracle time zone, then Oracle uses UTC as the default value.
tombstone_deletes	TRUE, the default, tracks deleted rows in a tombstone table. Tracking deleted rows might be required to detect and resolve some conflicts, but tracking deleted rows requires additional database resources. FALSE does not track deleted rows in a tombstone table.
fetchcols	TRUE, the default, fetches the value of LOBs during conflict detection and resolution. Fetching LOBs can be an expensive operation. FALSE does not fetch the value of LOBs during conflict detection and resolution.
record_conflicts	TRUE, the default, records the conflict in the DBA_APPLY_ERROR and DBA_APPLY_ERROR_MESSAGES views. FALSE does not record the conflict.

Table 82-2 (Cont.) ADD_AUTO_CDR Procedure Parameters

Parameter	Description
use_custom_handlers	0, the default, indicates that automatic conflict handlers are used. 1 indicates that automatic conflict handlers are not used and that a custom error handler must be specified using the SET_DML_HANDLER procedure in the DBMS_APPLY_ADM package.
additional_options	0 indicates NONE. You can also use the DBMS_GOLDENGATE_ADM.DBMS_GOLDENGATE_ADM.ADDITIONAL_OPTIONS_NONE constant. 1 indicates EARLIEST_TIMESTAMP_RESOLUTION. In earliest timestamp resolution, the earliest timestamp is used for conflict resolution instead of the latest timestamp. You can also use the DBMS_GOLDENGATE_ADM.ADDITIONAL_OPTIONS_EARLIEST_TIMESTAMP constant. 2 indicates DELETE_ALWAYS_WINS. In delete always wins, when there is a conflict between a delete operation and another operation, the delete operation succeeds and the other operation is discarded. You can also use the DBMS_GOLDENGATE_ADM.ADDITIONAL_OPTIONS_DELETE_ALWAYS_WINS constant. 4 indicates IGNORE_GLOBAL_SITE_PRIORITY. In ignore global site priority, the locally defined resolution is used for the table even if global site priority is set in the Oracle GoldenGate replicat file. You can also use the DBMS_GOLDENGATE_ADM.ADDITIONAL_OPTIONS_IGNORE_GLOBAL_SITE_PRIORITY constant. 8 indicates ADD_KEY_VERSION. Use this option to add a version number with TIMESTAMP data type to handle delete conflicts. You can also use the DBMS_GOLDENGATE_ADM.ADDITIONAL_OPTIONS_ADD_KEY_VERSION constant. Add the options together to use more than one option. For example, to use earliest timestamp resolution and delete always wins, use 3.

Example

The following example illustrates how to use bitmask:

```
SQL> EXECUTE dbms_goldengate_adm.add_auto_cdr('scott','table1',
   additional_options =>
   dbms_goldengate_adm.additional_options_delete_always_wins +
      dbms_goldengate_adm.additional_options_add_key_version,
    record_conflicts => TRUE);
```

82.2.2 ADD_AUTO_CDR_COLUMN_GROUP Procedure

This procedure adds a column group to a table that is configured for Oracle GoldenGate automatic conflict detection and resolution.

For a table that has been configured for timestamp conflict detection and resolution, this procedure adds a column group that includes a specified subset of columns in the table. Any columns in the table that are not part of a column group remain in the default column group for the table.

When you add a column group to a table, conflict detection and resolution is performed on the columns in the column group separately from the other columns in the table. Column groups enable different databases to update different columns in the same row at nearly the same time without causing a conflict.

For example, a replicated table that contains employee information might have a salary column and a bonus column as well as other columns that identify the employee and a location column for the employees office number. Assume that one department in the company updates its database to change the employee's salary while another department updates its database to change the employee's location. If the salary and bonus columns are in a column group, these changes are applied to the replicated table in each database without requiring conflict resolution.

The procedure automatically places the columns in the column group into an unconditional supplemental log group, excluding nonscalar columns.

Before this procedure can be run on a table, the `DBMS_GOLDENGATE_ADM.ADD_AUTO_CDR` procedure must be run in the table with `ROW` specified for the `resolution_granularity` parameter.

Syntax

```
DBMS_GOLDENGATE_ADM.ADD_AUTO_CDR_COLUMN_GROUP(
   schema_name             IN VARCHAR2,
   table_name              IN VARCHAR2,
   column_list             IN VARCHAR2,
   column_group_name       IN VARCHAR2 DEFAULT NULL,
   existing_data_timestamp IN TIMESTAMP WITH TIME ZONE DEFAULT NULL);
```

Parameters

Table 82-3 ADD_AUTO_CDR_COLUMN_GROUP Procedure Parameters

Parameter	Description
`schema_name`	The name of the table's schema.
`table_name`	The name of the table.
`column_list`	Group of columns for which the conflict detection and resolution is configured. Specify the columns in a comma-separated list. The same column cannot be in more than one column group. Also, the same column cannot be in a column group and specified in a delta resolution.
`column_group_name`	The name of the column group. If `NULL`, the column group name is system generated.

Table 82-3 (Cont.) ADD_AUTO_CDR_COLUMN_GROUP Procedure Parameters

Parameter	Description
existing_data_timestamp	The time value for the added TIMESTAMP columns for existing table data.

82.2.3 ADD_AUTO_CDR_DELTA_RES Procedure

This procedure configures Oracle GoldenGate automatic conflict detection and delta resolution for the column.

The resolution method does not depend on a timestamp or an extra resolution column. With delta conflict resolution, the conflict is resolved by adding the difference between the new and old values in the LCR to the value in the table. For example, if a bank balance is updated at two sites concurrently, then the converged value accounts for all debits and credits. This resolution method is generally used for financial data such as an account balance.

The procedure automatically places the column into an unconditional supplemental log group.

Before this procedure can be run on a table, the DBMS_GOLDENGATE_ADM.ADD_AUTO_CDR procedure must be run in the table with ROW specified for the resolution_granularity parameter.

Syntax

```
DBMS_GOLDENGATE_ADM.ADD_AUTO_CDR_DELTA_RES(
   schema_name IN VARCHAR2,
   table_name  IN VARCHAR2,
   column_name IN VARCHAR2);
```

Parameters

Table 82-4 ADD_AUTO_CDR_DELTA_RES Procedure Parameters

Parameter	Description
schema_name	The name of the table's schema.
table_name	The name of the table.
column_name	The name of the column. The specified column must be a NUMBER or FLOAT data type column. The same column cannot be in a column group.

82.2.4 ALTER_AUTO_CDR Procedure

This procedure alters the Oracle GoldenGate automatic conflict detection and resolution for a table.

This procedure is overloaded. One version of this procedure contains the additional_options parameter, and the other does not.

Syntax

```
DBMS_GOLDENGATE_ADM.ALTER_AUTO_CDR(
   schema_name             IN VARCHAR2,
   table_name              IN VARCHAR2,
   tombstone_deletes       IN BOOLEAN DEFAULT TRUE,
   fetchcols               IN BOOLEAN DEFAULT TRUE,
   record_conflicts        IN BOOLEAN DEFAULT TRUE,
   use_custom_handlers     IN BINARY_INTEGER DEFAULT 0);

DBMS_GOLDENGATE_ADM.ALTER_AUTO_CDR(
   schema_name             IN VARCHAR2,
   table_name              IN VARCHAR2,
   tombstone_deletes       IN BOOLEAN DEFAULT TRUE,
   fetchcols               IN BOOLEAN DEFAULT TRUE,
   record_conflicts        IN BOOLEAN DEFAULT TRUE,
   use_custom_handlers     IN BINARY_INTEGER DEFAULT 0,
   additional_options      IN BINARY_INTEGER);
```

Parameters

Table 82-5 ALTER_AUTO_CDR Procedure Parameters

Parameter	Description
schema_name	The name of the table's schema.
table_name	The name of the table.
tombstone_deletes	TRUE tracks deleted rows in a tombstone table. Tracking deleted rows might be required to detect and resolve some conflicts, but tracking deleted rows requires additional database resources. FALSE does not track deleted rows in a tombstone table. NULL retains the current setting for the parameter.
fetchcols	TRUE fetches the value of nonscalar columns during conflict detection and resolution. FALSE does not fetch the value of nonscalar columns during conflict detection and resolution. NULL retains the current setting for the parameter.
record_conflicts	TRUE records the conflict. FALSE does not record the conflict. NULL retains the current setting for the parameter.
use_custom_handlers	0, default, indicates that automatic conflict handlers are used. 1 indicates that automatic conflict handlers are not used and that a custom error handler must be specified using the SET_DML_HANDLER procedure in the DBMS_APPLY_ADM package. NULL, the default, retains the current setting for the parameter.

Table 82-5 (Cont.) ALTER_AUTO_CDR Procedure Parameters

Parameter	Description
additional_options	A bit mask that indicates which of six types of actions to follow: • 0 - no changes are made from any previous settings. You can also use the DBMS_GOLDENGATE_ADM.ADDITIONAL_OPTIONS_NONE constant. • 1 - sets earliest timestamp, but clears all other options/ bits. You can also use the DBMS_GOLDENGATE_ADM.EARLIEST_TIMESTAMP_RESOLUTION constant. • 2 - sets delete always wins, but clears all other options/ bits. You can also use the DBMS_GOLDENGATE_ADM.ADDITIONAL_OPTIONS_DELETE_ALWAYS_WINS constant. • 4 - indicates IGNORE_GLOBAL_SITE_PRIORITY. When you specify this option, then use local site resolution configuration for the table, even if the global site priority is set in the Oracle GoldenGate replicat file. You can also use the DBMS_GOLDENGATE_ADM.ADDITIONAL_OPTIONS_IGNORE_GLOBAL_SITE_PRIORITY constant. • 8 - indicates ADD_KEY_VERSION. Use this option to add a version number with TIMESTAMP data type to handle delete conflicts. You can also use the DBMS_GOLDENGATE_ADM.ADDITIONAL_OPTIONS_ADD_KEY_VERSION constant. • 16 - clears all. You can also use the DBMS_GOLDENGATE_ADM.ADDITIONAL_OPTIONS_CLEAR_OPTIONS constant. **Note:** • Any combination of 1,2, 4, and 8 are possible. • Any combination that include 1 or 2 will implicitly set 8. You can add the options together to use more than one option. For example: If the previously used option was DELETE_ALWAYS_WINS, then when you specify a value of 1 for additional_options, EARLIEST_TIMESTAMP_RESOLUTION and 16 means clear all options. As a result, there are no additional options set.

82.2.5 ALTER_AUTO_CDR_COLUMN_GROUP Procedure

This procedure alters a column group for Oracle GoldenGate automatic conflict detection and resolution.

Syntax

```
DBMS_GOLDENGATE_ADM.ALTER_AUTO_CDR_COLUMN_GROUP(
   schema_name        IN VARCHAR2,
   table_name         IN VARCHAR2,
   column_group_name  IN VARCHAR2,
   add_column_list    IN VARCHAR2,
   remove_column_list IN VARCHAR2);
```

Parameters

Table 82-6 ALTER_AUTO_CDR_COLUMN_GROUP Procedure Parameters

Parameter	Description
schema_name	The name of the table's schema.
table_name	The name of the table.
column_group_name	The name of the column group.
add_column_list	A comma-separated list of columns to add to the column group.
remove_column_list	A comma-separated list of columns to remove from the column group.

82.2.6 DELETE_PROCREP_EXCLUSION_OBJ Procedure

This procedure deletes a database object from the exclusion list for Oracle GoldenGate procedural replication.

When a database object is on the exclusion list for Oracle GoldenGate procedural replication, execution of subprogram in the package is not replicated if the subprogram operates on the excluded object. For example, if `hr.employees` is an excluded database object for the `DBMS_REDEFINITION` package, then an execution of the `DBMS_REDEFINITION.START_REDEF_TABLE` procedure on the `hr.employees` table is not replicated.

> **Caution:**
>
> Run the `DELETE_PROCREP_EXCLUSION_OBJ` procedure only under the direction of Oracle Support.

Syntax

```
DBMS_GOLDENGATE_ADM.DELETE_PROCREP_EXCLUSION_OBJ(
   package_owner     IN VARCHAR2 DEFAULT NULL,
   package_name      IN VARCHAR2 DEFAULT NULL,
   object_owner      IN VARCHAR2 DEFAULT NULL,
   object_name       IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 82-7 DELETE_PROCREP_EXCLUSION_OBJ Procedure Parameters

Parameter	Description
package_owner	The owner of the package.
package_name	The name of the package.
object_owner	The owner of the object.
object_name	The name of the object.

82.2.7 GG_PROCEDURE_REPLICATION_ON Function

This function returns 1 if Oracle GoldenGate procedural replication is enabled and returns 0 if it is disabled.

Syntax

```
DBMS_GOLDENGATE_ADM.GG_PROCEDURE_REPLICATION_ON
RETURN NUMBER;
```

82.2.8 INSERT_PROCREP_EXCLUSION_OBJ Procedure

This procedure inserts a database object into the exclusion list for Oracle GoldenGate procedural replication.

When a database object is on the exclusion list for Oracle GoldenGate procedural replication, execution of subprogram in the package is not replicated if the subprogram operates on the excluded object. For example, if `hr.employees` is an excluded database object for the `DBMS_REDEFINITION` package, then an execution of the `DBMS_REDEFINITION.START_REDEF_TABLE` procedure on the `hr.employees` table is not replicated.

> **Caution:**
>
> Run the `INSERT_PROCREP_EXCLUSION_OBJ` procedure only under the direction of Oracle Support.

Syntax

```
DBMS_GOLDENGATE_ADM.INSERT_PROCREP_EXCLUSION_OBJ(
   package_owner     IN VARCHAR2 DEFAULT NULL,
   package_name      IN VARCHAR2 DEFAULT NULL,
   object_owner      IN VARCHAR2 DEFAULT NULL,
   object_name       IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 82-8 INSERT_PROCREP_EXCLUSION_OBJ Procedure Parameters

Parameter	Description
package_owner	The owner of the package.
package_name	The name of the package.
object_owner	The owner of the object.
object_name	The name of the object.

82.2.9 PURGE_TOMBSTONES Procedure

This procedure purges rows that were deleted before the specified timestamp from the tombstone table.

Syntax

```
DBMS_GOLDENGATE_ADM.PURGE_TOMBSTONES(
   purge_timestamp IN TIMESTAMP WITH TIME ZONE);
```

Parameters

Table 82-9 PURGE_TOMBSTONES Procedure Parameters

Parameter	Description
purge_timestamp	The timestamp before which records are purged.

82.2.10 REMOVE_AUTO_CDR Procedure

This procedure removes Oracle GoldenGate automatic conflict detection and resolution for a table.

Syntax

```
DBMS_GOLDENGATE_ADM.REMOVE_AUTO_CDR(
   schema_name             IN VARCHAR2,
   table_name              IN VARCHAR2);
```

Parameters

Table 82-10 REMOVE_AUTO_CDR Procedure Parameters

Parameter	Description
schema_name	The name of the table's schema.
table_name	The name of the table.

82.2.11 REMOVE_AUTO_CDR_COLUMN_GROUP Procedure

This procedure removes a column group that was configured for Oracle GoldenGate automatic conflict detection and resolution.

Syntax

```
DBMS_GOLDENGATE_ADM.REMOVE_AUTO_CDR_COLUMN_GROUP(
   schema_name             IN VARCHAR2,
   table_name              IN VARCHAR2,
   column_group_name       IN VARCHAR2);
```

Parameters

Table 82-11 REMOVE_AUTO_CDR_COLUMN_GROUP Procedure Parameters

Parameter	Description
schema_name	The name of the table's schema.
table_name	The name of the table.
column_group_name	The name of the column group.

82.2.12 REMOVE_AUTO_CDR_DELTA_RES Procedure

This procedure removes Oracle GoldenGate automatic conflict detection and delta resolution for the column.

Syntax

```
DBMS_GOLDENGATE_ADM.REMOVE_AUTO_CDR_DELTA_RES(
   schema_name IN VARCHAR2,
   table_name  IN VARCHAR2,
   column_name IN VARCHAR2);
```

Parameters

Table 82-12 REMOVE_AUTO_CDR_DELTA_RES Procedure Parameters

Parameter	Description
schema_name	The name of the table's schema.
table_name	The name of the table.
column_name	The name of the column.

83
DBMS_GOLDENGATE_AUTH

The DBMS_GOLDENGATE_AUTH package provides subprograms for granting privileges to and revoking privileges from GoldenGate administrators.

This chapter contains the following topics:

- Overview
- Security Model
- Summary of DBMS_GOLDENGATE_AUTH Subprograms

> **See Also:**
>
> GRANT_ADMIN_PRIVILEGE Procedure in the DBMS_XSTREAM_AUTH package

83.1 DBMS_GOLDENGATE_AUTH Overview

This package provides subprograms for granting privileges to GoldenGate administrators and revoking privileges from GoldenGate administrators. A GoldenGate administrator manages an integrated GoldenGate and XStream Out configuration.

GoldenGate administrators can be used in a multitenant container database (CDB). A CDB is an Oracle database that includes zero, one, or many user-created pluggable databases (PDBs).

> **See Also:**
>
> - GRANT_ADMIN_PRIVILEGE Procedure in the DBMS_XSTREAM_AUTH package
> - *Oracle Database XStream Guide*
> - *Oracle Database Concepts* for more information about CDBs and PDBs

83.2 DBMS_GOLDENGATE_AUTH Security Model

Security on this package can be controlled by granting EXECUTE on this package to selected users or roles, or by granting EXECUTE_CATALOG_ROLE to selected users or roles.

The user executing the subprograms in the DBMS_GOLDENGATE_AUTH package must have SYSDBA administrative privilege, and the user must exercise the privilege using AS SYSDBA at connect time.

If subprograms in the package are run from within a stored procedure, then the user who runs the subprograms must be granted `EXECUTE` privilege on the package directly. It cannot be granted through a role.

To ensure that the user who runs the subprograms in this package has the necessary privileges, connect as an administrative user who can create users, grant privileges, and create tablespaces when using this package.

83.3 Summary of DBMS_GOLDENGATE_AUTH Subprograms

The DBMS_XSTREAM_AUTH package includes the GRANT_ADMIN_PRIVILEGE procedure and REVOKE_ADMIN_PRIVILEGE procedure subprograms.

Table 83-1 DBMS_GOLDENGATE_AUTH Package Subprograms

Subprogram	Description
GRANT_ADMIN_PRIVILEGE Procedure	Either grants the privileges needed by a user to be a GoldenGate administrator directly, or generates a script that grants these privileges
REVOKE_ADMIN_PRIVILEGE Procedure	Either revokes GoldenGate administrator privileges from a user directly, or generates a script that revokes these privileges

> **Note:**
>
> All subprograms commit unless specified otherwise.

83.3.1 GRANT_ADMIN_PRIVILEGE Procedure

This procedure grants the privileges needed by a user to be a GoldenGate administrator.

> **See Also:**
>
> GRANT_ADMIN_PRIVILEGE Procedure in the DBMS_XSTREAM_AUTH package

Syntax

```
DBMS_GOLDENGATE_AUTH.GRANT_ADMIN_PRIVILEGE(
   grantee                    IN  VARCHAR2,
   privilege_type             IN  VARCHAR2  DEFAULT '*',
   grant_select_privileges    IN  BOOLEAN   DEFAULT TRUE,
   do_grants                  IN  BOOLEAN   DEFAULT TRUE,
   file_name                  IN  VARCHAR2  DEFAULT NULL,
   directory_name             IN  VARCHAR2  DEFAULT NULL
```

```
  grant_optional_privileges  IN  VARCHAR2  DEFAULT NULL,
  container                  IN  VARCHAR2  DEFAULT 'CURRENT');
```

Parameters

Table 83-2 GRANT_ADMIN_PRIVILEGE Procedure Parameters

Parameter	Description
grantee	The user to whom privileges are granted
privilege_type	Specify one of the following values: • CAPTURE Specifying CAPTURE grants the minimum privileges required by the user to administer Oracle GoldenGate integrated extract. • APPLY Specifying APPLY grants the minimum privileges required by the user to administer Oracle GoldenGate integrated replicat. • * Specifying * grants the minimum privileges required by the user to administer Oracle GoldenGate integrated extract and Oracle GoldenGate integrated replicat.
grant_select_privileges	If TRUE, then the procedure grants a set of privileges, including SELECT_CATALOG_ROLE, to the user. This setting is recommended for GoldenGate administrators. If FALSE, then the procedure does not grant the set of privileges to the user. SELECT_CATALOG_ROLE enables the user to select from the data dictionary.
do_grants	If TRUE, then the procedure grants the privileges to the specified grantee directly, and adds the grantee to the DBA_GOLDENGATE_PRIVILEGES data dictionary view. If the user already has an entry in this data dictionary view, then the procedure does not make another entry, and no error is raised. If TRUE and any of the grant statements fails, then the procedure raises an error. If FALSE, then the procedure does not grant the privileges to the specified grantee directly, and does not add the grantee to the DBA_GOLDENGATE_PRIVILEGES data dictionary view. You specify FALSE when the procedure is generating a file that you will run later. If you specify FALSE and either the file_name or directory_name parameter is NULL, then the procedure raises an error. Note: It is recommended that do_grants be set to TRUE because many APIs check for the presence of a user in the DBA_GOLDENGATE_PRIVILEGES view, which will not be populated if do_grants is set to FALSE.
file_name	The name of the file generated by the procedure. The file contains all of the statements that grant the privileges. If a file with the specified file name exists in the specified directory name, then the grant statements are appended to the existing file. If NULL, then the procedure does not generate a file.

Table 83-2 (Cont.) GRANT_ADMIN_PRIVILEGE Procedure Parameters

Parameter	Description
directory_name	The directory into which the generated file is placed. The specified directory must be a directory object created using the SQL statement CREATE DIRECTORY. If you specify a directory, then the user who invokes the procedure must have the WRITE privilege on the directory object. If the file_name parameter is NULL, then this parameter is ignored, and the procedure does not generate a file. If NULL and the file_name parameter is non-NULL, then the procedure raises an error.
grant_optional_privileges	A comma-separated list of optional privileges to grant to the grantee. You can specify the following roles and privileges: • XDBADMIN • DV_XSTREAM_ADMIN • DV_GOLDENGATE_ADMIN • EXEMPT_ACCESS_POLICY • EXEMPT_REDACTION_POLICY
container	If CURRENT, then grants privileges to the grantee only in the container where the procedure is invoked. CURRENT can be specified while connected to the root or to a PDB. If ALL, then grants privileges to the grantee in all containers in the CDB and all PDBs created after the procedure is invoked. To specify ALL, the procedure must be invoked in the root by a common user. If a container name, then grants privileges to the grantee only in the specified container. To specify root, use CDB$ROOT while connected to the root. To specify a PDB, the procedure must be invoked in the root. **Note:** This parameter only applies to CDBs.

Usage Notes

The user who runs the procedure must be an administrative user who can grant privileges to other users.

Specifically, the procedure grants the following privileges to the specified user:

- The RESTRICTED SESSION system privilege
- EXECUTE on the following packages:
  - DBMS_APPLY_ADM
  - DBMS_AQ
  - DBMS_AQADM
  - DBMS_AQIN
  - DBMS_AQELM
  - DBMS_CAPTURE_ADM
  - DBMS_FLASHBACK
  - DBMS_LOCK
  - DBMS_PROPAGATION_ADM

  - DBMS_RULE_ADM
  - DBMS_TRANSFORM
  - DBMS_XSTREAM_ADM
- Privileges to enqueue messages into and dequeue messages from any queue
- Privileges to manage any queue
- Privileges to create, alter, and execute any of the following types of objects in the user's own schema and in other schemas:
  - Evaluation contexts
  - Rule sets
  - Rules

  In addition, the grantee can grant these privileges to other users.
- SELECT_CATALOG_ROLE
- SELECT or READ privilege on data dictionary views related to GoldenGate and Oracle Replication
- The ability to allow a remote GoldenGate administrator to perform administrative actions through a database link by connecting to the grantee

  This ability is enabled by running the GRANT_REMOTE_ADMIN_ACCESS procedure in this package.

> **Note:**
>
> This procedure grants only the privileges necessary to configure and administer a GoldenGate environment. You can grant additional privileges to the grantee if necessary.

> **See Also:**
>
> GRANT_ADMIN_PRIVILEGE Procedure in the DBMS_XSTREAM_AUTH package

83.3.2 REVOKE_ADMIN_PRIVILEGE Procedure

This procedure revokes GoldenGate administrator privileges from a user.

Syntax

```
DBMS_GOLDENGATE_AUTH.REVOKE_ADMIN_PRIVILEGE(
   grantee                     IN  VARCHAR2,
   privilege_type              IN  VARCHAR2  DEFAULT '*',
   revoke_select_privileges    IN  BOOLEAN   DEFAULT FALSE,
   do_revokes                  IN  BOOLEAN   DEFAULT TRUE,
   file_name                   IN  VARCHAR2  DEFAULT NULL,
   directory_name              IN  VARCHAR2  DEFAULT NULL
   revoke_optional_privileges  IN  VARCHAR2  DEFAULT NULL,
   container                   IN  VARCHAR2  DEFAULT 'CURRENT');
```

Parameters

Table 83-3 *REVOKE_ADMIN_PRIVILEGE Procedure Parameters*

Parameter	Description
grantee	The user from whom privileges are revoked
privilege_type	Specify one of the following values: • CAPTURE Specifying CAPTURE revokes the minimum privileges required by the user to administer Oracle GoldenGate integrated extract. • APPLY Specifying APPLY revokes the minimum privileges required by the user to administer Oracle GoldenGate integrated replicat. • * Specifying * revokes the minimum privileges required by the user to administer Oracle GoldenGate integrated extract and Oracle GoldenGate integrated replicat.
revoke_select_privileges	If TRUE, then the procedure revokes SELECT_CATALOG_ROLE from the user. If FALSE, then the procedure does not revoke SELECT_CATALOG_ROLE to the user. SELECT_CATALOG_ROLE enables the user to select from the data dictionary.
do_revokes	If TRUE, then the procedure revokes the privileges from the specified user directly, and removes the user from the DBA_XSTREAM_ADMINISTRATOR data dictionary view. If the user does not have a record in this data dictionary view, then the procedure does not remove a record from the view, and no error is raised. If TRUE and any of the revoke statements fails, then the procedure raises an error. A revoke statement fails if the user is not granted the privilege that is being revoked. If FALSE, then the procedure does not revoke the privileges from the specified user directly, and does not remove the user from the DBA_XSTREAM_ADMINISTRATOR data dictionary view. You specify FALSE when the procedure is generating a file that you will run later. If you specify FALSE and either the file_name or directory_name parameter is NULL, then the procedure does not raise an error.
file_name	The name of the file generated by this procedure. The file contains all of the statements that revoke the privileges. If a file with the specified file name exists in the specified directory name, then the revoke statements are appended to the existing file. If NULL, then the procedure does not generate a file.

Table 83-3 (Cont.) *REVOKE_ADMIN_PRIVILEGE Procedure Parameters*

Parameter	Description
`directory_name`	The directory into which the generated file is placed. The specified directory must be a directory object created using the SQL statement `CREATE DIRECTORY`. If you specify a directory, then the user who invokes the procedure must have the `WRITE` privilege on the directory object. If the `file_name` parameter is `NULL`, then this parameter is ignored, and the procedure does not generate a file. If `NULL` and the `file_name` parameter is non-`NULL`, then the procedure raises an error.
`revoke_optional_privileges`	A comma-separated list of optional privileges to revoke from the grantee, such as the `DV_XSTREAM_ADMIN` and `DV_GOLDENGATE_ADMIN` privileges
`container`	If `CURRENT`, then revokes privileges from the grantee only in the container where the procedure is invoked. `CURRENT` can be specified while connected to the root or to a PDB. If `ALL`, then revokes privileges from the grantee in all containers in the CDB. To specify `ALL`, the procedure must be invoked in the root. If a container name, then revokes privileges from the grantee only in the specified container. To specify root, use `CDB$ROOT` while connected to the root. To specify a PDB, the procedure must be invoked in the root. **Note:** This parameter only applies to CDBs.

Usage Notes

The user who runs this procedure must be an administrative user who can revoke privileges from other users. Specifically, this procedure revokes the privileges granted by running the `GRANT_ADMIN_PRIVILEGE` procedure in this package.

>
> "GRANT_ADMIN_PRIVILEGE Procedure"

84
DBMS_HADOOP

The DBMS_HADOOP package provides a PL/SQL procedure called CREATE_EXTDDL_FOR_HIVE(), that creates an Oracle external table for a given hive table.

Big Data SQL needs to be correctly set up for DBMS_HADOOP to work.

This chapter contains the following topics:

- DBMS_HADOOP Overview
- DBMS_HADOOP Security Model
- Summary of DBMS_HADOOP Subprograms

84.1 DBMS_HADOOP Overview

The DBMS_HADOOP package provides two procedures for creating an Oracle external table and for synchronizing the Oracle external table partitions.

These procedures are:

- CREATE_EXTDDL_FOR_HIVE() — creates an Oracle external table for a given hive table
- SYNCHRONIZE_PARTITIONS_FOR_HIVE() — helps to synchronize the Oracle external table partitions with those in the corresponding hive table

84.2 DBMS_HADOOP Security Model

Users must have ALTER privileges on the table for modifying external table parameters. In addition the ALTER privileges, users must have READ privileges for the directory object that contains the external data source and WRITE privileges for the directory objects containing bad, log, and discard files.

Similar privileges are applicable to the partitioned external tables.

84.3 Summary of DBMS_HADOOP Subprograms

DBMS_HADOOP includes the CREATE_EXTDDL_FOR_HIVE procedure and SYNC_PARTITIONS_FOR_HIVE procedure subprograms.

Table 84-1 DBMS_HADOOP Subprograms

Subprogram	Description
CREATE_EXTDDL_FOR_HIVE Procedure	Given a hive table name, creates a text of DDL that can be executed to create an external table corresponding to the hive table

Table 84-1 (Cont.) DBMS_HADOOP Subprograms

Subprogram	Description
CREATE_HYBRID_PARTNED_TABLE Procedure	Merges a given partitioned Hive table with an Oracle partitioned table, and replaces it with the merged table.
SYNCHRONIZE_PARTITIONS_FOR_HIVE Procedure	Synchronizes the existing partitioning definition of a hive table in Oracle catalog

84.3.1 CREATE_EXTDDL_FOR_HIVE Procedure

This procedure creates an Oracle external table for a given hive table.

Syntax

```
DBMS_HADOOP.CREATE_EXTDDL_FOR_HIVE (
   cluster_id         IN  VARCHAR2,
   db_name            IN  VARCHAR2 := NULL,
   hive_table_name    IN  VARCHAR2,
   hive_partition     IN  BOOLEAN,
   table_name         IN  VARCHAR2 := NULL,
   perform_DDL        IN  BOOLEAN := FALSE,
   text_of_DDL        OUT CLOB);
```

Parameters

Table 84-2 CREATE_EXTDDL_FOR_HIVE Procedure Parameters

Parameter	Description
cluster_id	Hadoop cluster ID
hive_db_name	Database where the hive table is located
hive_table_name	Name of the hive table
hive_partition	If this argument is TRUE and if the original hive table is partitioned, the corresponding Oracle external table will also be partitioned using the same partition key(s). If the original hive table is not partitioned, hive_partition=TRUE has no effect. If hive_partition=FALSE, the corresponding Oracle external table will not be partitioned even if the original hive table is partitioned.
table_name	Name of the Oracle external table
perform_DDL	If this argument is TRUE, the external table will be automatically created. Otherwise, only the textual representation of the DDL statement will be generated and returned in text_of_DDL .
text_of_DDL	If the argument perform_DDL is FALSE, only the textual representation of the DDL statement will be generated and returned in text_of_DDL .

84.3.2 CREATE_HYBRID_PARTNED_TABLE Procedure

This procedure merges the partitioned Hive table with an Oracle partitioned table, and replace it with the merged table.

Syntax

```
DBMS_HADOOP.CREATE_HYBRID_PARTNED_TABLE (
   cluster_id                    IN     VARCHAR2,
   db_name            IN    VARCHAR2,
   hive_table_name    IN     VARCHAR2,
   table_name                    IN     VARCHAR2,
   table_owner        IN     VARCHAR2,
   perform_ddl                IN     BOOLEAN := TRUE,
   text_of_ddl        OUT    CLOB);
```

Parameters

Table 84-3 CREATE_HYBRID_PARTNED_TABLE Procedure Parameters

Parameter	Description
cluster_id	Hadoop cluster ID
db_name	Database where the partitioned Hive table is located
hive_table_name	Name of the partitioned Hive table
table_name	Name of the partitioned Oracle table
table_owner	The owner of the partitioned Oracle table
perform_DDL	If the value of this parameter is TRUE, the external table is automatically created. If the value of this parameter is FALSE, only the textual representation of the DDL statement is generated and returned in text_of_DDL.
text_of_DDL	If the argument perform_DDL is FALSE, only the textual representation of the DDL statement is generated and returned in text_of_DDL.

84.3.3 SYNCHRONIZE_PARTITIONS_FOR_HIVE Procedure

This procedure synchronizes the Oracle external table partitions with those in the corresponding hive table.

Syntax

```
DBMS_HADOOP.SYNCHRONIZE_PARTITIONS_FOR_HIVE (
   table_name     IN  VARCHAR2,
   table_owner    IN  VARCHAR2);
```

Parameters

Table 84-4 SYNCHRONIZE_PARTITIONS_FOR_HIVE Procedure Parameters

Parameter	Description
`table_name`	Oracle external table
`table_owner`	Schema name

85
DBMS_HANG_MANAGER

The DBMS_HANG_MANAGER package provides a method of changing some Hang Manager configuration parameters.

This chapter contains the following topics:

- DBMS_HANG_MANAGER Overview
- DBMS_HANG_MANAGER Security Model
- DBMS_HANG_MANAGER Constants
- DBMS_HANG_MANAGER Exceptions
- Summary of DBMS_HANG_MANAGER Subprograms

85.1 DBMS_HANG_MANAGER Overview

The DBMS_HANG_MANAGER package provides a method of changing some Hang Manager configuration parameters.

Hang Manager is always enabled on all databases, Automatic Storage Management (ASM) disk groups, and single instance systems (when not using Oracle RAC). Hang resolution is enabled on all instances by default except for single instance systems (when not using Oracle RAC) where it is disabled and cannot be enabled at this time.

> **Note:**
>
> The `DBMS_HANG_MANAGER` package is intended for use by database administrators (DBA) only. It is not intended for use by application developers.

85.2 DBMS_HANG_MANAGER Security Model

DBMS_HANG_MANAGER can only be run as the `SYS` user.

85.3 DBMS_HANG_MANAGER Constants

The table in this topic lists DBMS_HANG_MANAGER package constants.

Table 85-1 DBMS_HANG_MANAGER Constants

Name	Type	Value	Description
`RESOLUTION_SCOPE`	`VARCHAR2`	`resolution scope`	Resolution scope parameter name

Table 85-1 (Cont.) DBMS_HANG_MANAGER Constants

Name	Type	Value	Description
SENSITIVITY	VARCHAR2	sensitivity	Sensitivity parameter name
BASE_FILE_SIZE_LIMIT	VARCHAR2	base file size limit	Base file size limit parameter name. The default value of this parameter is 100 MB.
BASE_FILE_SET_COUNT	VARCHAR2	base file set count	Base file set count parameter name. The default value is 5 trace files in the circular trace file set.
LWS_FILE_SIZE_LIMIT	VARCHAR2	long waiting session file size limit	Long waiting session file size limit parameter name. The default value of this parameter is 100 MB.
LWS_FILE_SET_COUNT	VARCHAR2	long waiting session set count	Long waiting session set count parameter name. The default value is 5 trace files in the circular trace file set.
RESOLUTION_SCOPE_PROCESS	VARCHAR2	PROCESS	Enables only session and/or process termination
RESOLUTION_SCOPE_INSTANCE	VARCHAR2	INSTANCE	Enables session, process, and instance termination. The latter is used in specific scenarios. The default value is INSTANCE.
SENSITIVITY_NORMAL	VARCHAR2	NORMAL	Sets various Hang Manager intervals to their default values. The default value is NORMAL.
SENSITIVITY_HIGH	VARCHAR2	HIGH	Sets the various Hang Manager intervals to half of their default values

85.4 DBMS_HANG_MANAGER Exceptions

The table in this topic lists the exceptions raised by the DBMS_HANG_MANAGER package.

Table 85-2 DBMS_HANG_MANAGER Package Exceptions

Exception	Error Code	Description
ERRNUM_INPUT_ERROR	-32706	Invalid user input

Table 85-2 (Cont.) DBMS_HANG_MANAGER Package Exceptions

Exception	Error Code	Description
ERRNUM_INTERNAL_ERROR	-32707	Database experienced an error setting a parameter
ERRNUM_UNSUPPORTED_ERRO R	-32708	Operation is not supported on this instance type

85.5 Summary of DBMS_HANG_MANAGER Subprograms

The DBMS_HANG_MANAGER package includes the SET procedure subprogram.

Table 85-3 DBMS_HANG_MANAGER Package Subprograms

Subprogram	Description
SET Procedure	Sets the specified parameter to the specified value

85.5.1 SET Procedure

This procedure sets the specified parameters to specified values.

Syntax

```
DBMS_HANG_MANAGER.SET (
   pname   IN  VARCHAR2,
   pvalue  IN  VARCHAR2);
```

Parameters

Table 85-4 SET Procedure Parameters

Parameter	Description
pname	Contains the parameter name that needs to be modified
pvalue	Contains the new value for the parameter name specified in pname

86
DBMS_HEAT_MAP

The DBMS_HEAT_MAP package provides an interface to externalize heatmaps at various levels of storage including block, extent, segment, object and tablespace. A second set of subprograms externalize the heatmaps materialized by the background for top N tablespaces.

This chapter contains the following topics:

- Overview
- Security Model
- Summary of DBMS_HEAT_MAP Subprograms

> **See Also:**
>
> - Heat Map in *Oracle Database VLDB and Partitioning Guide*
> - DBMS_ILM
> - DBMS_ILM_ADMIN

86.1 DBMS_HEAT_MAP Overview

To implement your ILM strategy, you can use Heat Map in Oracle Database to track data access and modification. You can also use Automatic Data Optimization (ADO) to automate the compression and movement of data between different tiers of storage within the database.

The Heat Map tracks modification times at the block level, and multiple access statistics at the segment level. Objects in the SYSTEM and SYSAUX tablespaces are not tracked. DBMS_HEAT_MAP gives you access to the Heat Map statistics at various levels - block, extent, segment, object, and tablespace.

86.2 DBMS_HEAT_MAP Security Model

The execution privilege is granted to PUBLIC. Procedures in this package run under the caller security. The user must have ANALYZE privilege on the object.

86.3 Summary of DBMS_HEAT_MAP Subprograms

This table lists and briefly describes the DBMS_HEAT_MAP package subprograms.

Table 86-1 DBMS_HEAT_MAP Package Subprograms

Subprogram	Description
BLOCK_HEAT_MAP Function	Returns last modification time for each block in a table segment
EXTENT_HEAT_MAP Function	Returns the extent level Heat Map statistics for a table segment
OBJECT_HEAT_MAP Function	Returns the minimum, maximum and average access times for all the segments belonging to the object
SEGMENT_HEAT_MAP Procedure	Returns the heatmap attributes for the given segment
TABLESPACE_HEAT_MAP Function	Returns the minimum, maximum and average access times for all the segments in the tablespace

86.3.1 BLOCK_HEAT_MAP Function

This table function returns the last modification time for each block in a table segment. It returns no information for segment types that are not data.

Syntax

```
DBMS_HEAT_MAP.BLOCK_HEAT_MAP (
   owner             IN VARCHAR2,
   segment_name      IN VARCHAR2,
   partition_name    IN VARCHAR2 DEFAULT NULL,
   sort_columnid     IN NUMBER DEFAULT NULL,
   sort_order        IN VARCHAR2 DEFAULT NULL)
RETURN hm_bls_row PIPELINED;
```

Parameters

Table 86-2 *BLOCK_HEAT_MAP Function Parameters*

Parameter	Description
`owner`	Owner of the segment
`segment_name`	Table name of a non-partitioned table or (sub)partition of partitioned table. Returns no rows when table name is specified for a partitioned table.
`partition_name`	Defaults to `NULL`. For a partitioned table, specify the partition or subpartition segment name.
`sort_columnid`	ID of the column on which to sort the output. Valid values 1..9. Invalid values are ignored.
`sort_order`	Defaults to `NULL`. Possible values: `ASC`, `DESC`

Return Values

Table 86-3 *BLOCK_HEAT_MAP Function Return Values (Output Parameters)*

Parameter	Description
owner	Owner of the segment
segment_name	Segment name of the non-partitioned table
partition_name	Partition or subpartition name
tablespace_name	Tablespace containing the segment
file_id	Absolute file number of the block in the segment
relative_fno	Relative file number of the block in the segment
block_id	Block number of the block
write time	Last modification time of the block

86.3.2 EXTENT_HEAT_MAP Function

This table function returns the extent level Heat Map statistics for a table segment. It returns no information for segment types that are not data. Aggregates at extent level, including minimum modification time and maximum modification time, are included.

Syntax

```
DBMS_HEAT_MAP.EXTENT_HEAT_MAP (
   owner             IN VARCHAR2,
   segment_name      IN VARCHAR2,
   partition_name    IN VARCHAR2 DEFAULT NULL,
RETURN hm_els_row PIPELINED;
```

Parameters

Table 86-4 *EXTENT_HEAT_MAP Function Parameters*

Parameter	Description
owner	Owner of the segment
segment_name	Table name of a non-partitioned table or (sub)partition of partitioned table. Returns no rows when table name is specified for a partitioned table.
partition_name	Defaults to NULL. For a partitioned table, specify the partition or subpartition segment name.

Return Values

Table 86-5 *EXTENT_HEAT_MAP Function Return Values (Output Parameters)*

Parameter	Description
owner	Owner of the segment
segment_name	Segment name of the non-partitioned table

Table 86-5 (Cont.) *EXTENT_HEAT_MAP Function Return Values (Output Parameters)*

Parameter	Description
partition_name	Partition or subpartition name
tablespace_name	Tablespace containing the segment
file_id	Absolute file number of the block in the segment
relative_fno	Relative file number of the block in the segment
block_id	Block number of the block
blocks	Number of blocks in the extent
bytes	Number of bytes in the extent
min_writetime	Minimum of last modification time of the block
max_writetime	Maximum of last modification time of the block
avg_writetime	Average of last modification time of the block

86.3.3 OBJECT_HEAT_MAP Function

This table function returns the minimum, maximum and average access times for all the segments belonging to the object.

The object must be a table. The table function raises an error if called on object tables other than table.

Syntax

```
DBMS_HEAT_MAP.OBJECT_HEAT_MAP (
   object_owner      IN VARCHAR2,
   object_name       IN VARCHAR2)
 RETURN hm_object_table PIPELINED;
```

Parameters

Table 86-6 *OBJECT_HEAT_MAP Function Parameters*

Parameter	Description
object_owner	Tablespace containing the segment
object_name	Segment header relative file number

Return Values

Table 86-7 *OBJECT_HEAT_MAP Function Return Values (Output Parameters)*

Parameter	Description
segment_name	Name of the top level segment
partition_name	Name of the partition
tablespace_name	Name of the tablespace
segment_type	Type of segment as in DBA_SEGMENTS.SEGMENT_TYPE

Table 86-7 (Cont.) *OBJECT_HEAT_MAP Function Return Values (Output Parameters)*

Parameter	Description
segment_size	Segment size in bytes
min_writetime	Oldest write time for the segment
max_writetime	Latest write time for the segment
avg_writetime	Average write time for the segment
min_readtime	Oldest read time for the segment
max_readtime	Latest read time for the segment
avg_writetime	Average write time for the segment
min_lookuptime	Oldest index lookup time for the segment
max_lookuptime	Latest index lookup time for the segment
avg_lookuptime	Average index lookup time for the segment
min_ftstime	Oldest full table scan time for the segment
max_ftstime	Latest full table scan time for the segment
avg_ftstime	Average full table scan time for the segment

86.3.4 SEGMENT_HEAT_MAP Procedure

This procedure returns the heatmap attributes for the given segment.

Syntax

```
DBMS_HEAT_MAP.SEGMENT_HEAT_MAP (
   tablespace_id          IN  NUMBER,
   header_file            IN  NUMBER,
   header_block           IN  NUMBER,
   segment_objd           IN  NUMBER,
   min_writetime          OUT DATE,
   max_writetime          OUT DATE,
   avg_writetime          OUT DATE,
   min_readtime           OUT DATE,
   max_readtime           OUT DATE,
   avg_readtime           OUT DATE,
   min_lookuptime         OUT DATE,
   max_lookuptime         OUT DATE,
   avg_lookuptime         OUT DATE,
   min_ftstime            OUT DATE,
   max_ftstime            OUT DATE,
   avg_ftstime            OUT DATE);
```

Parameters

Table 86-8 *SEGMENT_HEAT_MAP Procedure Parameters*

Parameter	Description
tablespace_id	Tablespace containing the segment

Table 86-8 (Cont.) *SEGMENT_HEAT_MAP Procedure Parameters*

Parameter	Description
header_file	Segment header relative file number
header_block	Segment header block number
segment_objd	DATAOBJ of the segment

Return Values

Table 86-9 *SEGMENT_HEAT_MAP Procedure Return Values (Output Parameters)*

Parameter	Description
min_writetime	Oldest write time for the segment
max_writetime	Latest write time for the segment
avg_writetime	Average write time for the segment
min_readtime	Oldest read time for the segment
max_readtime	Latest read time for the segment
avg_writetime	Average write time for the segment
min_lookuptime	Oldest index lookup time for the segment
max_lookuptime	Latest index lookup time for the segment
avg_lookuptime	Average index lookup time for the segment
min_ftstime	Oldest full table scan time for the segment
max_ftstime	Latest full table scan time for the segment
avg_ftstime	Average full table scan time for the segment

86.3.5 TABLESPACE_HEAT_MAP Function

This table function returns the minimum, maximum and average access times for all the segments in the tablespace.

Syntax

```
DBMS_HEAT_MAP.TABLESPACE_HEAT_MAP (
    tablespace_name      IN VARCHAR2)
  RETURN hm_tablespace_table PIPELINED;
```

Parameters

Table 86-10 *TABLESPACE_HEAT_MAP Procedure Parameters*

Parameter	Description
tablespace_name	Name of the tablespace

Return Values

Table 86-11 ***TABLESPACE_HEAT_MAP Procedure Return Values (Output Parameters)***

Parameter	Description
segment_count	Total number of segments in the tablespace
allocated_bytes	Space used by the segments in the tablespace
min_writetime	Oldest write time for the segment
max_writetime	Latest write time for the segment
avg_writetime	Average write time for the segment
min_readtime	Oldest read time for the segment
max_readtime	Latest read time for the segment
avg_writetime	Average write time for the segment
min_lookuptime	Oldest index lookup time for the segment
max_lookuptime	Latest index lookup time for the segment
avg_lookuptime	Average index lookup time for the segment
min_ftstime	Oldest full table scan time for the segment
max_ftstime	Latest full table scan time for the segment
avg_ftstime	Average full table scan time for the segment

87
DBMS_HIERARCHY

DBMS_HIERARCHY contains subprograms for validating the data in tables used by hierarchies and analytic views.

This chapter contains the following topics:

- DBMS_HIERARCHY Overview
- DBMS_HIERARCHY Security Model
- Summary of DBMS_HIERARCHY Subprograms

87.1 DBMS_HIERARCHY Overview

The DBMS_HIERARCHY package contains functions for validating that the contents of a database table are suitable for use by an analytic view or a hierarchy, a function for verifying the success of the validation, and a procedure for creating a table for logging validation operations.

> **Note:**
>
> Names specified by parameters of the DBMS_HIERARCHY subprograms are case-sensitive.

For information about using analytic views, see *Oracle Database Data Warehousing Guide*.

87.2 DBMS_HIERARCHY Security Model

Summarizes security considerations for the validation of analytic view and hierarchy objects.

All procedures in this package validate that the current user has the necessary privileges on the specified objects and return an error if those privileges are not found.

> **Note:**
>
> To ensure that the user has enough tablespace to log validation operations, do one of the following:
>
> - `GRANT UNLIMITED TABLESPACE TO` *username*`;`
> - `ALTER USERNAME` *username* `QUOTA` *size* `ON` *tablespace_name*`;`

The following system privileges are required to use this package:

To validate objects in the user's own schema:

- `CREATE TABLE` privilege for `CREATE_VALIDATE_LOG_TABLE` or to have `VALIDATE_ANALTYIC_VIEW` or `VALIDATE_HIERARCHY` automatically create a table
- `SELECT` privilege on the tables or views used by the analytic view or hierarchy
- `INSERT` privilege on the tables used by the attribute dimensions of the hierarchy or the fact table used by the analytic view

To validate objects in different schemas:

- `CREATE ANY TABLE` privilege for `CREATE_VALIDATE_LOG_TABLE` or to have the `VALIDATE_ANALTYIC_VIEW` or `VALIDATE_HIERARCHY` automatically create a table
- `INSERT ANY TABLE` privilege on the tables used by the attribute dimensions of the hierarchy or the fact table used by the analytic view

87.3 Summary of DBMS_HIERARCHY Subprograms

This table lists the `DBMS_HIERARCHY` subprograms and briefly describes them.

Subprogram	Description
CREATE_VALIDATE_LOG_TABLE Procedure	Creates a table that you can use for logging messages generated by the `VALIDATE_HIERARCHY` and `VALIDATE_ANALYTIC_VIEW` functions.
CREATE_VIEW_FOR_FACT_ROWS Procedure	This procedure creates a view for fact rows.
CREATE_VIEW_FOR_STAR_ROWS Procedure	This procedure creates a view for star rows.
GET_MV_SQL_FOR_AV_CACHE Function	This function either returns the SQL for a cache that is defined in the AV or the SQL for a given set of measures and levels. These measures and levels do not need to be part of a cache in the AV.
GET_MV_SQL_FOR_STAR_CACHE Function	This function returns the SQL in text form for the star cache.
UPGRADE_VALIDATE_LOG_TABLE Procedure	This procedure takes a log table and upgrades it to the newest format. Returns an error if the table cannot be upgraded due to other errors.
VALIDATE_ANALYTIC_VIEW Function	Validates that the data in a table is suitable for use by an analytic view.
VALIDATE_CHECK_SUCCESS Function	Indicates whether a prior call to `VALIDATE_HIERARCHY` or `VALIDATE_ANALYTIC_VIEW` was successful or produced validation errors.
VALIDATE_HIERARCHY Function	Validates that the data in a table is suitable for use by a hierarchy.

87.3.1 CREATE_VALIDATE_LOG_TABLE Procedure

This procedure creates a table that you can use for logging messages generated by the `VALIDATE_ANALYTIC_VIEW` or `VALIDATE_HIERARCHY` function, which validate data used by an analytic view or hierarchy.

The table that this procedure creates has the following structure.

```
NAME               NULL?    DATATYPE
------------------ -------- --------
LOG_NUMBER         NOT NULL NUMBER
ACTION_ORDER       NOT NULL NUMBER
OBJECT_OWNER       NOT NULL VARCHAR2(128 BYTE)
OBJECT_NAME        NOT NULL VARCHAR2(128 BYTE)
ACTION             NOT NULL VARCHAR2(10 BYTE)
TIME               NOT NULL TIMESTAMP(6)
ERROR_NUMBER                NUMBER
ERROR_MESSAGE               VARCHAR2(4000)
```

Syntax

```
DBMS_HIERARCHY.CREATE_VALIDATE_LOG_TABLE (
    table_name        IN  VARCHAR2,
    owner_name        IN  VARCHAR2         DEFAULT NULL
    IGNORE_IF_EXISTS  IN  PL/SQL BOOLEAN   DEFAULT FALSE);
```

Parameters

Parameter	Description
`table_name`	The name of the table to create.
`owner_name`	The name of the schema in which to create the table. If `owner_name` is `NULL`, then the table is created in the current user's schema.
`IGNORE_IF_EXISTS`	A Boolean that indicates whether to create the table if a table by the same name exists. If you specify a table, it must have the same structure as the table that this procedure creates.

Examples

Example 87-1 Creating a Validation Log Table

```
BEGIN
  DBMS_HIERARCHY.CREATE_VALIDATE_LOG_TABLE (
    'VAL_AV_HIERARCHY_LOG',
    'AV_USER',
    FALSE
  );
END;
/
```

87.3.2 CREATE_VIEW_FOR_FACT_ROWS Procedure

This procedure creates a view over the analytic view that exposes only the rows of the fact table. This allows standard SQL group functions to be used to aggregate those rows. The advantage to querying such a view rather than the fact table directly is that the analytic view may be able to perform query optimizations otherwise unavailable. When `include_meas` is `TRUE`, the `AV_AGGREGATE` group function may be used to expose measure columns defined in the analytic view.

Syntax

```
DBMS_HIERARCHY.CREATE_VIEW_FOR_FACT_ROWS (
      analytic_view_name         IN VARCHAR2,
      view__name                 IN VARCHAR2,
      dim_hier_seq               IN ID2_SEQUENCE  DEFAULT NULL,
      analytic_view_owner_name   IN VARCHAR2      DEFAULT
SYS_CONTEXT('USERENV', 'CURRENT_SCHEMA'),
      view_owner_name            IN VARCHAR2      DEFAULT
SYS_CONTEXT('USERENV', 'CURRENT_SCHEMA'),
      dim_qual_sep               IN VARCHAR2      DEFAULT '_',
      all_join_keys              IN BOOLEAN       DEFAULT TRUE,
      include_meas               IN BOOLEAN       DEFAULT FALSE,
      include_hier_attr          IN BOOLEAN       DEFAULT FALSE);
```

Parameters

Parameter	Description
`analytic_view_name`	The name of the analytic view to be created.
`view__name`	The name of the view.
`dim_hier_seq`	A sequence of `ID2` records. An `ID2` record contains two `VARCHAR2(128)` for the two parallel components, providing `(dim, hier)` name pairs. Default value is `NULL` which indicates that all hierarchies should be considered.
`analytic_view_owner_name`	The name of the analytic view owner. The default value is `SYS_CONTEXT('USERENV', 'CURRENT_SCHEMA')`.
`view_owner_name`	The owner of the view to be created. The default value is `SYS_CONTEXT('USERENV', 'CURRENT_SCHEMA')`.
`dim_qual_sep`	The separator to be used on the columns of the created view. For example, • for `fact` columns - `"FACT" || dim_qual_sep || {name of fact column alias}` • for `measures` - `"MEASURE" || dim_qual_sep || {measure name alias}` The default value is _.

Parameter	Description
all_join_keys	If TRUE, adds all of the join key columns in the AV to the view.
include_meas	If TRUE, include all of the base measures and calculated measures defined in the AV as columns in the created view.
include_hier_attr	If TRUE, include all of the hierarchical attributes defined in the AV as columns in the created view.

87.3.3 CREATE_VIEW_FOR_STAR_ROWS Procedure

This procedure creates a view over the analytic view that exposes only rows for a particular dimension star table. Such a view is intended to be used in conjunction with a corresponding fact rows view created using CREATE_VIEW_FOR_FACT_ROWS, joined using their corresponding keys as defined in the analytic view.

Syntax

```
DBMS_HIERARCHY.CREATE_VIEW_FOR_STAR_ROWS (
      analytic_view_name         IN VARCHAR2,
      dimension_alias            IN VARCHAR2,
      view__name                 IN VARCHAR2,
      analytic_view_owner_name   IN VARCHAR2      DEFAULT
SYS_CONTEXT('USERENV', 'CURRENT_SCHEMA'),
      view_owner_name            IN VARCHAR2      DEFAULT
SYS_CONTEXT('USERENV', 'CURRENT_SCHEMA'),
      hier_qual_sep              IN VARCHAR2      DEFAULT '_',
      include_hier_attr          IN BOOLEAN       DEFAULT FALSE);
```

Parameters

Parameter	Description
analytic_view_name	The name of the analytic view to be created.
dimension_alias	The alias of the attribute dimension that you wish to create a star rows view for.
view__name	The name of the view.
analytic_view_owner_name	The name of the analytic view owner. The default value is SYS_CONTEXT('USERENV', 'CURRENT_SCHEMA').
view_owner_name	The owner of the view to be created. The default value is SYS_CONTEXT('USERENV', 'CURRENT_SCHEMA').
hier_qual_sep	The separator to be used. The separator is between the attribute dimension name and the built-in hierarchical attributes, such as MEMBER_NAME, LEVEL_NAME, DEPTH, and so on. The default value is _.
include_hier_attr	If TRUE, include all of the hierarchical attributes defined in the AV as columns in the created view.

87.3.4 GET_MV_SQL_FOR_AV_CACHE Function

This function has two signatures. The first version of this method returns the SQL for a cache that is defined in the AV. The second version of this method returns SQL for a given set of measures and levels. These measures and levels do not need to be part of a cache in the AV.

Syntax

```
DBMS_HIERARCHY.GET_MV_SQL_FOR_AV_CACHE (
    analytic_view_name         IN
VARCHAR2,
    cache_idx                  IN    NUMBER,
    analytic_view_owner_name   IN    VARCHAR2  DEFAULT
SYS_CONTEXT('USERENV', 'CURRENT_SCHEMA'))
  RETURN CLOB;

DBMS_HIERARCHY.GET_MV_SQL_FOR_AV_CACHE (
    analytic_view_name         IN
VARCHAR2,
    lvl_seq                    IN    ID3_SEQUENCE  DEFAULT NULL,
    meas_seq                   IN    ID_SEQUENCE   DEFAULT NULL,
    analytic_view_owner_name   IN    VARCHAR2  DEFAULT
SYS_CONTEXT('USERENV', 'CURRENT_SCHEMA'))
  RETURN CLOB;
```

Parameters

Table 87-1 GET_MV_SQL_FOR_AV_CACHE Function Parameters

Parameter	Description
analytic_view_name	The name of the analytic view to be created.
cache_idx	Zero-based index for the caches defined on the AV.
analytic_view_owner_name	The name of the analytic view owner. The default value is SYS_CONTEXT('USERENV', 'CURRENT_SCHEMA').
lvl_seq	The list of levels that the cache should be based on.
meas_seq	The list of measures that the cache should be based on.

87.3.5 GET_MV_SQL_FOR_STAR_CACHE Function

This function returns the SQL in text form for the star cache.

Syntax

```
DBMS_HIERARCHY.GET_MV_SQL_FOR_STAR_CACHE (
    attr_dim_name            IN  VARCHAR2,
    attr_dim_owner_name      IN  VARCHAR2 DEFAULT SYS_CONTEXT('USERENV',
'CURRENT_SCHEMA'))
  RETURN CLOB;
```

Parameters

Table 87-2 GET_MV_SQL_FOR_STAR_CACHE Function Parameters

Parameter	Description
attr_dim_name	The name of the attribute dimension on which to create a cache.
attr_dim_owner_name	The schema that owns the attribute dimension. The default value is SYS_CONTEXT('USERENV', 'CURRENT_SCHEMA').

87.3.6 UPGRADE_VALIDATE_LOG_TABLE Procedure

This procedure takes a log table and upgrades it to the newest format. Returns an error if the table cannot be upgraded due to other errors.

Syntax

```
DBMS_HIERARCHY.UPGRADE_VALIDATE_LOG_TABLE (
    table_name        IN  VARCHAR2,
    owner_name        IN  VARCHAR2         DEFAULT NULL);
```

Parameters

Parameter	Description
table_name	The name of the table to upgrade.
owner_name	The name of the schema in which to find the table. If owner_name is NULL, then the table is created in the current user's schema.

87.3.7 VALIDATE_ANALYTIC_VIEW Function

This function validates that the data in a table or view conforms to the logical constraints inherent in the definition of an analytic view.

Syntax

```
DBMS_HIERARCHY.VALIDATE_ANALYTIC_VIEW (
      analytic_view_name         IN VARCHAR2   DEFAULT NULL,
      analytic_view_owner_name   IN VARCHAR2   DEFAULT NULL,
      log_table_name             IN VARCHAR2   DEFAULT NULL,
      log_table_owner_name       IN VARCHAR2   DEFAULT NULL)
      RETURN NUMBER;
```

Parameters

Parameter	Description
analytic_view_name	The name of the analytic view to validate.
analytic_view_owner_name	The name of the owner of the schema that contains the analytic view.

Parameter	Description
log_table_name	The name of the validation log table in which to put the results of the validation operation.
log_table_owner_name	The name of the owner of the schema in which the validation log table exists or in which to create the table.

Returns

The number of the entry in the validation log table for the validation results.

Usage Notes

If the log_table_name parameter is NULL, then the VALIDATE_ANALYTIC_VIEW function creates a validation log table. The name of the table it creates is DBMS_HIERARCHY_LOG.

When the validation operation begins, a row is inserted into the log table with the action of START. When the operation completes, a row is inserted into the log table with the action of END. When an error is detected, a row is inserted into the log table with the action of ERROR, and the associated error_number and error_message columns are populated. All rows inserted into the validation log table include a log number and the time of the insert.

The VALIDATE_ANALYTIC_VIEW function verifies that the following conditions are true for each attribute dimension the analytic view is dimensioned by:

- The key values found in the fact table for the attribute dimension must exist in the star schema dimension table for that attribute dimension.
- The referenced attribute values for the attribute dimension must be unique across all rows of the star schema dimension table for that dimension.

Also, for every hierarchy in the analytic view, the function verifies that the following conditions are true:

- The primary key of a level determines a unique value for each attribute of the level.
- For each row of the table or view used by the attribute dimension of the hierarchy, the value for every level key column (including alternate keys) of a NOT NULL level is non-NULL.
- For each row of the table or view, either all level key columns and alternate key columns of a SKIP WHEN NULL level must be NULL or they must all be non-NULL. This verifies that the alternate level key is determined by the level key.
- For each group of rows that have the same alternate key column values for a level, the key column values must have the same column values. This verifies that the level key is determined by the alternate level key, which is required for an alternate key.

Examples

Example 87-2 Validating an Analytic View

```
DECLARE
  log_num NUMBER;
```

```
  obj_name VARCHAR2(8) := 'SALES_AV';
BEGIN
   log_num := DBMS_HIERARCHY.VALIDATE_ANALYTIC_VIEW(obj_name);
END;
/
```

87.3.8 VALIDATE_CHECK_SUCCESS Function

This function indicates whether a prior call to `VALIDATE_HIERARCHY` or `VALIDATE_ANALYTIC_VIEW` was successful or produced validation errors.

Syntax

```
DBMS_HIERARCHY.VALIDATE_CHECK_SUCCESS (
    TOPOBJ_NAME           IN  VARCHAR2,
    TOPOBJ_OWNER          IN  VARCHAR2,
    LOG_NUMBER            IN  VARCHAR2
    LOG_TABLE_NAME        IN  VARCHAR2
    LOG_TABLE_OWNER_NAME  IN  VARCHAR2 )
    RETURN VARCHAR2;
```

Parameters

Parameter	Description
`TOPOBJ_NAME`	The name of the hierarchy or analytic view.
`TOPOBJ_OWNDER`	The owner of the hierarchy or analytic view.
`LOG_NUMBER`	The number of the log entry.
`LOG_TABLE_NAME`	The name of the log table.
`LOG_TABLE_OWNER_NAME`	The name of the schema in which the table exits.

Returns

A `VARCHAR2` that is SUCCESS if no errors occurred or ERROR if errors did occur.

Examples

Example 87-3 Using VALIDATE_CHECK_SUCCESS

This example finds out whether the prior call to `VALIDATE_ANALTYIC_VIEW` encountered errors.

```
DECLARE
  log_num NUMBER;
  succ VARCHAR2(7);
  obj_name VARCHAR2(8) := 'SALES_AV';
BEGIN
   log_num := dbms_hierarchy.validate_analytic_view(obj_name);
   succ := dbms_hierarchy.validate_check_success(
      topobj_name => obj_name, log_number => log_num);
  IF (succ != 'SUCCESS') THEN
     RAISE_APPLICATION_ERROR(
       num => -20000,
       msg => 'Validate failed!');
```

```
  END IF;
END;
/
```

87.3.9 VALIDATE_HIERARCHY Function

This function validates that the data in a table or view conforms to the logical constraints inherent in the definitions of an attribute dimension that uses the table or view and a hierarchy that uses the attribute dimension.

Syntax

```
DBMS_HIERARCHY.VALIDATE_HIERARCHY (
      hier_name                IN VARCHAR2,
      hier_owner_name          IN VARCHAR2    DEFAULT NULL,
      log_table_name           IN VARCHAR2    DEFAULT NULL,
      log_table_owner_name     IN VARCHAR2    DEFAULT NULL)
      RETURN NUMBER;
```

Parameters

Parameter	Description
`hier_name`	The name of the hierarchy to validate.
`hier_owner_name`	The name of the owner of the schema that contains the hierarchy.
`log_table_name`	The name of the validation log table in which to put the results of the validation operation.
`log_table_owner_name`	The name of the owner of the schema in which the validation log table exists or in which to create the table.

Returns

The number of the entry in the validation log table for the validation results.

Usage Notes

If the `log_table_name` parameter is `NULL`, then the `VALIDATE_HIERARCHY` function creates a validation log table. The name of the table it creates is DBMS_HIERARCHY_LOG.

When the validation operation begins, a row is inserted into the log table with the action of `START`. When the operation completes, a row is inserted into the log table with the action of `END`. When an error is detected, a row is inserted into the log table with the action of `ERROR`, and the associated `error_number` and `error_message` columns are populated. All rows inserted into the validation log table include a log number and the time of the insert.

The `VALIDATE_HIERARCHY` function verifies that the following conditions are true for the hierarchy:

- The primary key of a level determines a unique value for each attribute of the level.

- For each row of the table or view used by the attribute dimension of the hierarchy, the value for every level key column (including alternate keys) of a NOT NULL level is non-NULL.
- For each row of the table or view, either all level key columns and alternate key columns of a SKIP WHEN NULL level must be NULL or they must all be non-NULL. This verifies that the alternate level key is determined by the level key.
- For each group of rows that have the same alternate key column values for a level, the key column values must have the same column values. This verifies that the level key is determined by the alternate level key, which is required for an alternate key.

Examples

Example 87-4 Validating a Hierarchy and Specifying a Table Name

This example validates the PRODUCT_HIER hierarchy and specifies that the results be inserted in the table named VAL_AV_HIERARCHY_LOG. The owner of the hierarchy and of the schema that contains the table is AV_USER.

```
-- Create a log table.
BEGIN
  DBMS_HIERARCHY.CREATE_VALIDATE_LOG_TABLE (
    'VAL_AV_HIERARCHY_LOG',
    'AV_USER',
    FALSE
  );
END;
/
-- Validate the hierarchy.
DECLARE
  log_num NUMBER;
  obj_name VARCHAR2(12) := 'PRODUCT_HIER';
  table_name  VARCHAR2(28) := 'VAL_AV_HIERARCHY_LOG';
BEGIN
   log_num := DBMS_HIERARCHY.VALIDATE_HIERARCHY(obj_name, 'AV_USER',
table_name);
END;
/
```

Query the log table.

```
SELECT LOG_NUMBER, ACTION, OBJECT_NAME, ERROR_NUMBER, ERROR_MESSAGE
  FROM AV_USER.VAL_AV_HIERARCHY_LOG;
  WHERE OBJECT_NAME = 'PRODUCT_HIER';

LOG_NUMBER ACTION     OBJECT_NAME         ERROR_NUMBER ERROR_MESSAGE
---------- ---------- ------------------- ------------ -------------
         1 START      PRODUCT_HIER
         1 END        PRODUCT_HIER
```

Example 87-5 Validating a Hierarchy Without Specifying a Table Name

This example shows that if you do not specify a validation log table, then the `VALIDATE_HIERARCHY` function creates one named DBMS_HIERARCHY_LOG.

```
DECLARE
  log_num NUMBER;
  obj_name VARCHAR2(12) := 'PRODUCT_HIER';
BEGIN
   log_num := DBMS_HIERARCHY.VALIDATE_HIERARCHY(obj_name);
END;
```

Query the log table.

```
SELECT LOG_NUMBER, ACTION, OBJECT_NAME, ERROR_NUMBER, ERROR_MESSAGE
  FROM DBMS_HIERARCHY_LOG
  WHERE OBJECT_NAME = 'PRODUCT_HIER';

LOG_NUMBER ACTION     OBJECT_NAME         ERROR_NUMBER ERROR_MESSAGE
---------- ---------- ------------------- ------------ -------------
         1 START      PRODUCT_HIER
         1 END        PRODUCT_HIER
```

88
DBMS_HM

This package contains constants and procedure declarations for health check management. Health Monitor provides facilities to run a check store and retrieve the reports through `DBMS_HM` package

This chapter contains the following topics:

- Security Model
- Summary of DBMS_HM Subprograms

> **See Also:**
>
> *Oracle Database Administrator's Guide* for more information about "Health Monitor"

88.1 DBMS_HM Security Model

Users must have `EXECUTE` privilege to run the procedures of `DBMS_HM` package.

88.2 Summary of DBMS_HM Subprograms

This table lists the `DBMS_CONNECTION_POOL` subprograms and briefly describes them.

Table 88-1 DBMS_HM Package Subprograms

Subprogram	Description
GET_RUN_REPORT Function	Returns the report for the specified checker run
RUN_CHECK Procedure	Runs the specified checker with the given arguments

88.2.1 GET_RUN_REPORT Function

This function returns the report for the specified checker run.

Syntax

```
DBMS_HM.GET_RUN_REPORT (
    run_name      IN  VARCHAR2,
    type           IN  VARCHAR2 := 'TEXT',
    level          IN  VARCHAR2 := 'BASIC',)
  RETURN CLOB;
```

Parameters

Table 88-2 GET_RUN_REPORT Function Parameters

Parameter	Description
run_name	Name of the check's run
type	Report format type. Possible values are 'HTML', 'XML' and 'TEXT'. Default report type is 'TEXT'.
level	Details of report, possible value are 'BASIC' and 'DETAIL'. Caution: Currently only 'BASIC' level is supported.

88.2.2 RUN_CHECK Procedure

This procedure runs the specified checker with the specified arguments.

You can specify a name for the run, the inputs needed and maximum time-out for the run. The run report will be maintained persistently in the database.

Syntax

```
DBMS_HM.RUN_CHECK (
   check_name     IN  VARCHAR2,
   run_name       IN  VARCHAR2 := NULL,
   timeout        IN  NUMBER := NULL,
   input_params   IN  VARCHAR2 := NULL);
```

Parameters

Table 88-3 RUN_CHECK Procedure Parameters

Parameter	Description
check_name	Name of the check to be invoked. Check names and their parameters can be accessed from the V$HM_CHECK and V$HM_CHECK_PARAM views. Users can run all checks which are not internal in nature: SELECT name FROM V$HM_CHECK WHERE INTERNAL_CHECK = 'N' retrieves the list of checks that can be run manually by users.
run_name	Name with which external users can uniquely identify this check's run. If NULL value is passed, then HM creates a unique name and associates with this check's run.
timeout	Maximum amount of time (in units of seconds), this checker run is allowed to run. HM will interrupt the run, if it the specified time elapses for the run. If NULL value is passed, HM doesn't impose any timeout limits on the run.

Table 88-3 (Cont.) RUN_CHECK Procedure Parameters

Parameter	Description

input_params	Input string: which consists of name, value pairs de-limited by a special character ';'.
	Example ('Data Block Integrity Check' invocation may take following type of input parameters.
	`'BLC_DF_NUM=1;BLC_BL_NUM=23456'`
	Input parameters BLC_DF_NUM and BLC_BL_NUM have values '1' and '23456' respectively.
	Every check will have well defined set of inputs associated with it. These Input parameters, their types, default values and descriptions can be obtained using V$HM_CHECK_PARAM view.
	Example: The following query gets the list of parameters, their default values and descriptions for a 'Data Block Integrity Check'
	`SELECT a.* FROM v$hm_check_param a, v$hm_check b WHERE a.check_id = b.id AND b.name = 'Data Block Integrity Check';`

89
DBMS_HPROF

The DBMS_HPROF package provides an interface for profiling the execution of PL/SQL applications. It provides services for collecting the hierarchical profiler data, analyzing the raw profiler output and profiling information generation.

This chapter contains the following topic:

- Summary of DBMS_HPROF Subprograms

> **See Also:**
>
> *Oracle Database Development Guide* for more information about the "PL/SQL Hierarchical Profiler"

89.1 Summary of DBMS_HPROF Subprograms

This table lists and briefly describes the DBMS_HPROF package subprograms.

Table 89-1 DBMS_HPROF Package Subprograms

Subprogram	Description
ANALYZE Function	Analyzes the raw profiler output and produces hierarchical profiler information in database tables.
CREATE_TABLES Procedure	Creates the hierarchical profiler database tables and data structures in the user's session.
START_PROFILING Procedure	Starts hierarchical profiler data collection in the user's session.
STOP_PROFILING Procedure	Stops profiler data collection in the user's session.

89.1.1 ANALYZE Function

This function analyzes the raw profiler output and produces hierarchical profiler information in database tables or generates out-of-the-box HTML reports.

Syntax

```
DBMS_HPROF.ANALYZE (
   trace_id         IN NUMBER,
   summary_mode     IN BOOLEAN DEFAULT FALSE,
   trace            IN VARCHAR2 DEFAULT NULL,
   skip             IN PLS_INTEGER DEFAULT 0,
   collect          IN PLS_INTEGER DEFAULT NULL,
   run_comment      IN VARCHAR2 DEFAULT NULL)
  RETURN NUMBER;
```

```
DBMS_HPROF.ANALYZE (
   trace_id         IN NUMBER,
   report_clob      OUT CLOB,
   trace            IN VARCHAR2 DEFAULT NULL,
   skip             IN PLS_INTEGER DEFAULT 0,
   collect          IN PLS_INTEGER DEFAULT NULL);
```

Parameters

Table 89-2 ANALYZE Function Parameters

Parameter	Description
`trace_id`	The `trace_id` of the raw profiler data entry in the raw profiler data table (`dbmshp_trace_data`).
`summary_mode`	By default (that is, when `summary_mode` is FALSE), a detailed analysis is done. When `summary_mode` is `TRUE`, only top-level summary information is generated into the database table.
`report_clob`	The analyzed HTML report.
`trace`	Analyzes only the subtrees rooted at the specified trace entry. By default (when trace is `NULL`), the analysis/reporting is generated for the entire run. The trace entry must be specified in a special quoted qualified format. For example, '"HR"."PKG"."FOO"' or '""."".".__plsql_vm"'. If multiple overloads exist for the specified name, all of them will be analyzed.
`skip`	Used only when `trace` is specified. Analyze only the subtrees rooted at the specified trace, but ignore the first `skip` invocations to trace. The default value for skip is `0`.
`collect`	Used only when `trace` is specified. Analyze `collect` number of invocations of traces (starting from `skip+1`'th invocation). By default, only 1 invocation is collected.
`run_comment`	User-provided comment for this run.

Return Values

A unique run identifier for this run of the analyzer. This can then be used to look up the results corresponding to this run from the hierarchical profiler tables.

Usage Notes

- Use the `DBMS_HPROF.CREATE_TABLES` subprogram to create the hierarchical profiler database tables and other data structures required for persistently storing the results of analyzing the raw profiler data.
- Calling the `DBMS_HPROF.CREATE_TABLES` with default value (`FALSE`) will raise error if table already exists.
- Use `DBMS_HPROF.CREATE_TABLES(TRUE)` to drop any previously created hierarchical profiler tables.

- Use the DBMS_HPROF.CREATE_TABLES to drop any previously created hierarchical profiler tables. By default, force_it is FALSE; therefore, to drop any previously created hierarchical profiler tables you must set the value of force_it to TRUE.
- If trace_id entry is NULL, error is raised.
- If trace_id entry in the raw profiler data table does not exist, error is raised.
- If raw data of the trace_id entry in the raw profiler data table is NULL or is zero size, error is raised.

Examples

The following snippet installs the hierarchical profiler tables in HR schema.

```
connect HR/HR;
```

The following example analyzes and generates HTML CLOB report from a raw profiler data table.

```
DECLARE
        reportclob clob;
        trace_id number;
BEGIN
    -- create raw profiler data and analysis tables
    -- force_it =>TRUE will dropped the tables if table exists
    DBMS_HPROF.CREATE_TABLES(force_it =>TRUE);

    -- Start profiling
    -- Write raw profiler data in raw profiler data table
    trace_id := DBMS_HPROF.START_PROFILING;

    -- Run procedure to be profiled
    test;

    -- Stop profiling
    DBMS_HPROF.STOP_PROFILING;

    -- analyzes trace_id entry in raw profiler data table and produce
    -- analyzed HTML report in reportclob
    DBMS_HPROF.ANALYZE(trace_id , reportclob);
END;
/
```

89.1.2 CREATE_TABLES Procedure

Creates the hierarchical profiler database tables and data structures in the user's session.

Syntax

```
DBMS_HPROF.CREATE_TABLES (
   force_it         IN BOOLEAN DEFAULT FALSE);
```

Parameters

Table 89-3 CREATE_TABLES Procedure Parameters

Parameter	Description
force_it	If FALSE and DBMS_HPROF tables are present, then an HPROF error is raised. If TRUE, then the procedure creates tables. If the tables already exist, then they are dropped and new tables are created.

> **Note:**
>
> Users need not use the dbmshptab.sql script located in the rdbms/admin directory to create the hierarchical profiler database tables and data structures anymore.
>
> The dbmshptab.sql script is deprecated starting in Oracle Database 18*c*.

89.1.3 START_PROFILING Procedure

This procedure starts hierarchical profiler data collection in the user's session.

Syntax

```
DBMS_HPROF.START_PROFILING(
   max_depth     IN PLS_INTEGER DEFAULT NULL,
   sqlmonitor    IN BOOLEAN DEFAULT TRUE,
   run_comment   IN VARCHAR2 DEFAULT NULL)
RETURN NUMBER;
```

Parameters

Table 89-4 START_PROFILING Procedure Parameters

Parameter	Description
max_depth	By default (that is, when max_depth value is NULL) profile information is gathered for all functions irrespective of their call depth. When a non-NULL value is specified for max_depth, the profiler collects data only for functions up to a call depth level of max_depth.
sqlmonitor	Generates a real-time monitoring report for a profiler run when the profiler run ends. The default value is TRUE.
run_comment	User provided comment for the profiler data collection run.

Return Values

Unique run identifier for this profiler run. This can then be used to look up the results corresponding to this run from the hierarchical profiler tables.

Usage Notes

- Even though the profiler does not individually track functions at depth greater than `max_depth`, the time spent in such functions is charged to the ancestor function at depth `max_depth`.
- Raw profiler data is generated in the raw profiler data table with an unique `trace_id`.
- The unique `trace_id` is used to manage the raw profiler output stored in the raw profiler data table.

89.1.4 STOP_PROFILING Procedure

This procedure stops profiler data collection in the user's session. This subprogram also has the side effect of flushing data collected so far in the session, and it signals the end of a run. When the `STOP_PROFILING` procedure returns CLOB, it contains the Real-Time Monitoring report for the profiler run.

Syntax

```
DBMS_HPROF.STOP_PROFILING;

DBMS_HPROF.STOP_PROFILING
  RETURN CLOB;
```

Examples

Profiling with raw profiler data table

```
DECLARE
    analyze_runid number;
    trace_id number;
BEGIN
    -- create raw profiler data and analysis tables
    -- call create_tables with force_it =>FALSE (default) when
    -- raw profiler data and analysis tables do not exist already
    DBMS_HPROF.CREATE_TABLES;
    -- Start profiling
    -- Write raw profiler data in raw profiler data table
    trace_id := DBMS_HPROF.START_PROFILING;
    -- Run the procedure to be profiled
    test;
    -- Stop profiling
    DBMS_HPROF.STOP_PROFILING;
    -- analyzes trace_id entry in raw profiler data table and writes
    -- hierarchical profiler information in hprof's analysis tables
    analyze_runid := DBMS_HPROF.ANALYZE(trace_id);
END;
/
```

90
DBMS_HS_PARALLEL

The DBMS_HS_PARALLEL PL/SQL package enables parallel processing for heterogeneous targets access. This package is designed to improve performance when retrieving data from a large foreign table.

This chapter discusses the following topics:

- Using DBMS_HS_PARALLEL
- Summary of DBMS_HS_PARALLEL Subprograms

90.1 Using the DBMS_HS_PARALLEL Subprogram

DBMS_HS_PARALLEL is compiled with the authorization ID of CURRENT_USER, which uses invoker's rights. In other words, all procedures in this package are executed with the privileges of the calling user.

90.2 Summary of DBMS_HS_PARALLEL Subprograms

This table lists the DBMS_HS_PARALLEL subprograms in alphabetic order and briefly describes them.

Table 90-1 DBMS_HS_PARALLEL Package Subprograms

Subprogram	Description
CREATE_OR_REPLACE_VIEW	Creates (or replaces) a read-only view to be referenced for retrieving the data from a remote table in parallel.
CREATE_TABLE_TEMPLATE	Writes out a CREATE TABLE template based on information gathered from the remote table. You can use the information to add any optimal Oracle CREATE TABLE clauses.
DROP_VIEW	Drops the view and internal objects created by the CREATE_OR_REPLACE_VIEW procedure. If the view has not already been created by the CREATE_OR_REPLACE_VIEW procedure, an error message is returned.
LOAD_TABLE	Loads the data from a remote table to a local Oracle table in parallel. If the local Oracle table does not already exist, it is created automatically.

90.2.1 CREATE_OR_REPLACE_VIEW Procedure

This procedure creates (or replaces) a read-only view to be referenced for retrieving the data from a remote table in parallel.

Syntax

```
CREATE_OR_REPLACE_VIEW (remote_table, database_link, oracle_view, parallel_degree)
```

Parameters

Table 90-2 CREATE_OR_REPLACE_VIEW Procedure Parameters

Parameters	Description
remote_table	The name of the remote database table. It is specified as [remote_schema_name.]remote_table_name.
database_link	The remote database link name. The call can only be applied to a heterogeneous services database link.
oracle_view	The name of the Oracle view. It is specified as [schema_name.]oracle_view_name. The default schema name is the current user. If the oracle_view parameter is not specified, the remote table name will be used as the view name.
parallel_degree	The number of parallel processes for the operation is computed based on the range-partition number if applicable, or the number of CPUs. The range of values is 2 to 16.

Usage Notes

- The specified Oracle view is created and future reference of this view utilizes internal database objects for parallel retrieval of remote non-Oracle table data. If the Oracle view already exists, the following Oracle error message is raised:

  ```
  ORA-00955: name is already used by an existing object
  ```

- This view is created as a read-only view. If you attempt to insert and update the view, the following Oracle error message is raised:

  ```
  ORA-01733: virtual column not allowed here
  ```

- If the remote table or the database link does not exist, one of the following Oracle error messages is raised:

  ```
  ORA-00942: table or view does not exist
  or
  ORA-02019: connection description for remote database not found
  ```

- You need the CREATE VIEW, CREATE TABLE, CREATE TYPE, CREATE PACKAGE, and CREATE FUNCTION privileges to execute the CREATE_OR_REPLACE_VIEW procedure.
- If you encounter either of the following Oracle error messages, increase the PROCESSES and SESSIONS parameter in the Oracle initialization parameter file:

  ```
  ORA-12801: error signaled in parallel query server P003
  or
  ORA-00018: maximum number of session exceeded
  ```

- Because the CREATE_OR_REPLACE_VIEW procedure creates some internal objects, use the DROP_VIEW procedure to drop the view and the internal objects. The SQL DROP VIEW statement only drops the view and not the internal objects.

90.2.2 CREATE_TABLE_TEMPLATE Procedure

This procedure writes out a `CREATE TABLE` template based on information gathered from the remote table. You can use the information to add any optimal Oracle `CREATE TABLE` clauses.

Syntax

```
CREATE_TABLE_TEMPLATE (remote_table, database_link, oracle_table,
create_table_template_string)
```

Parameters

Table 90-3 CREATE_TABLE_TEMPLATE Procedure Parameters

Parameter	Description
`remote_table`	The name of the remote database table. It is specified as `[remote_schema_name.]remote_table_name`.
`database_link`	The remote database link name. The call can only be applied to a heterogeneous services database link.
`oracle_table`	The name of the local Oracle table the data will be loaded into. It is specified as `[schema_name.]oracle_table_name`. The default schema name is the current user. If the `oracle_table` parameter is not specified, the remote table name will be used as the local Oracle name.
`create_table_template_string`	Contains the Oracle `CREATE TABLE` SQL template when the procedure is returned.

90.2.3 DROP_VIEW Procedure

This procedure drops the view and internal objects created by the `CREATE_OR_REPLACE_VIEW` procedure. If the view has not already been created by the `CREATE_OR_REPLACE_VIEW` procedure, an error message is returned.

Syntax

```
DROP_VIEW (oracle_view)
```

Parameters

Table 90-4 DROP_VIEW Procedure Parameter

Parameter	Description
`oracle_view`	The name of the Oracle view created by the `CREATE_OR_REPLACE_VIEW` procedure. If the view has not been created by the `CREATE_OR_REPLACE_VIEW` procedure, an error is returned.

90.2.4 LOAD_TABLE Procedure

This procedure loads the data from a remote table to a local Oracle table in parallel. If the local Oracle table does not already exist, it is created automatically.

Syntax

```
LOAD_TABLE (remote_table, database_link, oracle_table, truncate,
parallel_degree, row_count)
```

Parameters

Table 90-5 LOAD_TABLE Procedure Parameters

Parameter	Description
`remote_table`	The name of the remote database table. It is specified as `[remote_schema_name.]remote_table_name`
`database_link`	The remote database link name. The call can only be applied to a heterogeneous services database link.
`oracle_table`	The name of the local Oracle table the data will be loaded into. It is specified as `[schema_name.]oracle_table_name`. The default schema name is the current user. If the `oracle_table` parameter is not specified, the remote table name will be used as the local Oracle name.
`truncate`	Determines whether the Oracle table is truncated before the data is loaded. The value is either TRUE or FALSE. The default value is TRUE which means the Oracle table is truncated first. When set to FALSE, the Oracle table will not be truncated before the data is loaded.
`parallel_degree`	The number of parallel processes for the operation is computed based on the range-partition number if applicable, or the number of CPUs. The range of values is 2 to 16.
`row_count`	Contains the number of rows just added with the load table operation.

Usage Notes

- This procedure only loads the remote table data into Oracle local table. It does not create a key, index, constraints or any other dependencies such as triggers. It is recommended that you create these dependencies after the table data is loaded as performance will improve greatly. You will need to decide whether to create the dependencies before or after the data is loaded based on your knowledge of the remote table data and dependencies.
- If the local table does not exist, the `LOAD_TABLE` procedure creates a simple (non-partitioned) local table based on the exact column matching of the remote table after which the data is inserted into the local table.

- If the remote table or the database link does not exist, an error message is returned.
- If the local table is incompatible with the remote table, an error message is returned.
- You need the `CREATE TABLE`, `CREATE TYPE`, `CREATE PACKAGE`, and `CREATE FUNCTION` privileges to execute the `LOAD_TABLE` procedure.
- If you encounter either of the following Oracle error messages, increase the `PROCESSES` and `SESSIONS` parameter in Oracle initialization parameter file:

  ```
  ORA-12801: error signaled in parallel query server P003
  or
  ORA-00018: maximum number of session exceeded
  ```

- One of the following is required for parallel processing:
  - The remote table is range partitioned.
  - Histogram information for a numeric column is available.
  - There is a numeric index or primary key.
- To drop the local table, use the `DROP TABLE` SQL statement.

91
DBMS_HS_PASSTHROUGH

The DBMS_HS_PASSTHROUGH PL/SQL package allows you to send a statement directly to a non-Oracle system without being interpreted by the Oracle server. This can be useful if the non-Oracle system allows operations in statements for which there is no equivalent in Oracle.

This chapter discusses the following topics:

- DBMS_HS_PASSTHROUGH Overview
- DBMS_HS_PASSTHROUGH Operational Notes
- Summary of DBMS_HS_PASSTHROUGH Subprograms

> **See Also:**
>
> *Oracle Database Heterogeneous Connectivity User's Guide* for more information about this package

91.1 DBMS_HS_PASSTHROUGH Overview

You can execute passthrough SQL statements directly at the non-Oracle system using the PL/SQL package DBMS_HS_PASSTHROUGH. Any statement executed with this package is executed in the same transaction as standard SQL statements.

> **See Also:**
>
> *Oracle Database Heterogeneous Connectivity User's Guide* for information about this package

91.2 DBMS_HS_PASSTHROUGH Operational Notes

The DBMS_HS_PASSTHROUGH package is a virtual package. It conceptually resides at the non-Oracle system. In reality, however, calls to this package are intercepted by Heterogeneous Services and mapped to one or more Heterogeneous Services calls. The driver, in turn, maps these Heterogeneous Services calls to the API of the non-Oracle system. The client application should invoke the procedures in the package through a database link in exactly the same way as it would invoke a non-Oracle system stored procedure. The special processing done by Heterogeneous Services is transparent to the user.

91.3 Summary of DBMS_HS_PASSTHROUGH Subprograms

This table lists the DBMS_HS_PASSTHROUGH subprograms and briefly describes them.

Table 91-1 ***DBMS_HS_PASSTHROUGH Package Subprograms***

Subprogram	Description
BIND_INOUT_VARIABLE Procedure	Binds IN OUT bind variables
BIND_INOUT_VARIABLE_RAW Procedure	Binds IN OUT bind variables of datatype RAW
BIND_OUT_VARIABLE Procedure	Binds an OUT variable with a PL/SQL program variable
BIND_OUT_VARIABLE_RAW Procedure	Binds an OUT variable of datatype RAW with a PL/SQL program variable
BIND_VARIABLE Procedure	Binds an IN variable positionally with a PL/SQL program variable
BIND_VARIABLE_RAW Procedure	Binds IN variables of type RAW
CLOSE_CURSOR Procedure	Closes the cursor and releases associated memory after the SQL statement has been run at the non-Oracle system
EXECUTE_IMMEDIATE Procedure	Runs a (non-SELECT) SQL statement immediately, without bind variables
EXECUTE_NON_QUERY Function	Runs a (non-SELECT) SQL statement
FETCH_ROW Function	Fetches rows from a query
GET_VALUE Procedure	Retrieves column value from SELECT statement, or retrieves OUT bind parameters
GET_VALUE_RAW Procedure	Similar to GET_VALUE, but for datatype RAW
OPEN_CURSOR Function	Opens a cursor for running a passthrough SQL statement at the non-Oracle system
PARSE Procedure	Parses SQL statement at non-Oracle system

91.3.1 BIND_INOUT_VARIABLE Procedure

This procedure binds IN OUT bind variables.

Syntax

```
DBMS_HS_PASSTHROUGH.BIND_OUT_VARIABLE (
   c      IN  BINARY_INTEGER NOT NULL,
   p      IN  BINARY_INTEGER NULL,
   v      OUT <dty>,
   n      IN  VARCHAR2);
```

<dty> is either DATE, NUMBER, or VARCHAR2.

> **See Also:**
>
> For binding OUT variables of datatype RAW, see BIND_OUT_VARIABLE_RAW Procedure.

Pragmas

```
Purity level defined : WNDS, RNDS
```

Parameters

Table 91-2 BIND_INOUT_VARIABLE Procedure Parameters

Parameter	Description
c	Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines OPEN_CURSOR and PARSE respectively.
p	Position of the bind variable in the SQL statement: Starts at 1.
v	This value is used for two purposes: - To provide the IN value before the SQL statement is run. - To determine the size of the out value.
n	(Optional) Name of the bind variable. For example, in `SELECT * FROM emp WHERE ename=:ename`, the position of the bind variable :ename is 1, the name is :ename. This parameter can be used if the non-Oracle system supports "named binds" instead of positional binds. Passing the position is still required.

Exceptions

Table 91-3 BIND_INOUT_VARIABLE Procedure Exceptions

Exception	Description
ORA-28550	The cursor passed is invalid.
ORA-28552	Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?)
ORA-28553	The position of the bind variable is out of range.
ORA-28555	A NULL value was passed for a NOT NULL parameter.

91.3.2 BIND_INOUT_VARIABLE_RAW Procedure

This procedure binds IN OUT bind variables of datatype RAW.

Syntax

```
DBMS_HS_PASSTHROUGH.BIND_INOUT_VARIABLE_RAW (
   c      IN     BINARY_INTEGER NOT NULL,
   p      IN     BINARY_INTEGER NOT NULL,
   v      IN OUT RAW,
   n      IN     VARCHAR2);
```

Pragmas

```
Purity level defined : WNDS, RNDS
```

Parameters

Table 91-4 BIND_INOUT_VARIABLE_RAW Procedure Parameters

Parameter	Description
c	Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed using the routines OPEN_CURSOR and PARSE respectively.
p	Position of the bind variable in the SQL statement: Starts at 1.
v	This value is used for two purposes: - To provide the IN value before the SQL statement is run. - To determine the size of the out value.
n	(Optional) Name the bind variable. For example, in SELECT * FROM emp WHERE ename=:ename, the position of the bind variable :ename is 1, the name is :ename. This parameter can be used if the non-Oracle system supports "named binds" instead of positional binds. Passing the position is still required.

Exceptions

Table 91-5 BIND_INOUT_VARIABLE_RAW Procedure Exceptions

Exception	Description
ORA-28550	The cursor passed is invalid.
ORA-28552	Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?)
ORA-28553	The position of the bind variable is out of range.
ORA-28555	A NULL value was passed for a NOT NULL parameter.

91.3.3 BIND_OUT_VARIABLE Procedure

This procedure binds an OUT variable with a PL/SQL program variable.

Syntax

```
DBMS_HS_PASSTHROUGH.BIND_OUT_VARIABLE (
   c      IN  BINARY_INTEGER NOT NULL,
   p      IN  BINARY_INTEGER NULL,
   v      OUT <dty>,
   n      IN  VARCHAR2);
```

<dty> is either DATE, NUMBER, or VARCHAR2.

> **See Also:**
>
> For binding OUT variables of datatype RAW, see BIND_OUT_VARIABLE_RAW Procedure.

Pragmas

```
Purity level defined : WNDS, RNDS
```

Parameters

Table 91-6 BIND_OUT_VARIABLE Procedure Parameters

Parameter	Description
c	Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines OPEN_CURSOR and PARSE respectively.
p	Position of the bind variable in the SQL statement: Starts at 1.
v	Variable in which the OUT bind variable stores its value. The package remembers only the "size" of the variable. After the SQL statement is run, you can use GET_VALUE to retrieve the value of the OUT parameter. The size of the retrieved value should not exceed the size of the parameter that was passed using BIND_OUT_VARIABLE.
n	(Optional) Name of the bind variable. For example, in SELECT * FROM emp WHERE ename=:ename, the position of the bind variable :ename is 1, the name is :ename. This parameter can be used if the non-Oracle system supports "named binds" instead of positional binds. Passing the position is still required.

Exceptions

Table 91-7 BIND_OUT_VARIABLE Procedure Exceptions

Exception	Description
ORA-28550	The cursor passed is invalid.
ORA-28552	Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?)
ORA-28553	The position of the bind variable is out of range.
ORA-28555	A NULL value was passed for a NOT NULL parameter.

91.3.4 BIND_OUT_VARIABLE_RAW Procedure

This procedure binds an OUT variable of datatype RAW with a PL/SQL program variable.

Syntax

```
DBMS_HS_PASSTHROUGH.BIND_OUT_VARIABLE_RAW (
   c     IN  BINARY_INTEGER NOT NULL,
   p     IN  BINARY_INTEGER NOT NULL,
```

```
   v     OUT RAW,
   n     IN  VARCHAR2);
```

Pragmas

```
Purity level defined : WNDS, RNDS
```

Parameters

Table 91-8 BIND_OUT_VARIABLE_RAW Procedure Parameters

Parameter	Description
c	Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines OPEN_CURSOR and PARSE respectively.
p	Position of the bind variable in the SQL statement: Starts at 1.
v	Variable in which the OUT bind variable stores its value. The package remembers only the "size" of the variable. After the SQL statement is run, you can use GET_VALUE to retrieve the value of the OUT parameter. The size of the retrieved value should not exceed the size of the parameter that was passed using BIND_OUT_VARIABLE_RAW.
n	(Optional) Name of the bind variable. For example, in SELECT * FROM emp WHERE ename=:ename, the position of the bind variable :ename is 1, the name is :ename. This parameter can be used if the non-Oracle system supports "named binds" instead of positional binds. Passing the position is still required.

Exceptions

Table 91-9 BIND_OUT_VARIABLE_RAW Procedure Exceptions

Exception	Description
ORA-28550	The cursor passed is invalid.
ORA-28552	Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?)
ORA-28553	The position of the bind variable is out of range.
ORA-28555	A NULL value was passed for a NOT NULL parameter.

91.3.5 BIND_VARIABLE Procedure

This procedure binds an IN variable positionally with a PL/SQL program variable.

Syntax

```
DBMS_HS_PASSTHROUGH.BIND_VARIABLE (
   c      IN BINARY_INTEGER NOT NULL,
   p      IN BINARY_INTEGER NOT NULL,
   v      IN <dty>,
   n      IN VARCHAR2);
```

<dty> is either DATE, NUMBER, or VARCHAR2.

> **See Also:**
>
> To bind RAW variables use BIND_VARIABLE_RAW Procedure.

Pragmas

```
Purity level defined: WNDS, RNDS
```

Parameters

Table 91-10 BIND_VARIABLE Procedure Parameters

Parameter	Description
c	Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed using the routines OPEN_CURSOR and PARSE respectively.
p	Position of the bind variable in the SQL statement: Starts at 1.
v	Value that must be passed to the bind variable name.
n	(Optional) Name of the bind variable. For example, in SELECT * FROM emp WHERE ename=:ename, the position of the bind variable :ename is 1, the name is :ename. This parameter can be used if the non-Oracle system supports "named binds" instead of positional binds. Passing the position is still required.

Exceptions

Table 91-11 BIND_VARIABLE Procedure Exceptions

Exception	Description
ORA-28550	The cursor passed is invalid.
ORA-28552	Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?)
ORA-28553	The position of the bind variable is out of range.
ORA-28555	A NULL value was passed for a NOT NULL parameter.

91.3.6 BIND_VARIABLE_RAW Procedure

This procedure binds IN variables of type RAW.

Syntax

```
DBMS_HS_PASSTHROUGH.BIND_VARIABLE_RAW (
   c    IN BINARY_INTEGER NOT NULL,
   p    IN BINARY_INTEGER NOT NULL,
   v    IN RAW,
   n    IN VARCHAR2);
```

Pragmas

```
Purity level defined : WNDS, RNDS
```

Parameters

Table 91-12 BIND_VARIABLE_RAW Procedure Parameters

Parameter	Description
c	Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines OPEN_CURSOR and PARSE respectively.
p	Position of the bind variable in the SQL statement: Starts at 1.
v	Value that must be passed to the bind variable.
n	(Optional) Name of the bind variable. For example, in SELECT * FROM emp WHERE ename=:ename, the position of the bind variable :ename is 1, the name is :ename. This parameter can be used if the non-Oracle system supports "named binds" instead of positional binds. Passing the position is still required.

Exceptions

Table 91-13 BIND_VARIABLE_RAW Procedure Exceptions

Exception	Description
ORA-28550	The cursor passed is invalid.
ORA-28552	Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?)
ORA-28553	The position of the bind variable is out of range.
ORA-28555	A NULL value was passed for a NOT NULL parameter.

91.3.7 CLOSE_CURSOR Procedure

This function closes the cursor and releases associated memory after the SQL statement has been run at the non-Oracle system. If the cursor was not open, then the operation is a "no operation".

Syntax

```
DBMS_HS_PASSTHROUGH.CLOSE_CURSOR (
   c IN BINARY_INTEGER NOT NULL);
```

Pragmas

```
Purity level defined : WNDS, RNDS
```

Parameters

Table 91-14 CLOSE_CURSOR Procedure Parameters

Parameter	Description
C	Cursor to be released.

Exceptions

Table 91-15 CLOSE_CURSOR Procedure Exceptions

Exception	Description
ORA-28555	A NULL value was passed for a NOT NULL parameter.

91.3.8 EXECUTE_IMMEDIATE Procedure

This function runs a SQL statement immediately. Any valid SQL command except SELECT can be run immediately.

The statement must not contain any bind variables. The statement is passed in as a VARCHAR2 in the argument. Internally the SQL statement is run using the PASSTHROUGH SQL protocol sequence of OPEN_CURSOR, PARSE, EXECUTE_NON_QUERY, CLOSE_CURSOR.

Syntax

```
DBMS_HS_PASSTHROUGH.EXECUTE_IMMEDIATE (
   s IN VARCHAR2 NOT NULL)
RETURN BINARY_INTEGER;
```

Parameters

Table 91-16 EXECUTE_IMMEDIATE Procedure Parameters

Parameter	Description
S	VARCHAR2 variable with the statement to be executed immediately.

Return Values

The number of rows affected by the execution of the SQL statement.

Exceptions

Table 91-17 EXECUTE_IMMEDIATE Procedure Exceptions

Exception	Description
ORA-28551	SQL statement is invalid.
ORA-28554	Max open cursors.
ORA-28555	A NULL value was passed for a NOT NULL parameter.

91.3.9 EXECUTE_NON_QUERY Function

This function runs a SQL statement. The SQL statement cannot be a SELECT statement. A cursor has to be open and the SQL statement has to be parsed before the SQL statement can be run.

Syntax

```
DBMS_HS_PASSTHROUGH.EXECUTE_NON_QUERY (
   c IN BINARY_INTEGER NOT NULL)
  RETURN BINARY_INTEGER;
```

Parameters

Table 91-18 EXECUTE_NON_QUERY Function Parameters

Parameter	Description
c	Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines OPEN_CURSOR and PARSE respectively.

Return Values

The number of rows affected by the SQL statement in the non-Oracle system

Exceptions

Table 91-19 EXECUTE_NON_QUERY Function Exceptions

Exception	Description
ORA-28550	The cursor passed is invalid.
ORA-28552	Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?)
ORA-28555	A NULL value was passed for a NOT NULL parameter.

91.3.10 FETCH_ROW Function

This function fetches rows from a result set.

The result set is defined with a SQL SELECT statement. When there are no more rows to be fetched, the exception NO_DATA_FOUND is raised. Before the rows can be fetched, a cursor has to be opened, and the SQL statement has to be parsed.

Syntax

```
DBMS_HS_PASSTHROUGH.FETCH_ROW (
   c   IN BINARY_INTEGER NOT NULL,
   f   IN BOOLEAN)
  RETURN BINARY_INTEGER;
```

Pragmas

```
Purity level defined : WNDS
```

Parameters

Table 91-20 FETCH_ROW Function Parameters

Parameter	Description
c	Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines OPEN_CURSOR and PARSE respectively.
first	(Optional) Reexecutes SELECT statement. Possible values: - TRUE: reexecute SELECT statement. - FALSE: fetch the next row, or if run for the first time, then execute and fetch rows (default).

Return Values

The returns the number of rows fetched. The function returns "0" if the last row was already fetched.

Exceptions

Table 91-21 FETCH_ROW Function Exceptions

Exception	Description
ORA-28550	The cursor passed is invalid.
ORA-28552	Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?)
ORA-28555	A NULL value was passed for a NOT NULL parameter.

91.3.11 GET_VALUE Procedure

This procedure has two purposes: it retrieves the select list items of SELECT statements after a row has been fetched, and it retrieves the OUT bind values, after the SQL statement has been run.

Syntax

```
DBMS_HS_PASSTHROUGH.GET_VALUE (
   c      IN  BINARY_INTEGER NOT NULL,
   p    IN  BINARY_INTEGER NOT NULL,
   v    OUT <dty>);
```

<dty> is either DATE, NUMBER, or VARCHAR2.

> **See Also:**
>
> For retrieving values of datatype RAW, see GET_VALUE_RAW Procedure.

Pragmas

```
Purity level defined : WNDS
```

Parameters

Table 91-22 GET_VALUE Procedure Parameters

Parameter	Description
c	Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines OPEN_CURSOR and PARSE respectively.
p	Position of the bind variable or select list item in the SQL statement: Starts at 1.
v	Variable in which the OUT bind variable or select list item stores its value.

Exceptions

Table 91-23 GET_VALUE Procedure Exceptions

Exception	Description
ORA-1403	Returns NO_DATA_FOUND exception when running the GET_VALUE after the last row was fetched (that is, FETCH_ROW returned "0").
ORA-28550	The cursor passed is invalid.
ORA-28552	Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?)
ORA-28553	The position of the bind variable is out of range.
ORA-28555	A NULL value was passed for a NOT NULL parameter.

91.3.12 GET_VALUE_RAW Procedure

This procedure is similar to GET_VALUE, but for datatype RAW.

Syntax

```
DBMS_HS_PASSTHROUGH.GET_VALUE_RAW (
   c    IN  BINARY_INTEGER NOT NULL,
   p    IN  BINARY_INTEGER NOT NULL,
   v    OUT RAW);
```

Pragmas

```
Purity level defined : WNDS
```

Parameters

Table 91-24 GET_VALUE_RAW Procedure Parameters

Parameter	Description
c	Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines OPEN_CURSOR and PARSE respectively.
p	Position of the bind variable or select list item in the SQL statement: Starts at 1.
v	Variable in which the OUT bind variable or select list item stores its value.

Exceptions

Table 91-25 GET_VALUE_RAW Procedure Exceptions

Exception	Description
ORA-1403	Returns NO_DATA_FOUND exception when running the GET_VALUE after the last row was fetched (that is, FETCH_ROW returned "0").
ORA-28550	The cursor passed is invalid.
ORA-28552	Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?)
ORA-28553	The position of the bind variable is out of range.
ORA-28555	A NULL value was passed for a NOT NULL parameter.

91.3.13 OPEN_CURSOR Function

This function opens a cursor for running a passthrough SQL statement at the non-Oracle system. This function must be called for any type of SQL statement.

The function returns a cursor, which must be used in subsequent calls. This call allocates memory. To deallocate the associated memory, call the procedure CLOSE_CURSOR.

Syntax

```
DBMS_HS_PASSTHROUGH.OPEN_CURSOR
  RETURN BINARY_INTEGER;
```

Pragmas

```
Purity level defined : WNDS, RNDS
```

Return Values

The cursor to be used on subsequent procedure and function calls.

Exceptions

Table 91-26 OPEN_CURSOR Function Exceptions

Exception	Description
ORA-28554	Maximum number of open cursor has been exceeded. Increase Heterogeneous Services' OPEN_CURSORS initialization parameter.

91.3.14 PARSE Procedure

This procedure parses an SQL statement at a non-Oracle system.

Syntax

```
DBMS_HS_PASSTHROUGH.PARSE (
   c       IN  BINARY_INTEGER NOT NULL,
   stmt    IN  VARCHAR2 NOT NULL);
```

Pragmas

```
Purity level defined : WNDS, RNDS
```

Parameters

Table 91-27 PARSE Procedure Parameters

Parameter	Description
c	Cursor associated with the passthrough SQL statement. Cursor must be opened using function OPEN_CURSOR.
stmt	Statement to be parsed.

Exceptions

Table 91-28 PARSE Procedure Exceptions

Exception	Description
ORA-28550	The cursor passed is invalid.
ORA-28551	SQL statement is illegal.
ORA-28555	A NULL value was passed for a NOT NULL parameter.

92
DBMS_ILM

The DBMS_ILM package provides an interface for implementing Information Lifecycle Management (ILM) strategies using Automatic Data Optimization (ADO) policies.

This chapter contains the following topics:

- Overview
- Security Model
- Constants
- Exceptions
- Summary of DBMS_ILM Subprograms

> **See Also:**
>
> - *Oracle Database VLDB and Partitioning Guide* for information about managing Automatic Data Optimization (ADO) with this package
> - DBMS_ILM_ADMIN
> - DBMS_HEAT_MAP

92.1 DBMS_ILM Overview

To implement your ILM strategy, you can use Heat Map in Oracle Database to track data access and modification. You can also use Automatic Data Optimization (ADO) to automate the compression and movement of data between different tiers of storage within the database. The DBMS_ILM package supports immediate evaluation or execution of ADO related tasks. T

he package supports the following two ways for scheduling ADO actions.

- A database user schedules immediate ADO policy execution on a set of objects.
- A database user views the results of evaluation of ADO policies on a set of objects. The user then adds or deletes objects to this set and reviews the results of ADO policy evaluation again. The user repeats this step to determine the set of objects for ADO execution. The user can then schedule ADO actions for immediate execution on this set of objects.

The following procedures support the two usage modes. Before describing the procedures, we introduce the notion of an ADO task as an entity that helps to track a particular evaluation or (an evaluation and execution) of ADO policies. A particular ADO task could be in one of the following states.

- Inactive
- Active

- Completed

92.2 DBMS_ILM Security Model

The DBMS_ILM package runs under invoker's rights.

92.3 DBMS_ILM Constants

The table in this topic lists the constants used by the DBMS_ILM package.

Table 92-1 DBMS_ILM Constants

Constant	Value	Type	Description
ILM_ALL_POLICIES	'ALL POLICIES'	VARCHAR2(20)	Selects all ADO policies on an object
ILM_EXECUTION_OFFLINE	1	NUMBER	Specifies that the object may be offline while ADO action is performed
ILM_EXECUTION_ONLINE	2	NUMBER	Specifies that the object should be online while ADO action is performed
SCOPE_DATABASE	1	NUMBER	Selects all ADO policies in the database
SCOPE_SCHEMA	2	NUMBER	Selects all ADO policies in the current schema
SCHEDULE_IMMEDIATE	1	NUMBER	Schedules ADO task for immediate execution
ARCHIVE_STATE_ACTIVE	'0'	VARCHAR2(1)	Represents the value of the ORA_ARCHIVE_STATE column of a row-archival enabled table that would make the row active
ARCHIVE_STATE_ARCHIVED	'1'	VARCHAR2(1)	Represents the value of the ORA_ARCHIVE_STATE column of a row-archival enabled table that would make the row inactive

92.4 DBMS_ILM Exceptions

The table in this topic lists the exceptions raised by the DBMS_ILM package.

Table 92-2 DBMS_ILM Exceptions

Exception	Error Code	Description
INVALID_ARGUMENT_VALUE	38327	Invalid argument value
INVALID_ILM_DICTIONARY	38328	Inconsistent dictionary state
INTERNAL_ILM_ERROR	38329	Internal error
INSUFFICIENT_PRIVILEGES	38330	Insufficient privileges

92.5 Summary of DBMS_ILM Subprograms

Thi table lists and describes the DBMS_ILM package subprograms.

Table 92-3 DBMS_ILM Package Subprograms

Subprogram	Description
ADD_TO_ILM Procedure	Adds the object specified through the argument to a particular ADO task and evaluates the ADO policies on this object
ARCHIVESTATENAME Function	Returns the value of the ORA_ARCHIVE_STATE column of a row-archival enabled table
EXECUTE_ILM Procedure	Executes an ADO task.
EXECUTE_ILM_TASK Procedure	Executes an ADO task that has been evaluated previously
PREVIEW_ILM Procedure	Evaluates all ADO policies in the scope specified by means of an argument
REMOVE_FROM_ILM Procedure	Removes the object specified through the argument from a particular ADO task
STOP_ILM Procedure	Stops ADO-related jobs created for a particular ADO task

92.5.1 ADD_TO_ILM Procedure

This procedure adds the object specified through the argument to a particular ADO task and evaluates the ADO policies on this object.

The procedure can only be executed on an ADO task in an inactive state. The results of the ADO policy evaluation on this object can be viewed using the appropriate views depending on role and access (USER_ILMTASKS or DBA_ILMTASKS, USER_ILMEVALUATIONDETAILS or DBA_ILMEVALUATIONDETAILS, USER_ILMRESULTS or DBA_ILMRESULTS).

Syntax

```
DBMS_ILM.ADD_TO_ILM (
   task_id           IN    NUMBER,
   owner             IN    VARCHAR2,
   object_name       IN    VARCHAR2,
   subobject_name    IN    VARCHAR2 DEFAULT NULL);
```

Parameters

Table 92-4 *ADD_TO_ILM Procedure Parameters*

Parameter	Description
task_id	Identifies a particular ADO task
owner	Owner of the object
object_name	Name of the object
subobject_name	Name of the subobject (partition name in the case of partitioned tables)

92.5.2 ARCHIVESTATENAME Function

This function returns the value of the `ORA_ARCHIVE_STATE` column of a row-archival enabled table.

Syntax

```
DBMS_ILM.ARCHIVESTATENAME (
   value      IN  VARCHAR2)
 RETURN VARCHAR2;
```

Parameters

Table 92-5 *ARCHIVESTATENAME Function Parameters*

Parameter	Description
`value`	Value for which the archive state name is to be returned

Usage Notes

Returns `ARCHIVE_STATE_ACTIVE` for `0`, `ARCHIVE_STATE_ARCHIVED` for others

> **See Also:**
>
> "Using In-Database Archiving" in *Oracle Database VLDB and Partitioning Guide*

92.5.3 EXECUTE_ILM Procedure

This procedure executes an ADO task.

There are two overloads to this procedure. The first overload executes an ADO task for a set of objects without having evaluated them previously. The second overload executes ADO policies for a specific object.

Syntax

```
DBMS_ILM.EXECUTE_ILM (
   task_id             OUT    NUMBER,
   ilm_scope           IN     NUMBER DEFAULT SCOPE_SCHEMA,
   execution_mode      IN     NUMBER DEFAULT ILM_EXECUTION_ONLINE);

DBMS_ILM.EXECUTE_ILM (
   owner               IN     VARCHAR2,
   object_name         IN     VARCHAR2,
   task_id             OUT    NUMBER,
   subobject_name      IN     VARCHAR2 DEFAULT NULL,
   policy_name         IN     VARCHAR2 DEFAULT ILM_ALL_POLICIES,
   execution_mode      IN     NUMBER DEFAULT ILM_EXECUTION_ONLINE);
```

Parameters

Table 92-6 *EXECUTE_ILM Procedure Parameters*

Parameter	Description
task_id	Identifies a particular ADO task
ilm_scope	Determines the set of objects considered for ADO execution. The default is to consider only the objects in the schema.
execution_mode	Whether the ADO task be executed online (ILM_EXECUTION_ONLINE) or offline (ILM_EXECUTION_OFFLINE)
owner	Owner of the object
object_name	Name of the object
subobject_name	Name of the subobject (partition name in the case of partitioned tables)
policy_name	Name of the ADO policy to be evaluated on the object. The package constant ILM_ALL_POLICIES should be used if all ADO policies on an object should be evaluated.

Usage Notes

- The EXECUTE_ILM procedure can be used by users who want more control of when ADO is performed, and who do not want to wait until the next maintenance window.
- The procedure executes like a DDL in that it auto commits before and after the ADO task and related jobs are created.

92.5.4 EXECUTE_ILM_TASK Procedure

This procedure executes an ADO task that has been evaluated previously and moves it to an active state.

Syntax

```
DBMS_ILM.EXECUTE_ILM_TASK (
   task_id             IN     NUMBER,
   execution_mode      IN     NUMBER DEFAULT ILM_EXECUTION_ONLINE);
   execution_schedule  IN     NUMBER DEFAULT SCHEDULE_IMMEDIATE);
```

Parameters

Table 92-7 *EXECUTE_ILM_TASK Procedure Parameters*

Parameter	Description
task_id	Identifies a particular ADO task
execution_mode	Whether the ADO task be executed online (ILM_EXECUTION_ONLINE) or offline (ILM_EXECUTION_OFFLINE)
execution_schedule	Identifies when the ADO task should be executed.Currently, the only choice available is immediate scheduling of ADO jobs

92.5.5 PREVIEW_ILM Procedure

This procedure evaluates the ADO policies on the objects specified using the `ILM_SCOPE` argument.

It returns a number as `task_id` which identifies a particular ADO task. This can be used to view the results of the policy evaluation in the appropriate views depending on role and access (`USER_ILMTASKS` or `DBA_ILMTASKS`, `USER_ILMEVALUATIONDETAILS` or `DBA_ILMEVALUATIONDETAILS`, `USER_ILMRESULTS` or `DBA_ILMRESULTS`).

The `PREVIEW_ILM` procedure leaves the ADO task in an inactive state. Once you have previewed the results, you can add or delete objects to this task.

Syntax

```
DBMS_ILM.PREVIEW_ILM (
   task_id           OUT    NUMBER,
  ilm_scope          IN     NUMBER DEFAULT SCOPE_SCHEMA);
```

Parameters

Table 92-8 *PREVIEW_ILM Procedure Parameters*

Parameter	Description
`task_id`	Identifies a particular ADO task
`ilm_scope`	Identifies the scope of execution. Should be either `SCOPE_DATABASE` or `SCOPE_SCHEMA` as described in Constants

92.5.6 REMOVE_FROM_ILM Procedure

This procedure removes the object specified through the argument from a particular ADO task.

The procedure can only be executed on an ADO task in an inactive state.

Syntax

```
DBMS_ILM.REMOVE_FROM_ILM (
   task_id           IN    NUMBER,
   owner             IN    VARCHAR2,
   object_name       IN    VARCHAR2,
   subobject_name    IN    VARCHAR2 DEFAULT NULL);
```

Parameters

Table 92-9 *REMOVE_FROM_ILM Procedure Parameters*

Parameter	Description
`task_id`	Identifies a particular ADO task
`owner`	Owner of the object
`object_name`	Name of the object

Table 92-9 (Cont.) *REMOVE_FROM_ILM Procedure Parameters*

Parameter	Description
subobject_name	Name of the subobject (partition name in the case of partitioned tables)

92.5.7 STOP_ILM Procedure

This procedure terminates ILM ADO jobs associated to a particular task Id or job name.

Syntax

```
DBMS_ILM.STOP_ILM (
   task_id               IN         NUMBER,
   p_drop_running_jobs   IN         BOOLEAN  DEFAULT FALSE),
   p_jobname             IN         VARCHAR2 DEFAULT NULL);
```

Parameters

Table 92-10 *STOP_ILM Procedure Parameters*

Parameter	Description
task_id	Number that uniquely identifies a particular ADO task
p_drop_running_jobs	Determines whether running jobs are dropped
p_jobname	Name of job to be terminated

93
DBMS_ILM_ADMIN

The `DBMS_ILM_ADMIN` package provides an interface to customize Automatic Data Optimization (ADO) policy execution. In combination with partitioning and compression, ADO policies can be used to help implement an Information Lifecycle Management (ILM) strategy.

This chapter contains the following topics:

- Overview
- Security Model
- Constants
- Summary of DBMS_ILM_ADMIN Subprograms

> **See Also:**
>
> - *Oracle Database VLDB and Partitioning Guide* for information about managing Automatic Data Optimization (ADO) with this package
> - DBMS_ILM
> - DBMS_HEAT_MAP

93.1 DBMS_ILM_ADMIN Overview

To implement your ILM strategy, you can use Heat Map in Oracle Database to track data access and modification. You can also use Automatic Data Optimization (ADO) to automate the compression and movement of data between different tiers of storage within the database.

93.2 DBMS_ILM_ADMIN Security Model

This package runs under definer's rights. The user requires DBA privileges.

93.3 DBMS_ILM_ADMIN Constants

The table in this topic describes constants used by the `DBMS_ILM_ADMIN` package.

The value column refers to the numeric or character value that the constants resolve to.

Table 93-1 DBMS_ILM_ADMIN Constants

Constant	Value	Type	Description
ABS_JOBLIMIT	12	NUMBER	Specifies the absolute number of concurrent ILM ADO jobs.
EXECUTION_INTERVAL	1	NUMBER	Determines the frequency with which ADO background evaluation occurs. Specified in minutes.
RETENTION_TIME	2	NUMBER	Controls the amount of time ADO history should be maintained. Specified in days.
EXECUTION_MODE	4	NUMBER	Controls whether ADO execution is online, offline. The value for this parameter should either be DBMS_ILM_ADMIN.ILM_EXECUTION_OFFLINE or DBMS_ILM_ADMIN.ILM_EXECUTION_ONLINE.
JOBLIMIT	5	NUMBER	Controls the upper limit on number of ILM ADO jobs at any time. The maximum number of concurrent ADO jobs is JOBLIMIT*(number of instances)*(number of CPUs per instance).
JOB_SIZELIMIT	13	NUMBER	Specifies the size (in megabytes) of the data that is processed by a single ILM ADO row level compression job.
ENABLED	7	NUMBER	Provides a way to turn background ADO off or on
TBS_PERCENT_USED	8	NUMBER	Decides when a tablespace is considered full. Specified as a percentage of tablespace quota.
TBS_PERCENT_FREE	9	NUMBER	Decides the targeted tablespace storage through ADO actions as a percentage of tablespace quota.
DEG_PARALLEL	10	NUMBER	Decides the degree of parallelism to be used for ADO jobs
POLICY_TIME	11	NUMBER	Decides if ADO policies are treated as though they are specified in seconds rather than days. Can take value ILM_POLICY_IN_SECONDS (treat policy time in seconds) or ILM_POLICY_IN_DAYS (treat policy time in days - default).
HEAT_MAP_SEG_READ	1	NUMBER	Segment read done
HEAT_MAP_SEG_WRITE	2	NUMBER	Segment write done
HEAT_MAP_SEG_SCAN	4	NUMBER	Full table scan done
HEAT_MAP_SEG_LOOKUP	8	NUMBER	Index scan done

The DBMS_ILM_ADMIN package uses the constants as parameter values shown in Table 93-2.

Table 93-2 DBMS_ILM_ADMIN Constants Used as Parameter Values

Constant	Value	Type	Description
ILM_EXECUTION_OFFLINE	1	NUMBER	Specifies that the object may be offline while ADO action is performed.
ILM_EXECUTION_ONLINE	2	NUMBER	Specifies that the object should be online while ADO action is performed
ILM_ENABLED	1	NUMBER	Indicates automatic ADO policy evaluation and execution is enabled
ILM_DISABLED	2	NUMBER	Indicates automatic ADO policy evaluation and execution is disabled
ILM_POLICY_IN_DAYS	0	NUMBER	Indicates policy is specified in days. This is the default.
ILM_POLICY_IN_SECONDS	1	NUMBER	Indicates policy is specified in seconds (rather than days). This could be used to test ADO policy evaluation quickly instead of waiting for the policy duration.

93.4 Summary of DBMS_ILM_ADMIN Subprograms

This table lists and briefly describes the DBMS_ILM_ADMIN package subprograms.

Table 93-3 DBMS_ILM_ADMIN Package Subprograms

Subprogram	Description
CLEAR_HEAT_MAP_ALL Procedure	Deletes all rows except the dummy row
CLEAR_HEAT_MAP_TABLE Procedure	Clears all or some statistics for the heat map table, deleting rows for a given table or segment which match a given pattern, or all such rows
CUSTOMIZE_ILM Procedure	Customizes environment for ILM execution by specifying the values for ILM execution related parameters
DISABLE_ILM Procedure	Turns off all background ILM scheduling
ENABLE_ILM Procedure	Turns on all background ILM scheduling
SET_HEAT_MAP_ALL Procedure	Updates or inserts heat map rows for all tables
SET_HEAT_MAP_START Procedure	Sets the start date for collecting heat map data
SET_HEAT_MAP_TABLE Procedure	Updates or inserts a row for the specified table or segment

93.4.1 CLEAR_HEAT_MAP_ALL Procedure

This procedure deletes all rows in HEAT_MAP_STAT$ except the dummy row.

Syntax

```
DBMS_ILM_ADMIN.CLEAR_HEAT_MAP_ALL;
```

93.4.2 CLEAR_HEAT_MAP_TABLE Procedure

This procedure clears all or some statistics for the heat map table, deleting rows for a given table or segment which match a given pattern, or all such rows.

Syntax

```
DBMS_ILM_ADMIN.CLEAR_HEAT_MAP_TABLE  (
   owner                   IN  VARCHAR2,
   tablename               IN  VARCHAR2,
   partition               IN  VARCHAR2 default '',
   access_date             IN  DATE DEFAULT NULL,
   segment_access_summary  IN  NUMBER DEFAULT NULL);
```

Parameters

Table 93-4 *CLEAR_HEAT_MAP_TABLE Procedure Parameters*

Parameter	Description
owner	Table owner
tablename	Table name
partition	Name of the subobject, defaults to NULL
access_date	Date for the entry in HEAT_MAP_STAT$ to be removed
segment_access_summary	Summary of segment access constants indicating access operations performed on the segment

93.4.3 CUSTOMIZE_ILM Procedure

This procedure customizes environment for ILM execution by specifying the values for ILM execution related parameters. These values take effect for the next background scheduling.

Syntax

```
DBMS_ILM_ADMIN.CUSTOMIZE_ILM  (
   parameter            IN       NUMBER,
   value                IN       NUMBER);
```

Parameters

Table 93-5 *CUSTOMIZE_ILM Procedure Parameters*

Parameter	Description
parameter	One of the parameter constants defined in DBMS_ILM_ADMIN package
value	Value of parameter

93.4.4 DISABLE_ILM Procedure

This procedure turns off all background ILM scheduling.

Syntax

```
DBMS_ILM_ADMIN.DISABLE_ILM;
```

93.4.5 ENABLE_ILM Procedure

This procedure turns on all background ILM scheduling.

Syntax

```
DBMS_ILM_ADMIN.ENABLE_ILM;
```

93.4.6 SET_HEAT_MAP_ALL Procedure

This procedure sets an HTTP request header. The request header is sent to the Web server as soon as it is set.

Syntax

```
DBMS_ILM_ADMIN.SET_HEAT_MAP_ALL  (
   access_date            IN DATE,
   segment_access_summary IN NUMBER);
```

Parameters

Table 93-6 *SET_HEAT_MAP_ALL Procedure Parameters*

Parameter	Description
access_date	Date for the entry in HEAT_MAP_STAT$ to be added
segment_access_summary	Summary of segment access constants indicating access operations performed on the segment

93.4.7 SET_HEAT_MAP_START Procedure

This procedure sets the start date for collecting heat map data.

Syntax

```
DBMS_ILM_ADMIN.SET_HEAT_MAP_START  (
   start_date  IN   DATE);
```

Parameters

Table 93-7 *SET_HEAT_MAP_START Procedure Parameters*

Parameter	Description
start_date	Indicates the new date from which all statistics are valid

93.4.8 SET_HEAT_MAP_TABLE Procedure

This procedure updates or inserts a row for the specified table or segment.

Syntax

```
DBMS_ILM_ADMIN.SET_HEAT_MAP_TABLE  (
   owner                  IN VARCHAR2,
   tablename              IN VARCHAR2,
   partition              IN VARCHAR2 DEFAULT '',
   access_date            IN DATE DEFAULT NULL,
   segment_access_summary IN NUMBER DEFAULT NULL);
```

Parameters

Table 93-8 ***SET_HEAT_MAP_TABLE Procedure Parameters***

Parameter	Description
`owner`	Table owner
`tablename`	Table name
`partition`	Name of the subobject, defaults to `NULL`
`access_date`	Date for the entry in `HEAT_MAP_STAT$` to be added
`segment_access_summary`	Summary of segment access constants indicating access operations performed on the segment

94
DBMS_IMMUTABLE_TABLE

Immutable tables are read-only tables that protect data against unauthorized modification. They also prevent against accidental data modifications that may be caused by human errors. The `DBMS_IMMUTABLE_TABLE` package allows you to delete the expired rows in an immutable table.

This chapter contains the following topics:

- DBMS_IMMUTABLE_TABLE Overview
- DBMS_IMMUTABLE_TABLE Security Model
- Summary of DBMS_IMMUTABLE_TABLE Subprograms

> **See Also:**
>
> - *Oracle Database Administrator's Guide*
> - *Oracle Database SQL Language Reference*
> - *Oracle Database Reference*

94.1 DBMS_IMMUTABLE_TABLE Overview

Immutable tables are `read-only` tables that protect data against unauthorized modification. Immutable tables also prevent against accidental data modifications that may be caused by human errors. You must specify a retention period for the immutable table and for rows within the immutable table. An immutable table can be dropped if it contains no rows or if the specified retention period for the table has lapsed. Rows can be deleted from an immutable table only after the specified retention period for rows in the table has elapsed. Except for increasing the retention periods, you cannot modify the definition of an immutable table.

94.2 DBMS_IMMUTABLE_TABLE Security Model

The `DBMS_IMMUTABLE_TABLE` package is owned by `SYS` and is installed as part of database installation. The routines in the package are run with invoker's rights and hence run with the privileges of the current user.

94.3 Summary of DBMS_IMMUTABLE_TABLE Subprograms

This table lists the `DBMS_IMMUTABLE_TABLE` subprograms in alphabetical order and briefly describes them.

Table 94-1 DBMS_IMMUTABLE_TABLE Package Subprograms

Subprogram	Description
DELETE_EXPIRED_ROWS Procedure	This procedure deletes the expired rows.

94.3.1 DELETE_EXPIRED_ROWS Procedure

This procedure deletes some or all of the expired rows from the immutable table. This procedure does not commit.

Syntax

```
DBMS_IMMUTABLE_TABLE.DELETE_EXPIRED_ROWS(
   schema_name                 IN VARCHAR2,
   table_name                  IN VARCHAR2,
   before_timestamp            IN TIMESTAMP WITH TIME ZONE DEFAULT NULL,
   number_of_rows_deleted      OUT NUMBER);
```

Parameters

Table 94-2 DELETE_EXPIRED_ROWS Procedure Parameters

Parameter	Description
schema_name	The name of the schema.
table_name	The name of the immutable table.
before_timestamp	If the parameter is NULL, all expired rows in the table are deleted. If the parameter is not NULL and older than the timestamp calculated based on current time and row retention time, rows with timestamps less than the parameter value are deleted. If the parameter is younger than the timestamp calculated based on the current time and row retention time, the calculated timestamp is used, and all expired rows are deleted. The default value is NULL.
number_of_rows_deleted	The number of rows deleted.

95
DBMS_INMEMORY

The DBMS_INMEMORY package provides an interface for In-Memory Column Store (IM column store) functionality.

This chapter contains the following topics:

- DBMS_INMEMORY Overview
- DBMS_INMEMORY Security Model
- Summary of DBMS_INMEMORY Subprograms

95.1 DBMS_INMEMORY Overview

This package contains procedures for populating and repopulating the IM column store, and for dropping IM expressions from a specified table.

IM Population and Repopulation

In-Memory population (population) occurs when the database reads existing row-format data from disk, transforms it into columnar format, and then stores it in the IM column store. Only objects with the INMEMORY attribute are eligible for population.

Population, which transforms existing data on disk into columnar format, is different from repopulation, which loads new data into the IM column store. Repopulation occurs automatically after their columnar data undergo significant DML activity.

When an object has the INMEMORY attribute and a priority other than NONE, the database gradually populates the object in the IM column store according to an internal priority queue. Objects with priority of NONE are populated only when they undergo a full scan.

The DBMS_INMEMORY.POPULATE procedure forces immediate population of an object. The DBMS_INMEMORY.REPOPULATE procedure forces immediate repopulation of an object.

> **See Also:**
>
> *Oracle Database In-Memory Guide* to learn more about IM population

IM Expressions

IM expressions populate frequently evaluated query expressions in the IM column store for subsequent reuse. An IM expression is materialized as a hidden virtual column, prefixed with the string SYS_IME, and is accessed in the same way as a non-virtual column.

When you use DBMS_INMEMORY_ADMIN.IME_CAPTURE_EXPRESSIONS, the database adds the 20 hottest expressions to their respective tables as SYS_IME columns and applies the default INMEMORY column compression clause. If any SYS_IME columns that were added during a

previous invocation are no longer in the latest expression list, then the database changes their attribute to `NO INMEMORY`.

The maximum number of `SYS_IME` columns for a table, regardless of whether the attribute is `INMEMORY` or `NO INMEMORY`, is 50. After the 50 expression limit is reached for a table, the database will not add new `SYS_IME` columns. To make space for new expressions, you must manually drop `SYS_IME` columns with the `DBMS_INMEMORY.IME_DROP_EXPRESSIONS` or `DBMS_INMEMORY_ADMIN.IME_DROP_ALL_EXPRESSIONS` procedures.

> **See Also:**
>
> *Oracle Database In-Memory Guide* to learn more about IM expressions

95.2 DBMS_INMEMORY Security Model

The DBMS_INMEMORY package subprograms execute with invoker's rights.

The `POPULATE` and `REPOPULATE` procedures require the invoking user to have `SELECT` privileges on the specified object. For `IME_DROP_EXPRESSIONS`, the invoking user must have `ALTER TABLE` privileges on the specified table.

95.3 Summary of DBMS_INMEMORY Subprograms

This table lists and briefly describes the `DBMS_INMEMORY` package subprograms.

Table 95-1 DBMS_INMEMORY Package Subprograms

Subprogram	Description
IME_DROP_EXPRESSIONS Procedure	Drops a specified set of SYS_IME virtual columns from a table
POPULATE Procedure	Forces population of the specified table
REPOPULATE Procedure	Forces repopulation of the specified table
SEGMENT_DEALLOCATE_VERSIONS Procedure	Deallocates non-current IMCUs in the IM column store

95.3.1 IME_DROP_EXPRESSIONS Procedure

This procedure drops a specified set of `SYS_IME` virtual columns from a table.

Syntax

```
DBMS_INMEMORY.IME_DROP_EXPRESSIONS(
   schema_name    IN    VARCHAR2,
   table_name     IN    VARCHAR2,
   column_name    IN    VARCHAR2 DEFAULT NULL);
```

Parameters

Table 95-2 IME_DROP_EXPRESSIONS Procedure Parameters

Parameter	Description
schema_name	The name of the schema that contains the In-Memory table
table_name	The name of the In-Memory table that contains the SYS_IME columns
column_name	The name of the SYS_IME column. By default this value is null, which specifies all SYS_IME columns in this table.

Usage Notes

Typical reasons for dropping SYS_IME columns are space and performance. The maximum number of SYS_IME columns for a table, regardless of whether the attribute is INMEMORY or NO INMEMORY, is 50. After the 50-expression limit is reached for a table, the database will not add new SYS_IME columns. To make space for new expressions, you must manually drop SYS_IME columns with the DBMS_INMEMORY.IME_DROP_EXPRESSIONS or DBMS_INMEMORY_ADMIN.IME_DROP_ALL_EXPRESSIONS procedures.

To drop a specified SYS_IME column or all SYS_IME columns in the requested table, use DBMS_INMEMORY.IME_DROP_EXPRESSIONS . To populate these segments again, either invoke the DBMS_INMEMORY.POPULATE procedure, or perform a full table scan.

95.3.2 POPULATE Procedure

This procedure forces population of the specified table, partition, or subpartition into the IM column store.

Syntax

```
DBMS_INMEMORY.POPULATE(
   schema_name      IN    VARCHAR2,
   table_name       IN    VARCHAR2,
   subobject_name   IN    VARCHAR2 DEFAULT NULL);
```

Parameters

Table 95-3 *POPULATE Procedure Parameters*

Parameter	Description
schema_name	Name of schema
table_name	Name of table
subobject_name	Partition or subpartition

95.3.3 REPOPULATE Procedure

This procedure forces repopulation of a table, partition, or subpartition that is currently populated in the IM column store.

Syntax

```
DBMS_INMEMORY.REPOPULATE(
   schema_name      IN    VARCHAR2,
   table_name       IN    VARCHAR2,
   subobject_name   IN    VARCHAR2 DEFAULT NULL,
   force            IN    BOOLEAN DEFAULT FALSE);
```

Parameters

Table 95-4 REPOPULATE Procedure Parameters

Parameter	Description
`schema_name`	Name of the schema that owns the object.
`table_name`	Name of the table requiring repopulation.
`subobject_name`	Name of the partition or subpartition. If null, then repopulate the entire table.
`force`	Whether to repopulate all IMCUs in the segment, just as in initial population. The following values are possible for the `force` parameter: • FALSE — The database repopulates only IMCUs containing modified rows. This is the default. • TRUE — The database drops the segment, and then rebuilds it. The database increments the statistics and performs all other tasks related to initial population. For example, IMCU 1 contains rows 1 to 500,000, and IMCU 2 contains rows 500,001 to 1,000,000. A statement modifies row 600,000. When `force` is FALSE, the database only repopulates IMCU 2. When `force` is TRUE, the database repopulates both IMCUs. Consider further that the `INMEMORY_VIRTUAL_COLUMNS` initialization parameter is set to ENABLE, and an application creates a new virtual column. When `force` is FALSE, the database only repopulates IMCU 2 with the new column. When `force` is TRUE, the database repopulates both IMCUs with the new column.

95.3.4 SEGMENT_DEALLOCATE_VERSIONS Procedure

This procedure deallocates non-current IMCUs in the IM column store.

Syntax

```
DBMS_INMEMORY.SEGMENT_DEALLOCATE_VERSIONS(
   SCHEMA_NAME      IN  VARCHAR2,
```

```
   TABLE_NAME       IN  VARCHAR2,
   PARTITION_NAME   IN  VARCHAR2 DEFAULT NULL,
   SPCPRESSURE      IN  BOOLEAN DEFAULT FALSE);
```

Parameters

Table 95-5 SEGMENT_DEALLOCATE_VERSIONS Procedure Parameters

Parameter	Description
`schema_name`	Name of the schema that owns the object.
`table_name`	Name of the table requiring repopulation.
`partition_name`	Name of the partition or subpartition. If null, then repopulate the entire table.
`spcpressure`	Whether to force deallocation of non-current IMCUs (TRUE), or wait for the database to deallocate them automatically. By default, the database deallocates non-current IMCUs every two minutes.

Usage Notes

During repopulation, the IM column store maintains both the current IMCU and non-current IMCU. This mechanism, which is called *double buffering*, ensures that queries do not decrease performance because an IMCU is unavailable during repopulation. After repopulation completes, the IM column store retains the non-current IMCU for a short time (2 minutes by default) to optimize queries with older SCNs. Typically, the default behavior is sufficient. However, you can force deallocation of non-current IMCUs by using the `SEGMENT_DEALLOCATE_VERSIONS` procedure.

Example

The following program forces deallocation of non-current IMCUs for the `products` table:

```
BEGIN
  DBMS_INMEMORY.SEGMENT_DEALLOCATE_VERSIONS(
    schema_name => 'SH'
  , table_name  => 'PRODUCTS'
  , spcpressure => TRUE );
END;
```

> **See Also:**
>
> *Oracle Database In-Memory Guide* to learn more about double buffering in the IM column store

96
DBMS_INMEMORY_ADMIN

DBMS_INMEMORY_ADMIN provides interfaces for managing an In-Memory FastStart (IM FastStart) area and In-Memory Expressions (IM expressions).

This chapter contains the following topics:

- DBMS_INMEMORY_ADMIN Overview
- DBMS_INMEMORY_ADMIN Security Model
- DBMS_INMEMORY_ADMIN Operational Notes
- Summary of DBMS_INMEMORY_ADMIN Subprograms

> **See Also:**
>
> *Oracle Database In-Memory Guide* to learn more about Oracle Database In-Memory features

96.1 DBMS_INMEMORY_ADMIN Overview

This package provides interfaces for managing In-Memory Expressions (IM expressions) and the In-Memory FastStart (IM FastStart) area.

IM Expressions

Analytic queries often contain complex expressions or calculations that consume significant CPU and memory during execution. Use IME_CAPTURE_EXPRESSIONS to identify these frequently used ("hot") expressions and IME_POPULATE_EXPRESSIONS to populate them in the IM column store. By using IM expressions, the database avoids repeated computations and improves performance.

The database represents IM expressions as system-generated virtual columns. The name of an IM virtual column begins with SYS_IME. You can also use DBMS_INMEMORY_ADMIN.IME_DROP_ALL_EXPRESSIONS and DBMS_INMEMORY.IME_DROP_EXPRESSIONS to remove existing SYS_IME columns.

The DBA_IM_EXPRESSIONS view shows the SYS_IME columns that have the INMEMORY attribute. After using the IME_CAPTURE_EXPRESSIONS procedure, you can query this view to see the hot expressions added to different tables in the database.

> **See Also:**
>
> *Oracle Database In-Memory Guide* to learn more about IM expressions

IM FastStart Area

The IM FastStart area stores data that optimizes the population of the IM column store when the database restarts. Because the database reads columnar data directly from persistent storage without needing to compress or format it, population is faster when a database instance restarts.

When you enable IM FastStart for the IM column store, you must specify an ASSM tablespace for the IM FastStart area. The tablespace stores the data in a SecureFiles LOB named `SYSDBIMFS_LOGSEG$`. The `SYSAUX` tablespace stores the metadata. When data is populated or repopulated in the IM column store, the database automatically writes the data to the IM FastStart area. You cannot manually force a write. If you specify an object as `NO INMEMORY`, then the database removes it from the IM FastStart area.

When the IM FastStart area is under space pressure, the database automatically drops the oldest 15% of segments and continues saving columnar data. If space is unavailable, then the database stops writing to the IM FastStart area.

> **See Also:**
>
> *Oracle Database In-Memory Guide* to learn more about IM expressions

Automatic In-Memory

Automatic In-Memory uses access tracking and column statistics to manage objects in the IM column store. If the IM column store is full, and if other more frequently accessed segments would benefit from population in the IM column store, then the IM column store evicts inactive segments. If the IM column store is configured to hold all `INMEMORY` segments, however, then Automatic In-Memory takes no action.

By default, Automatic In-Memory checks usage statistics for the past 31 days. You can change the current setting by supplying the `AIM_STATWINDOW_DAYS` parameter to `DBMS_INMEMORY_ADMIN.AIM_SET_PARAMETER`.

> **See Also:**
>
> *Oracle Database In-Memory Guide* to learn more about Automatic In-Memory

Database In-Memory Wait on Populate

The `POPULATE_WAIT` function initiates population of all `INMEMORY` objects that have a priority greater than or equal to the specified priority, and then returns a status value for the population. A user-specified interval specifies the maximum time that the function waits before returning the value to the caller.

> **See Also:**
>
> *Oracle Database In-Memory Guide* to learn more about the wait on populate feature

96.2 DBMS_INMEMORY_ADMIN Security Model

This package requires administrator privileges. Package subprograms execute with invoker's rights.

96.3 DBMS_INMEMORY_ADMIN Operational Notes

It is possible for a `DBMS_INMEMORY_ADMIN` FastStart operation to fail or be interrupted.

In a failure or interruption scenario, the following rules determine which subprograms you can use:

- If `FASTSTART_ENABLE` does not succeed, then the only permitted operation is re-executing `FASTSTART_ENABLE`.
- If `FASTSTART_MIGRATE_STORAGE` does not succeed, then the only permitted operation is re-executing `FASTSTART_MIGRATE_STORAGE`.
- If `FASTSTART_DISABLE` does not succeed, then all `DBMS_INMEMORY_ADMIN` operations are permitted.

96.4 Summary of DBMS_INMEMORY_ADMIN Subprograms

This table lists the `DBMS_INMEMORY_ADMIN` subprograms and briefly describes them.

Table 96-1 DBMS_INMEMORY_ADMIN Package Subprograms

Subprogram	Description
AIM_GET_PARAMETER Procedure	This procedure obtains the current values for parameters that control Automatic In-Memory.
AIM_SET_PARAMETER Procedure	The procedure customizes the execution environment of Automatic In-Memory
FASTSTART_DISABLE Procedure	This procedure disables the In-Memory FastStart (IM FastStart) feature.
FASTSTART_ENABLE Procedure	This procedure enables IM FastStart and assigns a tablespace.
FASTSTART_MIGRATE_STORAGE Procedure	This procedure moves all IM FastStart data and metadata from the existing tablespace to the specified new tablespace.
GET_FASTSTART_TABLESPACE Function	This function returns the name of the tablespace that is currently designated for IM FastStart.
IME_CAPTURE_EXPRESSIONS Procedure	This procedure captures the 20 most frequently accessed ("hottest") expressions in the database in the specified time interval.

Table 96-1 (Cont.) DBMS_INMEMORY_ADMIN Package Subprograms

Subprogram	Description
IME_CLOSE_CAPTURE_WINDOW Procedure	This procedure signals the end of the current expression capture window.
IME_DROP_ALL_EXPRESSIONS Procedure	This procedure drops all SYS_IME expression virtual columns in the database.
IME_GET_CAPTURE_STATE Procedure	This procedure returns the current capture state of the expression capture window and the timestamp of the most recent modification.
IME_OPEN_CAPTURE_WINDOW Procedure	This procedure signals the beginning of an expression capture window.
IME_POPULATE_EXPRESSIONS Procedure	This procedure forces the population of expressions captured in the latest invocation of DBMS_INMEMORY_ADMIN.IME_CAPTURE_EXPRESSIONS.
POPULATE_WAIT Function	Initiates population of all INMEMORY objects that have a priority greater than or equal to the specified priority, and sets a timeout interval within which population must occur

96.4.1 AIM_GET_PARAMETER Procedure

This procedure obtains the current values for parameters that control Automatic In-Memory.

Syntax

```
DBMS_INMEMORY_ADMIN.AIM_GET_PARAMETER(
   parameter   IN    NUMBER,
   value       OUT   NUMBER);
```

Parameters

Parameter	Description
parameter	Specifies a predefined constant that controls Automatic In-Memory. The only valid constant is AIM_STATWINDOW_DAYS, which specifies the number of days in the sliding statistics window. Automatic In-Memory uses this duration to filter statistics for INMEMORY objects as part of its algorithms. For example, if the duration is set to 7 days, then Automatic In-Memory considers only statistics of the past 7 days for its algorithms. The default is 1.
value	Specifies the value assigned to AIM_STATWINDOW_DAYS.

Example 96-1 Getting the Number of Days in the Statistics Window

The following code prints the number of days in the statistics window to the screen:

```
VARIABLE b_statwin NUMBER
```

```
BEGIN

DBMS_INMEMORY_ADMIN.AIM_GET_PARAMETER(DBMS_INMEMORY_ADMIN.AIM_STATWINDOW_DAYS
, :b_statwin);
END;
/

PRINT b_statwin
```

Sample output appears below:

```
B_STATWIN
---------
       14
```

> **See Also:**
>
> *Oracle Database In-Memory Guide* to learn how to use `AIM_GET_PARAMETER`

96.4.2 AIM_SET_PARAMETER Procedure

The procedure customizes the execution environment of Automatic In-Memory.

Syntax

```
DBMS_INMEMORY_ADMIN.AIM_SET_PARAMETER(
   parameter   IN    NUMBER,
   value       IN    NUMBER);
```

Parameters

Parameter	Description
`parameter`	Specifies a predefined constant that controls Automatic In-Memory. The only valid constant is `AIM_STATWINDOW_DAYS`, which specifies the number of days in the sliding statistics window. The default is 1.
`value`	Assigns the value assigned to `AIM_STATWINDOW_DAYS`.

Example 96-2 Setting the Number of Days in the Statistics Window

The following example gets the current number of days in the window, sets it to 14, and then prints the value to the screen:

```
VARIABLE b_statwin NUMBER

BEGIN

DBMS_INMEMORY_ADMIN.AIM_GET_PARAMETER(DBMS_INMEMORY_ADMIN.AIM_STATWINDOW_DAYS
, :b_statwin);
END;
```

```
/

PRINT b_statwin

BEGIN

DBMS_INMEMORY_ADMIN.AIM_SET_PARAMETER(DBMS_INMEMORY_ADMIN.AIM_STATWINDOW
_DAYS, 14);
END;
/

BEGIN

DBMS_INMEMORY_ADMIN.AIM_GET_PARAMETER(DBMS_INMEMORY_ADMIN.AIM_STATWINDOW
_DAYS, :b_statwin);
END;
/

PRINT b_statwin
```

Sample output appears below:

```
 B_STATWIN
----------
         1

 B_STATWIN
----------
        14
```

96.4.3 FASTSTART_DISABLE Procedure

This procedure disables the In-Memory FastStart (IM FastStart) feature.

Syntax

```
DBMS_INMEMORY_ADMIN.FASTSTART_DISABLE();
```

Security Model

Administrator privileges are required to execute this procedure.

Usage Notes

When you execute the procedure, the database executes the following actions:

1. Waits until all IM FastStart operations complete

2. Disables the IM FastStart feature, and performs the following operations:
   - Cleans the IM FastStart area
   - Deletes IM FastStart metadata stored in the SYSAUX tablespace
   - Releases the IM FastStart tablespace (but does not delete it)

This procedure does not interrupt or affect any concurrent IM column store operations.

Examples

The following PL/SQL program disables the IM FastStart feature:

```
EXEC DBMS_INMEMORY_ADMIN.FASTSTART_DISABLE;
```

The following query shows that the LOB for the IM FastStart tablespace has been deleted (sample output included):

```
COL OWNER FORMAT a5
COL SEGMENT_NAME FORMAT a20
SELECT   l.OWNER, l.SEGMENT_NAME, SUM(s.BYTES)/1024/1024 MB
FROM     DBA_LOBS l, DBA_SEGMENTS s
WHERE    l.SEGMENT_NAME = s.SEGMENT_NAME
AND      l.TABLESPACE_NAME = 'FS_TBS'
GROUP BY l.OWNER, l.SEGMENT_NAME;

no rows selected
```

96.4.4 FASTSTART_ENABLE Procedure

This procedure enables In-Memory FastStart (IM FastStart), and designates a tablespace for the IM FastStart (FastStart) area.

> **Note:**
>
> A multitenant container database is the only supported architecture in Oracle Database 20c. While the documentation is being revised, legacy terminology may persist. In most cases, "database" and "non-CDB" refer to a CDB or PDB, depending on context. In some contexts, such as upgrades, "non-CDB" refers to a non-CDB from a previous release.

Syntax

```
DBMS_INMEMORY_ADMIN.FASTSTART_ENABLE(
   tbs_name    IN    VARCHAR2,
   nologging   IN    BOOLEAN DEFAULT TRUE);
```

Parameters

Table 96-2 FASTSTART_ENABLE Procedure Parameters

Parameter	Description
tbs_name	The name of the ASSM tablespace for the FastStart area.
nologging	The logging mode of the LOB created for the FastStart area. If the nologging parameter is set to FALSE, then the database creates the FastStart LOB with the LOGGING option. If set to TRUE (default), then the database creates the LOB with the NOLOGGING option.

Security Model

Administrator privileges are required to execute this procedure.

Usage Notes

To enable IM FastStart, the ASSM tablespace specified in FASTSTART_ENABLE must exist, and the SYSAUX tablespace must be online. Only one FastStart tablespace can exist for every PDB or non-CDB. The specified tablespace must have enough space to store data for the IM column store, and it must not contain any other data before it is designated for the FastStart area. Oracle recommends sizing the tablespace at least twice of the size of the INMEMORY_SIZE initialization parameter.

The database does not create the FastStart area on disk until the IM column store is populated. After population, the data periodically saves the columnar data (but not metadata such as the transaction journal) to the FastStart area, which is represented on disk as the SYSDBIMFS_LOBSEG$ segment. The database stores the FastStart metadata in the SYSAUX tablespace. In an Oracle Real Application Clusters (Oracle RAC) environment, IM FastStart data is shared across all nodes.

> **Note:**
>
> IM FastStart is not supported in a standby database instance.

Whereas the initial loading of IMCUs into memory is expensive and CPU-bound, an IM FastStart tablespace requires intermittent I/O. The database periodically writes columnar data to the IM FastStart area. If a database instance must restart, then Oracle Database reads the columnar data directly from the IM FastStart area rather than reconstructing the IMCUs from scratch. No compression or formatting of the columnar data is required.

Examples

This example creates fs_tbs as an ASSM tablespace, and then uses FASTSTART_ENABLE to specify this tablespace as the IM FastStart area:

```
CREATE TABLESPACE fs_tbs
  DATAFILE 'fs_tbs.dbf' SIZE 500M
  EXTENT MANAGEMENT LOCAL
```

```
  SEGMENT SPACE MANAGEMENT AUTO;

EXEC DBMS_INMEMORY_ADMIN.FASTSTART_ENABLE('fs_tbs');
```

The following query shows that the IM FastStart LOB was created (sample output included):

```
COL OWNER FORMAT a5
COL SEGMENT_NAME FORMAT a20
SELECT   l.OWNER, l.SEGMENT_NAME, SUM(s.BYTES)/1024/1024 MB
FROM     DBA_LOBS l, DBA_SEGMENTS s
WHERE    l.SEGMENT_NAME = s.SEGMENT_NAME
AND      l.TABLESPACE_NAME = 'FS_TBS'
GROUP BY l.OWNER, l.SEGMENT_NAME;

OWNER SEGMENT_NAME         MB
----- -------------------- ----------
SYS   SYSDBIMFS_LOBSEG$    .125
```

96.4.5 FASTSTART_MIGRATE_STORAGE Procedure

This procedure moves the In-Memory FastStart (IM FastStart) data and catalogs from the current tablespace to a new tablespace.

Syntax

```
DBMS_INMEMORY_ADMIN.FASTSTART_MIGRATE_STORAGE(
   tbs_name    IN    VARCHAR2 );
```

Parameters

Table 96-3 FASTSTART_MIGRATE_STORAGE Procedure Parameters

Parameter	Description
tbs_name	The name of the new ASSM tablespace for the IM FastStart area.

Security Model

DBA privileges are required to execute this procedure.

Usage Notes

When you execute the procedure, the database executes the following actions:

1. Waits until all IM FastStart operations complete
2. Disables the IM FastStart feature
3. Copies IM FastStart data and metadata to the new tablespace, leaving the old tablespace intact
4. Re-enables IM FastStart the feature

Examples

The following program obtains the name of the IM FastStart tablespace, if one exists, and prints the result (sample output included):

```
VARIABLE b_fstbs VARCHAR2(20)
BEGIN
   :b_fstbs := DBMS_INMEMORY_ADMIN.GET_FASTSTART_TABLESPACE;
END;
/
PRINT b_fstbs

B_FSTBS
------------------------------
FS_TBS
```

The following statements create a new tablespace named `fs_tbs2`, and then migrate the IM FastStart area to this tablespace:

```
CREATE TABLESPACE fs_tbs2
  DATAFILE 'fs_tbs2.dbf' SIZE 500M
  EXTENT MANAGEMENT LOCAL
  SEGMENT SPACE MANAGEMENT AUTO;

EXEC DBMS_INMEMORY_ADMIN.FASTSTART_MIGRATE_STORAGE('fs_tbs2');
```

The following program prints the name of the current IM FastStart tablespace (sample output included):

```
BEGIN
   :b_fstbs := DBMS_INMEMORY_ADMIN.GET_FASTSTART_TABLESPACE;
END;
/
PRINT b_fstbs

B_FSTBS
------------------------------
FS_TBS2
```

96.4.6 GET_FASTSTART_TABLESPACE Function

This function returns the tablespace assigned to In-Memory FastStart (IM FastStart). If the feature is disabled, then the function returns `NOT ENABLED`.

Syntax

```
DBMS_INMEMORY_ADMIN.GET_FASTSTART_TABLESPACE();
```

Security Model

DBA privileges are required to execute this function.

Examples

This program obtains the name of the IM FastStart tablespace, if one exists, and prints the result:

```
VARIABLE b_fstbs VARCHAR2(20)
BEGIN
   :b_fstbs := DBMS_INMEMORY_ADMIN.GET_FASTSTART_TABLESPACE;
END;
/
PRINT b_fstbs

B_FSTBS
------------------------------
NOT ENABLED
```

96.4.7 IME_CAPTURE_EXPRESSIONS Procedure

This procedure captures the 20 most frequently accessed (“hottest”) expressions in the database in the specified time interval.

Syntax

```
DBMS_INMEMORY_ADMIN.IME_CAPTURE_EXPRESSIONS(
   snapshot    IN    VARCHAR2);
```

Parameters

Table 96-4 IME_CAPTURE_EXPRESSIONS Procedure Parameters

Parameter	Description
`snapshot`	Specifies a snapshot that defines the time interval in which expression statistics are considered. You can specify any of the following values: • `CUMULATIVE` The database considers all expression statistics since the creation of the database. • `CURRENT` The database considers only expression statistics from the past 24 hours. • `WINDOW` The database considers statistics for expressions tracked in the most recent expression capture window. The database adds hidden virtual columns for expressions tracked in the most recent window. If the capture window is currently open, then the database considers all expressions tracked in the current window up until this point, and then materializes the hottest expressions. To list the expressions that have been tracked in the current window, query `DBA_EXPRESSION_STATISTICS` with `SNAPSHOT='WINDOW'`.

Usage Notes

When you invoke this procedure, the database queries the Expression Statistics Store (ESS), and considers only expressions on tables that are at least partially populated in the IM column store. The database adds the 20 hottest expressions to their respective tables as hidden virtual columns, prefixed with the string `SYS_IME`, and applies the default `INMEMORY` column compression clause. If any `SYS_IME` columns added during a previous invocation are no longer in the latest top 20 list, then the database marks them as `NO INMEMORY`.

> **Note:**
>
> Executing the `IME_CAPTURE_EXPRESSIONS` procedure on a standby database has no effect.

The maximum number of `SYS_IME` columns for a table, regardless of whether the attribute is `INMEMORY` or `NO INMEMORY`, is 50. After the limit is reached for a table, the database will not add new `SYS_IME` columns. To make space for new expressions, you must manually drop `SYS_IME` columns with the IME_DROP_ALL_EXPRESSIONS Procedure or IME_DROP_EXPRESSIONS Procedure.

The 50-expression limit for each table, which includes both `INMEMORY` and `NO INMEMORY` expressions, is different from the 20-expression limit for the database, which includes only `INMEMORY` expressions. For example, if 20 tables are populated in the IM column store, then each table might each have 1 `SYS_IME` column with the `INMEMORY` attribute, and 49 `SYS_IME` columns with the `NO INMEMORY` attribute.

IM expressions and virtual columns are stored in In-Memory structured called In-Memory Expression Units (IMEUs). Every IMEU is linked to a parent In-Memory Compression Unit (IMCU) from which it inherits compression characteristics.

ESS information is stored in the data dictionary and exposed in the `DBA_EXPRESSION_STATISTICS` view. This view shows the metadata that the optimizer has collected in the ESS. IM expressions are exposed as system-generated virtual columns, prefixed by the string `SYS_IME`, in the `DBA_IM_EXPRESSIONS` view.

Example 96-3 Capturing Expressions in a User-Defined Window

This example demonstrates use of the `WINDOW` capture mode. Your goal is to open and close an expression capture window, and then capture all expressions that the database tracked during this window. You perform the following steps:

1. Open an expression capture window, generate expressions, and then close the window:

```
EXEC DBMS_INMEMORY_ADMIN.IME_OPEN_CAPTURE_WINDOW();
-- Generate expressions for the database to track
EXEC DBMS_INMEMORY_ADMIN.IME_CLOSE_CAPTURE_WINDOW();
```

2. Query `DBA_EXPRESSION_STATICS` (sample output included):

```
COL OWNER FORMAT A6
COL TABLE_NAME FORMAT A9
```

```
COL COUNT FORMAT 99999
COL CREATED FORMAT A10
COL EXPRESSION_TEXT FORMAT A29

SELECT OWNER, TABLE_NAME, EVALUATION_COUNT AS COUNT,
       CREATED, EXPRESSION_TEXT
FROM   DBA_EXPRESSION_STATISTICS
WHERE  SNAPSHOT = 'WINDOW'
AND    OWNER = 'SH';

OWNER  TABLE_NAM  COUNT CREATED    EXPRESSION_TEXT
------ --------- ------ ---------- ------------------------
SH     SALES       4702 09-OCT-17  "QUANTITY_SOLD"
SH     SALES       4702 09-OCT-17  "QUANTITY_SOLD"*"AMOUNT_SOLD"
SH     SALES       4702 09-OCT-17  "PROD_ID"
SH     SALES       4702 09-OCT-17  "CUST_ID"
SH     SALES       4702 09-OCT-17  "CHANNEL_ID"
SH     SALES       4702 09-OCT-17  "AMOUNT_SOLD"
```

The preceding query shows both the columns tracked in the ESS and the expressions captured during the window for queries in the `sh` schema. During the most recent window, the database captured one expression: `QUANTITY_SOLD*AMOUNT_SOLD`.

3. Use `IME_CAPTURE_EXPRESSIONS` to make the database consider all expressions in the current window for materialization:

```
EXEC DBMS_INMEMORY_ADMIN.IME_CAPTURE_EXPRESSIONS('WINDOW');
```

4. Query `DBA_IM_EXPRESSIONS` (sample output included):

```
COL OWNER FORMAT a6
COL TABLE_NAME FORMAT a9
COL COLUMN_NAME FORMAT a25
SET LONG 50
SET LINESIZE 150

SELECT OWNER, TABLE_NAME, COLUMN_NAME, SQL_EXPRESSION
FROM   DBA_IM_EXPRESSIONS;

OWNER  TABLE_NAM COLUMN_NAME               SQL_EXPRESSION
------ --------- ------------------------- ----------------------------
SH     SALES     SYS_IME000100000025201B   "QUANTITY_SOLD"*"AMOUNT_SOLD"
```

The preceding output shows all virtual columns that were added to the table and marked `INMEMORY` as part of the latest `IME_CAPTURE_EXPRESSIONS` invocation. The database gradually populates the captured expressions into the IM column store when it repopulates different IMCUs of the table.

5. Execute the following procedure to explicitly force a population of all captured IM expressions:

```
EXEC DBMS_INMEMORY_ADMIN.IME_POPULATE_EXPRESSIONS();
```

Note that you can populate IM expressions from a specific table by executing the `DBMS_INMEMORY.REPOPULATE` procedure with the `force` parameter set to `TRUE`.

Example 96-4 Capturing Expressions for the Past Day

The following program captures expressions tracked during the last 24 hours:

```
EXEC DBMS_INMEMORY_ADMIN.IME_CAPTURE_EXPRESSIONS('CURRENT');
```

96.4.8 IME_CLOSE_CAPTURE_WINDOW Procedure

This procedure signals the end of the current expression capture window.

Syntax

```
DBMS_INMEMORY_ADMIN.IME_CLOSE_CAPTURE_WINDOW();
```

Usage Notes

On invocation of this procedure, the optimizer saves all gathered statistics to disk, and essentially freezes the expressions tracked in the window. The database preserves the statistics captured in this window until a new expression capture window is opened, at which point the database purges the statistics captured in the previous window.

Example 96-5 Example

This example opens an expression capture window, and then issues `IME_CAPTURE_EXPRESSIONS('WINDOW')` so that the database considers all expressions in the current window for materialization. Finally, the example closes the window.

```
EXEC DBMS_INMEMORY_ADMIN.IME_OPEN_CAPTURE_WINDOW();
-- Generate expressions so that the database can track them
EXEC DBMS_INMEMORY_ADMIN.IME_CLOSE_CAPTURE_WINDOW();
EXEC DBMS_INMEMORY_ADMIN.IME_CAPTURE_EXPRESSIONS('WINDOW');
```

96.4.9 IME_DROP_ALL_EXPRESSIONS Procedure

This procedure drops all `SYS_IME` expression virtual columns in the database.

Syntax

```
DBMS_INMEMORY_ADMIN.IME_DROP_ALL_EXPRESSIONS();
```

Usage Notes

The `IME_DROP_ALL_EXPRESSIONS` procedure drops all `SYS_IME` columns from all tables, regardless of whether they have the `INMEMORY` attribute. In effect, the procedure acts as a database-wide reset button.

Using `IME_DROP_ALL_EXPRESSIONS` triggers a drop of all IMEUs *and* IMCUs for segments that have `SYS_IME` columns. For example, if 50 populated tables have one `SYS_IME` column each, then `IME_DROP_ALL_EXPRESSIONS` removes all 50 tables from the IM column store. To populate these segments again, you must use the `DBMS_INMEMORY.POPULATE` procedure or perform a full table scan.

96.4.10 IME_GET_CAPTURE_STATE Procedure

This procedure returns the current capture state of the expression capture window and the timestamp of the most recent modification.

Syntax

```
DBMS_INMEMORY_ADMIN.IME_GET_CAPTURE_STATE(
   p_capture_state  OUT  VARCHAR2,
   p_last_modified  OUT  TIMESTAMP);
```

Parameters

Parameter	Description
p_capture_state	Describes the current state of the expression capture window. The following states are possible: • OPEN — Indicates that the window is open. • CLOSED — Indicates that the window is closed. • DEFAULT — Indicates that the window has not been used. It is equivalent to the CLOSED state.
p_last_modified	Indicates the timestamp of the most recent action.

Usage Notes

This procedure is useful for avoiding conflicting calls for IME_OPEN_CAPTURE_WINDOW Procedure and IME_CLOSE_CAPTURE_WINDOW Procedure. For example, if the current expression capture window state is OPEN, then you cannot open another window, and if the window state is CLOSED, then you cannot close a window.

Example 96-6 Determining the State of an Expression Capture Window

This example opens an expression capture window, and then determines its capture state.

```
EXEC DBMS_INMEMORY_ADMIN.IME_OPEN_CAPTURE_WINDOW();

VARIABLE b_state VARCHAR2(25)
VARIABLE b_time  VARCHAR2(10)
EXECUTE DBMS_INMEMORY_ADMIN.IME_GET_CAPTURE_STATE(:b_state, :b_time)
PRINT b_state b_time
```

The following sample output indicates that an expression capture window is currently open:

```
B_STATE
--------------------------------------------------
OPEN

B_TIME
--------------------------------------------------
09-OCT-17
```

96.4.11 IME_OPEN_CAPTURE_WINDOW Procedure

This procedure signals the beginning of an expression capture window.

Syntax

```
DBMS_INMEMORY_ADMIN.IME_OPEN_CAPTURE_WINDOW();
```

Security Model

Administrator privileges are required to execute this procedure.

Usage Notes

On invocation of this procedure, the optimizer begins a new window snapshot and starts tracking expressions that occur within this window. An expression capture window is global across all instances in an Oracle RAC database.

Conflicting actions are not permitted. For example, in an Oracle RAC database, opening expression capture window on instance 1 at time t0 and attempting to open another expression capture window on instance 2 at time t1 before closing the first window is a conflicting action. To obtain the current capture state and reduce the potential for conflicting procedure invocations, use the IME_GET_CAPTURE_STATE Procedure.

Example

This following program opens an expression capture window:

```
EXEC DBMS_INMEMORY_ADMIN.IME_OPEN_CAPTURE_WINDOW();
```

96.4.12 IME_POPULATE_EXPRESSIONS Procedure

This procedure forces the population of expressions captured in the latest invocation of `DBMS_INMEMORY_ADMIN.IME_CAPTURE_EXPRESSIONS`.

Syntax

```
DBMS_INMEMORY_ADMIN.IME_POPULATE_EXPRESSIONS();
```

Usage Notes

If you do not invoke this procedure, then the database gradually repopulates `SYS_IME` columns when their parent IMCUs are repopulated. If a table is not repopulated, then any new `SYS_IME` columns captured by the `IME_CAPTURE_EXPRESSIONS` procedure are not populated. `IME_POPULATE_EXPRESSIONS` solves this problem by forcing population.

Internally, the procedure invokes `DBMS_INMEMORY.REPOPULATE` for all tables that have `SYS_IME` columns with the `INMEMORY` attribute. To populate `SYS_IME` columns in a specified subset of tables, use `DBMS_INMEMORY.REPOPULATE` instead of `IME_POPULATE_EXPRESSIONS`.

96.4.13 POPULATE_WAIT Function

This function initiates population of all INMEMORY objects that have a priority greater than or equal to the specified priority, and returns a status value for the population. A user-specified interval specifies the maximum time that the function waits before returning the value to the caller.

Syntax

```
DBMS_INMEMORY_ADMIN.POPULATE_WAIT(
   priority    IN    VARCHAR2 DEFAULT 'LOW',
   percentage  IN    NUMBER   DEFAULT 100,
   timeout     IN    NUMBER   DEFAULT 99999999,
   force       IN    VARCHAR2 DEFAULT FALSE)
RETURN VARCHAR2;
```

Parameters

Table 96-5 POPULATE_WAIT Function Parameters

Parameter	Description
priority	Specifies that the database populate all INMEMORY objects with the specified priority setting or higher. The default priority is LOW. NONE is considered lowest priority. If you set to priority to NONE, then this function waits for all INMEMORY objects to populate.
percentage	Specifies the percentage of population required for the function to consider population to be complete. The default is 100. For example, if percentage is 50 and priority is NONE, and if 50% of the INMEMORY objects are populated in the IM column store, then the function returns the value 0 (population successful).
timeout	Specifies the number of seconds that must pass before the function returns -1, which indicates that the populate operation timed out. The default is 99999999 seconds, which is 115.74 days. Assume that timeout is 600, priority is LOW, and percentage is 100. If 10 minutes pass, but all PRIORITY LOW objects are not yet fully populated, then the function returns -1.
force	Specifies that the database should drop all INMEMORY segments that have a priority greater than or equal than the specified priority, and then repopulate these segments. The default is FALSE. Assume that the INMEMORY attribute applies to the sales table, which is partitioned. Only half the sales partitions are currently populated in the IM column store. If you execute POPULATE_WAIT with force set to TRUE, then the database drops all sales segments, and then repopulates them.

Return Values

The following table describes the possible return values for POPULATE_WAIT. The function returns the values 0, 1, 2, and 3 only if the condition is met before the end of the interval specified by timeout. For example, if timeout is 600, then the function returns 1 only if an out-of-memory error occurs before 600 seconds pass. The function returns -1 only if the end of the timeout interval occurs *before* the database completes the requested operation.

Table 96-6 Return Values for POPULATE_WAIT

Constant	Value	Description
POPULATE_TIMEOUT	-1	The function timed out while waiting for population to complete. Existing population jobs continue running in the background after -1 is returned. Reissuing POPULATE_TIMEOUT after -1 is returned reinitiates population; segments that are already populated are not dropped.
POPULATE_SUCCESS	0	All objects that met the priority criteria were populated to the specified percentage of completion.
POPULATE_OUT_OF_MEMORY	1	The In-Memory pool had insufficient memory to populate the objects that met the priority criteria to the specified percentage of completion.
POPULATE_NO_INMEMORY_OBJECTS	2	No INMEMORY objects met the specified priority criteria.
POPULATE_INMEMORY_SIZE_ZERO	3	The In-Memory column store is not enabled.

Usage Notes

Sample use cases for ensuring that objects are populated include:

- When the database is closed, open the database with STARTUP RESTRICT so that only administrators can access the database, and then execute POPULATE_WAIT with the desired timeout setting. If POPULATE_WAIT returns -1, indicating a timeout, then reexecute POPULATE_WAIT. When the function returns 0, disable the restricted session so that non-administrative users can query the database.
- Block database connections by using services or an application tier technique. When no analytic indexes exists, and when the application depends on the IM column store to provide reasonable performance, these techniques prevent runaway queries.

Example 96-7 Specifying a Timeout Interval for In-Memory Population

In this example, the database contains a number of In-Memory tables with a variety of priority settings. Your goal is to populate *every* In-Memory table to 100% completion in a restricted database session, and then disable the restricted session so that the application can be guaranteed of querying only the In-Memory representations.

Assume that the database is shut down. In SQL*Plus, you connect to an idle instance as SYSDBA, and then execute the following command (sample output included):

```
SQL> STARTUP RESTRICT
ORACLE instance started.

Total System Global Area 1157624280 bytes
Fixed Size                  8839640 bytes
```

```
Variable Size             754974720 bytes
Database Buffers           16777216 bytes
Redo Buffers                7933952 bytes
In-Memory Area            369098752 bytes
Database mounted.
Database opened.
```

The database is open, but is accessible only to administrative users. You execute the following statements in SQL*Plus (sample output shown in bold):

```
VARIABLE b_pop_status NUMBER

SELECT DBMS_INMEMORY_ADMIN.POPULATE_WAIT(
         priority   => 'NONE' ,
         percentage => 100    ,
         timeout    => 300    )
  INTO b_pop_status
FROM   DUAL;

PRINT b_pop_status
-1
```

After 5 minutes, the function returns the number `-1`. This code indicates that the function timed out while waiting for population to complete. 5 minutes is not long enough to populate all `INMEMORY` tables. You re-execute the `SELECT` statement, specifying a 30-minute timeout:

```
SELECT DBMS_INMEMORY_ADMIN.POPULATE_WAIT(
         priority   => 'NONE' ,
         percentage => 100    ,
         timeout    => 1800   )
  INTO b_pop_status
FROM   DUAL;

PRINT b_pop_status
0
```

After 8 minutes, the function returns the number `0`. This code indicates that all tables are completely populated. You now disable the restricted session so that the application can start query In-Memory objects with full confidence that only In-Memory representations will be accessed:

```
ALTER SYSTEM DISABLE RESTRICTED SESSION;
```

97
DBMS_IOT

The DBMS_IOT package creates a table into which references to the chained rows for an index-organized table can be placed using the ANALYZE command. DBMS_IOT can also create an exception table into which references to the rows of an index-organized table that violate a constraint can be placed during the enable_constraint operation.

DBMS_IOT is not loaded during database installation. To install DBMS_IOT, run dbmsiotc.sql, available in the ADMIN directory.

This chapter contains the following topics:

- Summary of DBMS_IOT Subprograms

> **Note:**
>
> With the introduction of logical-rowids for IOTs with Oracle Database Release 8.1, you no longer need to use the procedures contained in this package which is retained for backward compatibility only. It is however required for servers running with Oracle Database Release 8.0.

97.1 Summary of DBMS_IOT Subprograms

This table lists and briefly describes the DBMS_IOT subprograms.

Table 97-1 ***DBMS_IOT Package Subprograms***

Subprogram	Description
BUILD_CHAIN_ROWS_TABLE Procedure	Creates a table into which references to the chained rows for an index-organized table can be placed using the ANALYZE command
BUILD_EXCEPTIONS_TABLE Procedure	Creates an exception table into which rows of an index-organized table that violate a constraint can be placed

97.1.1 BUILD_CHAIN_ROWS_TABLE Procedure

This procedure creates a table into which references to the chained rows for an index-organized table can be placed using the ANALYZE command.

Syntax

```
DBMS_IOT.BUILD_CHAIN_ROWS_TABLE (
   owner               IN VARCHAR2,
   iot_name            IN VARCHAR2,
   chainrow_table_name IN VARCHAR2 default 'IOT_CHAINED_ROWS');
```

Parameters

Table 97-2 BUILD_CHAIN_ROWS_TABLE Procedure Parameters

Parameter	Description
owner	Owner of the index-organized table.
iot_name	Index-organized table name.
chainrow_table_name	Intended name for the chained-rows table.

Usage Notes

You should create a separate chained-rows table for each index-organized table to accommodate its primary key.

Examples

```
CREATE TABLE l(a char(16),b char(16), c char(16), d char(240),
PRIMARY KEY(a,b,c)) ORGANIZATION INDEX pctthreshold 10 overflow;
EXECUTE DBMS_IOT.BUILD_CHAIN_ROWS_TABLE('SYS','L','LC');
```

A chained-row table is created with the following columns:

```
Column Name                    Null?    Type
------------------------------ -------- ----
OWNER_NAME                              VARCHAR2(30)
TABLE_NAME                              VARCHAR2(30)
CLUSTER_NAME                            VARCHAR2(30)
PARTITION_NAME                          VARCHAR2(30)
SUBPARTITION_NAME                       VARCHAR2(30)
HEAD_ROWID                              ROWID
TIMESTAMP                               DATE
A                                       CHAR(16)
B                                       CHAR(16)
C                                       CHAR(16)
```

97.1.2 BUILD_EXCEPTIONS_TABLE Procedure

This procedure creates an exception table.

Rows of an index-organized table that violate a constraint can be placed into this table during the execution of the following SQL statements:

- ALTER TABLE ... ENABLE CONSTRAINT ... EXCEPTIONS INTO
- ALTER TABLE ... ADD CONSTRAINT ... EXCEPTIONS INTO

Syntax

```
DBMS_IOT.BUILD_EXCEPTIONS_TABLE (
   owner                IN VARCHAR2,
   iot_name             IN VARCHAR2,
   exceptions_table_name IN VARCHAR2 default 'IOT_EXCEPTIONS');
```

Parameters

Table 97-3 BUILD_EXCEPTIONS_TABLE Procedure Parameters

Parameter	Description
owner	Owner of the index-organized table.
iot_name	Index-organized table name.
exceptions_table_name	Intended name for exception-table.

Usage Notes

You should create a separate exception table for each index-organized table to accommodate its primary key.

Examples

```
EXECUTE DBMS_IOT.BUILD_EXCEPTIONS_TABLE('SYS','L','LE');
```

An exception table for the preceding index-organized table with the following columns:

```
Column Name                    Null?    Type
------------------------------ -------- ----
ROW_ID                                  VARCHAR2(30)
OWNER                                   VARCHAR2(30)
TABLE_NAME                              VARCHAR2(30)
CONSTRAINT                              VARCHAR2(30)
A                                       CHAR(16)
B                                       CHAR(16)
C                                       CHAR(16)
```

98
DBMS_JAVA

The DBMS_JAVA package provides a PL/SQL interface for accessing database functionality from Java.

For a complete description of this package within the context of DBMS_JAVA, see DBMS_JAVA in the *Oracle Database Java Developer's Guide*

99
DBMS_JOB

The DBMS_JOB package schedules and manages jobs in the job queue.

> **Note:**
>
> The DBMS_JOB package has been superseded by the DBMS_SCHEDULER package, and support for DBMS_JOB might be removed in future releases of Oracle Database. In particular, if you are administering jobs to manage system load, you are encouraged to disable DBMS_JOB by revoking the package execution privilege for users.
>
> For more information, see DBMS_SCHEDULER and "Moving from DBMS_JOB to DBMS_SCHEDULER" in the *Oracle Database Administrator's Guide*.

This chapter contains the following topics:

- Security Model
- Operational Notes
- Summary of DBMS_JOB Subprograms

99.1 DBMS_JOB Security Model

DBMS_JOB uses the same security policies as DBMS_SCHEDULER. You must have the CREATE JOB privilege to use DBMS_JOB.

Jobs cannot be altered or deleted other than jobs owned by the user. This is true for all users including those users granted DBA privileges.

You can execute procedures that are owned by the user for which the user is explicitly granted EXECUTE. However, procedures for which the user is granted the execute privilege through roles cannot be executed.

Note that, once a job is started and running, there is no easy way to stop the job.

99.2 DBMS_JOB Operational Notes

These notes describe stopping a job, and working with Oracle Real Application Clusters.

Stopping a Job

Note that, once a job is started and running, there is no easy way to stop the job.

Working with Oracle Real Application Clusters

DBMS_JOB supports multi-instance execution of jobs. By default jobs can be executed on any instance, but only one single instance will execute the job. In addition, you can force instance

binding by binding the job to a particular instance. You implement instance binding by specifying an instance number to the instance affinity parameter. Note, however, that in Oracle Database 10g Release 1 (10.1) instance binding is not recommended. Service affinity is preferred. This concept is implemented in the DBMS_SCHEDULER package.

The following procedures can be used to create, alter or run jobs with instance affinity. Note that not specifying affinity means any instance can run the job.

- DBMS_JOB.SUBMIT
- DBMS_JOB.INSTANCE
- DBMS_JOB.CHANGE
- DBMS_JOB.RUN

DBMS_JOB.SUBMIT

To submit a job to the job queue, use the following syntax:

```
DBMS_JOB.SUBMIT(
   job       OUT    BINARY_INTEGER,
   what      IN     VARCHAR2,
   next_date IN     DATE DEFAULT SYSDATE,
   interval  IN     VARCHAR2 DEFAULT 'NULL',
   no_parse  IN     BOOLEAN DEFAULT FALSE,
   instance  IN     BINARY_INTEGER DEFAULT ANY_INSTANCE,
   force     IN     BOOLEAN DEFAULT FALSE);
```

Use the parameters `instance` and `force` to control job and instance affinity. The default value of `instance` is 0 (zero) to indicate that any instance can execute the job. To run the job on a certain instance, specify the `instance` value. Oracle displays error `ORA-23319` if the `instance` value is a negative number or `NULL`.

The `force` parameter defaults to `false`. If `force` is `TRUE`, any positive integer is acceptable as the job instance. If `force` is `FALSE`, the specified instance must be running, or Oracle displays error number `ORA-23428`.

DBMS_JOB.INSTANCE

To assign a particular instance to execute a job, use the following syntax:

```
DBMS_JOB.INSTANCE(  JOB IN BINARY_INTEGER,
  instance                IN BINARY_INTEGER,
  force                   IN BOOLEAN DEFAULT FALSE);
```

The `FORCE` parameter in this example defaults to `FALSE`. If the instance value is 0 (zero), job affinity is altered and any available instance can execute the job despite the value of force. If the `INSTANCE` value is positive and the `FORCE` parameter is `FALSE`, job affinity is altered only if the specified instance is running, or Oracle displays error `ORA-23428`.

If the `force` parameter is `TRUE`, any positive integer is acceptable as the job instance and the job affinity is altered. Oracle displays error ORA-23319 if the `instance` value is negative or `NULL`.

DBMS_JOB.CHANGE

To alter user-definable parameters associated with a job, use the following syntax:

```
DBMS_JOB.CHANGE(  JOB IN BINARY_INTEGER,
what                  IN VARCHAR2 DEFAULT NULL,
next_date             IN DATE DEFAULT NULL,
interval              IN VARCHAR2 DEFAULT NULL,
instance              IN BINARY_INTEGER DEFAULT NULL,
force                 IN BOOLEAN DEFAULT FALSE );
```

Two parameters, `instance` and `force`, appear in this example. The default value of `instance` is `null` indicating that job affinity will not change.

The default value of `force` is `FALSE`. Oracle displays error `ORA-23428` if the specified instance is not running and error `ORA-23319` if the `instance` number is negative.

DBMS_JOB.RUN

The `force` parameter for `DBMS_JOB.RUN` defaults to `FALSE`. If `force` is `TRUE`, instance affinity is irrelevant for running jobs in the foreground process. If force is `FALSE`, the job can run in the foreground only in the specified instance. Oracle displays error `ORA-23428` if force is `FALSE` and the connected instance is the incorrect instance.

```
DBMS_JOB.RUN(
   job    IN BINARY_INTEGER,
   force  IN BOOLEAN DEFAULT FALSE);
```

99.3 Summary of DBMS_JOB Subprograms

This table lists the `DBMS_JOB` subprograms and briefly describes them.

Table 99-1 DBMS_JOB Package Subprograms

Subprogram	Description
BROKEN Procedure	Disables job execution
CHANGE Procedure	Alters any of the user-definable parameters associated with a job
INSTANCE Procedure	Assigns a job to be run by a instance
INTERVAL Procedure	Alters the interval between executions for a specified job
NEXT_DATE Procedure	Alters the next execution time for a specified job
REMOVE Procedure	Removes specified job from the job queue
RUN Procedure	Forces a specified job to run
SUBMIT Procedure	Submits a new job to the job queue
USER_EXPORT Procedures	Re-creates a given job for export, or re-creates a given job for export with instance affinity
WHAT Procedure	Alters the job description for a specified job

99.3.1 BROKEN Procedure

This procedure sets the broken flag. Broken jobs are never run.

Syntax

```
DBMS_JOB.BROKEN (
   job       IN  BINARY_INTEGER,
   broken    IN  BOOLEAN,
   next_date IN  DATE DEFAULT SYSDATE);
```

Parameters

Table 99-2 BROKEN Procedure Parameters

Parameter	Description
job	System-assigned ID of the job being run. To find this ID, query the JOB column of the USER_JOBS or DBA_JOBS view.
broken	Sets the job as broken or not broken. TRUE sets it as broken; FALSE sets it as not broken.
next_date	Next date when the job will be run.

> **Note:**
>
> If you set job as broken while it is running, Oracle resets the job's status to normal after the job completes. Therefore, only execute this procedure for jobs that are not running.

Usage Notes

- Your job will not be available for processing by the job queue in the background until it is committed.
- If a job fails 16 times in a row, Oracle automatically sets it as broken and then stops trying to run it.

99.3.2 CHANGE Procedure

This procedure changes any of the fields a user can set in a job.

Syntax

```
DBMS_JOB.CHANGE (
   job       IN  BINARY_INTEGER,
   what      IN  VARCHAR2,
   next_date IN  DATE,
   interval  IN  VARCHAR2,
   instance  IN  BINARY_INTEGER DEFAULT NULL,
   force     IN  BOOLEAN DEFAULT FALSE);
```

Parameters

Table 99-3 CHANGE Procedure Parameters

Parameter	Description
job	System-assigned ID of the job being run. To find this ID, query the JOB column of the USER_JOBS or DBA_JOBS view.
what	PL/SQL procedure to run.
next_date	Next date when the job will be run.

Table 99-3 (Cont.) CHANGE Procedure Parameters

Parameter	Description
interval	Date function; evaluated immediately before the job starts running.
instance	When a job is submitted, specifies which instance can run the job. This defaults to NULL, which indicates that instance affinity is not changed.
force	If this is FALSE, then the specified instance (to which the instance number change) must be running. Otherwise, the routine raises an exception. If this is TRUE, then any positive integer is acceptable as the job instance.

Usage Notes

- Your job will not be available for processing by the job queue in the background until it is committed.
- The parameters instance and force are added for job queue affinity. Job queue affinity gives users the ability to indicate whether a particular instance or any instance can run a submitted job.
- If the parameters what, next_date, or interval are NULL, then leave that value as it is.

Example

```
BEGIN
   DBMS_JOB.CHANGE(14144, null, null, 'sysdate+3');
   COMMIT;
END;
```

99.3.3 INSTANCE Procedure

This procedure changes job instance affinity.

Syntax

```
DBMS_JOB.INSTANCE (
   job         IN BINARY_INTEGER,
   instance    IN BINARY_INTEGER,
   force       IN BOOLEAN DEFAULT FALSE);
```

Parameters

Table 99-4 INSTANCE Procedure Parameters

Parameter	Description
job	System-assigned ID of the job being run. To find this ID, query the JOB column of the USER_JOBS or DBA_JOBS view.
instance	When a job is submitted, a user can specify which instance can run the job.

Table 99-4 (Cont.) INSTANCE Procedure Parameters

Parameter	Description
force	If this is TRUE, then any positive integer is acceptable as the job instance. If this is FALSE (the default), then the specified instance must be running; otherwise the routine raises an exception.

Usage Notes

Your job will not be available for processing by the job queue in the background until it is committed.

99.3.4 INTERVAL Procedure

This procedure changes how often a job runs.

Syntax

```
DBMS_JOB.INTERVAL (
   job       IN  BINARY_INTEGER,
   interval  IN  VARCHAR2);
```

Parameters

Table 99-5 INTERVAL Procedure Parameters

Parameter	Description
job	System-assigned ID of the job being run. To find this ID, query the JOB column of the USER_JOBS or DBA_JOBS view.
interval	Date function, evaluated immediately before the job starts running.

Usage Notes

- If the job completes successfully, then this new date is placed in next_date. interval is evaluated by plugging it into the statement select interval into next_date from dual;
- The interval parameter must evaluate to a time in the future. Legal intervals include:

Interval	Description
'sysdate + 7'	Run once a week.
'next_day(sysdate,''TUESDAY'')'	Run once every Tuesday.
'null'	Run only once.

- If interval evaluates to NULL and if a job completes successfully, then the job is automatically deleted from the queue.
- Your job will not be available for processing by the job queue in the background until it is committed.

99.3.5 NEXT_DATE Procedure

This procedure changes when an existing job next runs.

Syntax

```
DBMS_JOB.NEXT_DATE (
   job       IN  BINARY_INTEGER,
   next_date IN  DATE);
```

Parameters

Table 99-6 NEXT_DATE Procedure Parameters

Parameter	Description
job	System-assigned ID of the job being run. To find this ID, query the JOB column of the USER_JOBS or DBA_JOBS view.
next_date	Date of the next refresh: it is when the job will be automatically run, assuming there are background processes attempting to run it.

Usage Notes

Your job will not be available for processing by the job queue in the background until it is committed.

99.3.6 REMOVE Procedure

This procedure removes an existing job from the job queue. This currently does not stop a running job.

Syntax

```
DBMS_JOB.REMOVE (
   job       IN  BINARY_INTEGER );
```

Parameters

Table 99-7 REMOVE Procedure Parameters

Parameter	Description
job	System-assigned ID of the job being run. To find this ID, query the JOB column of the USER_JOBS or DBA_JOBS view.

Usage Notes

Your job will not be available for processing by the job queue in the background until it is committed.

Example

```
BEGIN
   DBMS_JOB.REMOVE(14144);
```

```
   COMMIT;
END;
```

99.3.7 RUN Procedure

This procedure runs job JOB now. It runs it even if it is broken.

Running the job recomputes next_date. See data dictionary view USER_JOBS or DBA_JOBS.

Syntax

```
DBMS_JOB.RUN (
   job       IN  BINARY_INTEGER,
   force     IN  BOOLEAN DEFAULT FALSE);
```

Parameters

Table 99-8 RUN Procedure Parameters

Parameter	Description
job	System-assigned ID of the job being run. To find this ID, query the JOB column of the USER_JOBS or DBA_JOBS view.
force	If this is TRUE, then instance affinity is irrelevant for running jobs in the foreground process. If this is FALSE, then the job can be run in the foreground only in the specified instance.

Example

```
EXECUTE DBMS_JOB.RUN(14144);
```

> **WARNING:**
>
> This re-initializes the current session's packages.

Exceptions

An exception is raised if force is FALSE, and if the connected instance is the wrong one.

99.3.8 SUBMIT Procedure

This procedure submits a new job. It chooses the job from the sequence sys.jobseq.

Syntax

```
DBMS_JOB.SUBMIT (
   job       OUT BINARY_INTEGER,
   what      IN  VARCHAR2,
   next_date IN  DATE DEFAULT SYSDATE,
   interval  IN  VARCHAR2 DEFAULT 'null',
   no_parse  IN  BOOLEAN DEFAULT FALSE,
```

```
   instance  IN  BINARY_INTEGER DEFAULT any_instance,
   force     IN  BOOLEAN DEFAULT FALSE);
```

Parameters

Table 99-9 SUBMIT Procedure Parameters

Parameter	Description
job	System-assigned ID of the job being run. To find this ID, query the JOB column of the USER_JOBS or DBA_JOBS view

what	PL/SQL text o the job to be run. This must be a valid PL/SQL statement or block of code. For example, to run a stored procedure P, you could pass the string P; (with the semi-colon) to this routine. The SQL that you submit in the what parameter is wrapped in the following PL/SQL block:
	`DECLARE`
	`job BINARY_INTEGER := :job;`
	`next_date DATE := :mydate;`
	`broken BOOLEAN := FALSE;`
	`BEGIN`
	`WHAT`
	`:mydate := next_date;`
	`IF broken THEN :b := 1; ELSE :b := 0; END IF;`
	`END;`
	Ensure that you include the ; semi-colon with the statement.

next_date	Next date when the job will be run.
interval	Date function that calculates the next time to run the job. The default is NULL. This must evaluate to a either a future point in time or NULL.
no_parse	A flag. The default is FALSE. If this is set to FALSE, then Oracle parses the procedure associated with the job. If this is set to TRUE, then Oracle parses the procedure associated with the job the first time that the job is run. For example, if you want to submit a job before you have created the tables associated with the job, then set this to TRUE.
instance	When a job is submitted, specifies which instance can run the job.
force	If this is TRUE, then any positive integer is acceptable as the job instance. If this is FALSE (the default), then the specified instance must be running; otherwise the routine raises an exception.

Usage Notes

- Your job will not be available for processing by the job queue in the background until it is committed.
- The parameters instance and force are added for job queue affinity. Job queue affinity gives users the ability to indicate whether a particular instance or any instance can run a submitted job.

Example

This submits a new job to the job queue. The job calls the procedure DBMS_DDL.ANALYZE_OBJECT to generate optimizer statistics for the table DQUON.ACCOUNTS. The

statistics are based on a sample of half the rows of the ACCOUNTS table. The job is run every 24 hours:

```
VARIABLE jobno number;
BEGIN
   DBMS_JOB.SUBMIT(:jobno,
      'dbms_ddl.analyze_object(''TABLE'',
      ''DQUON'', ''ACCOUNTS'',
      ''ESTIMATE'', NULL, 50);'
      SYSDATE, 'SYSDATE + 1');
   COMMIT;
END;
/
Statement processed.
print jobno
JOBNO
----------
14144
```

99.3.9 USER_EXPORT Procedures

There are two overloaded procedures. The first produces the text of a call to re-create the given job. The second alters instance affinity (8*i* and after) and preserves the compatibility.

Syntax

```
DBMS_JOB.USER_EXPORT (
   job    IN     BINARY_INTEGER,
   mycall IN OUT VARCHAR2);

DBMS_JOB.USER_EXPORT (
   job      IN     BINARY_INTEGER,
   mycall   IN OUT VARCHAR2,
   myinst   IN OUT VARCHAR2);
```

Parameters

Table 99-10 USER_EXPORT Procedure Parameter

Parameter	Description
job	System-assigned ID of the job being run. To find this ID, query the JOB column of the USER_JOBS or DBA_JOBS view.
mycall	Text of a call to re-create the given job.
myinst	Text of a call to alter instance affinity.

99.3.10 WHAT Procedure

This procedure changes what an existing job does, and replaces its environment.

Syntax

```
DBMS_JOB.WHAT (
   job       IN  BINARY_INTEGER,
   what      IN  VARCHAR2);
```

Parameters

Table 99-11 WHAT Procedure Parameters

Parameter	Description
`job`	System-assigned ID of the job being run. To find this ID, query the `JOB` column of the `USER_JOBS` or `DBA_JOBS` view.
`what`	PL/SQL procedure to run.

Usage Notes

- Your job will not be available for processing by the job queue in the background until it is committed.
- Some legal values of `what` (assuming the routines exist) are:
  - `'myproc(''10-JAN-82'', next_date, broken);'`
  - `'scott.emppackage.give_raise(''JENKINS'', 30000.00);'`
  - `'dbms_job.remove(job);'`

100
DBMS_JSON

The DBMS_JSON package provides an interface for data-guide operations.

This chapter contains the following topics:

- DBMS_JSON Overview
- DBMS_JSON Security Model
- DBMS_JSON Constants
- Summary of DBMS_JSON Subprograms

100.1 DBMS_JSON Overview

Package DBMS_JSON provides subprograms for manipulating JavaScript Object Notation (JSON) data that is stored in Oracle Database.

100.2 DBMS_JSON Security Model

PUBLIC is granted the EXECUTE privilege on package DBMS_JSON. Its subprograms execute with invoker's rights privileges.

100.3 DBMS_JSON Constants

The DBMS_JSON package uses these constants to define the JSON schema types and data-guide formatting options.

Table 100-1 DBMS_JSON Constants Defined for JSON Data-Guide Formatting

Name	Value	Description
FORMAT_FLAT	2	Display flat format
FORMAT_HIERARCHICAL	1	Display hierarchical format
PRETTY	1	Use appropriate indention to improve readability

Table 100-2 DBMS_JSON Constants for JSON Schema Types

Name	Type	Value	Description
TYPE_ARRAY	NUMBER(2)	6	A JSON array
TYPE_BOOLEAN	NUMBER(2)	2	A JSON boolean
TYPE_GEOJSON	NUMBER(2)	7	Geographic JSON data
TYPE_NULL	NUMBER(2)	1	The JSON NULL value
TYPE_NUMBER	NUMBER(2)	3	A JSON number
TYPE_OBJECT	NUMBER(2)	5	A JSON object

Table 100-2 (Cont.) DBMS_JSON Constants for JSON Schema Types

Name	Type	Value	Description
TYPE_STRING	NUMBER(2)	4	A JSON string
TYPE_BINARY	NUMBER(2)	17	Oracle extended JSON type binary
TYPE_DATE	NUMBER(2)	13	Oracle extended JSON type date
TYPE_DOUBLE	NUMBER(2)	12	Oracle extended JSON type double
TYPE_DSINTERVAL	NUMBER(2)	16	Oracle extended JSON type day-second interval
TYPE_FLOAT	NUMBER(2)	11	Oracle extended JSON type float
TYPE_TIMESTAMP	NUMBER(2)	14	Oracle extended JSON type timestamp
TYPE_YMINTERVAL	NUMBER(2)	15	Oracle extended JSON type year-month interval

Table 100-3 DBMS_JSON Constants for mvrefreshmode Parameter

Name	Type	Value	Description
MV_REFRESH_ON_STATEMENT	NUMBER(2)	1	Creates the materialized view with refresh on statement.
MV_REFRESH_ON_COMMIT	NUMBER(2)	2	Creates the materialized view with refresh on commit.
MV_REFRESH_ON_DEMAND	NUMBER(2)	3	Creates the materialized view with refresh on demand.

JSON Developer's Guide

100.4 Summary of DBMS_JSON Subprograms

This table lists the DBMS_JSON subprograms and briefly describes them.

DBMS_JSON Package Subprograms

Subprogram	Description
ADD_VIRTUAL_COLUMNS Procedure	Add virtual columns based on data-guide information. This has no effect when running on the shard catalog server — no virtual column is added.
CREATE_VIEW Procedure	Create a view with relational columns and scalar JSON fields as specified in a data guide.

Subprogram	Description
CREATE_VIEW_ON_PATH Procedure	Create a view based on data-guide information, with relational columns, top-level scalar types, and fully expanded sub-tree under a given path. When running on the shard catalog server this raises an error stating that the data guide is empty.
DROP_VIRTUAL_COLUMNS Procedure	Drop virtual columns created by procedure `add_virtual_columns`. This has no effect when running on the shard catalog server.
GET_INDEX_DATAGUIDE Function	Get JSON data guide from a data guide-enabled JSON search index. When running on the shard catalog server this returns a single empty row as result.
GET_VIEW_SQL Procedure	Add a description here.
RENAME_COLUMN Procedure	Set the preferred name for a view column or a virtual column creating using a data guide. This has no effect when running on the shard catalog server.

Note:

In the context of sharding, each individual shard maintains its own data-guide information, which is obtained from the JSON documents stored in that shard. When running on individual shard, procedures in this package that use data-guide information use only the information that is maintained for that shard.

100.4.1 ADD_VIRTUAL_COLUMNS Procedure

This procedure adds virtual columns based on the data guide.

The virtual column name is the value of `o:preferred_vc_name` in the data guide. The procedure ignores JSON objects, arrays, and fields under arrays in the data guide. Before it adds virtual columns, procedure `ADD_VIRTUAL_COLUMNS` first drops any existing virtual columns that were projected from fields in the same JSON column by a previous invocation of `ADD_VIRTUAL_COLUMNS` or by data-guide change-trigger procedure `add_vc` (in effect, it does what procedure `DBMS_JSON.DROP_VIRTUAL_COLUMNS` does).

See Also:

- DROP_VIRTUAL_COLUMNS Procedure
- *Oracle Database JSON Developer's Guide*

Syntax

```
DBMS_JSON.ADD_VIRTUAL_COLUMNS (
    tablename               IN  VARCHAR2,
    jcolname                IN  VARCHAR2,
    dataguide               IN  CLOB,
    resolvenameconflicts    IN  BOOLEAN  DEFAULT FALSE,
    colnameprefix           IN VARCHAR2  DEFAULT NULL,
    mixedcasecolumns        IN BOOLEAN   DEFAULT FALSE);
```

For the following signature you must have a data guide-enabled search index on the JSON column. This is not needed for the previous signature.

```
DBMS_JSON.ADD_VIRTUAL_COLUMNS (
    tablename  IN  VARCHAR2,
    jcolname   IN  VARCHAR2,
    frequency      NUMBER    DEFAULT 0,
    hidden         BOOLEAN   DEFAULT FALSE);
```

Parameters

Table 100-4 ADD_VIRTUAL_COLUMNS Procedure Parameters

Parameter	Description
`tablename`	Name of the table containing JSON column `jcolname`.
`jcolname`	Name of the JSON column in table `tablename` that contains the data from which to create the virtual column.
`dataguide`	The data guide. When `o:hidden` in the data guide for a particular JSON field is set to `TRUE`, the corresponding virtual column is added as a hidden column. The default value of `o:hidden` is `FALSE`.
`resolvenameconflicts`	By default, if there are any conflicts among `o:preferred_column_name`, an error is raised. By setting this parameter to `TRUE`, the procedure automatically resolves the virtual column name conflicts by appending a sequence number. The default value is `FALSE`.
`colnameprefix`	By default, the virtual column name is the same as the JSON field name. This parameter allows you to add a prefix to the virtual column names.
`mixedcasecolumns`	By default, the virtual column names are case sensitive. If this parameter value is set to `FALSE`, the virtual column names become non-case-sensitive.
`frequency`	Sets the minimum frequency threshold to display JSON columns. A frequency of 0 means display all JSON columns. Also, all JSON columns are displayed if statistics have not been collected, effectively overriding any value set by this parameter.
`hidden`	`TRUE` means the added virtual column is hidden; `FALSE` means it is not. The default is `FALSE`.

Usage Notes

Procedure `DBMS_STATS.GATHER_STATS` collects statistics in the data guide. If the frequency statistic has not been collected, frequency is `NULL`. Setting the frequency to a value greater than zero means do not include columns for which there are no frequency statistics collected (statistic is `NULL`), unless `DBMS_STATS.GATHER_STATS` has

never been executed. In that case, the frequency parameter is ignored and all columns are displayed in the view.

100.4.2 CREATE_VIEW Procedure

This procedure creates a view with relational columns, using scalar JSON fields as specified in the data guide. A data guide-enabled JSON search index is not required for this procedure; the data guide is passed to the procedure.

> **See Also:**
>
> *Oracle Database JSON Developer's Guide*

Syntax

```
PROCEDURE CREATE_VIEW (
   viewname                VARCHAR2,
   tablename               VARCHAR2,
   jcolname                VARCHAR2,
   dataguide               CLOB,
   resourcepath            VARCHAR2 DEFAULT NULL,
   materialize             BOOLEAN  DEFAULT FALSE,
   mvrefreshmode           NUMBER   DEFAULT MV_REFRESH_ON_STATEMENT,
   path                    VARCHAR2 DEFAULT '$',
   resolvenameconflicts    BOOLEAN  DEFAULT FALSE,
   colnameprefix           VARCHAR2 DEFAULT NULL,
   mixedcasecolumns        BOOLEAN DEFAULT FALSE);
```

Parameters

Table 100-5 DBMS_JSON.CREATE_VIEW Procedure Parameters

Parameter	Description
`viewname`	Name of the view.
`tablename`	Name of the table containing JSON column `jcolname`.
`jcolname`	Name of the JSON column in table `tablename` that is used to create the view.
`dataguide`	The data guide.
`resourcepath`	This parameter is for internal use. Value of this parameter is always `NULL`.
`materialize`	The value of this parameter is boolean and indicates if the view is materialized or not.
`mvrefreshmode`	When materialize is true, this parameter specifies the materialized view refresh mode. For more information on materialized view refresh mode options, see DBMS_JSON Constants.
`path`	The path of the `JSON` field to be expanded. It uses `JSON` path-expression syntax. It expands the descendants under the specified path, and creates view columns for each scalar value in the resulting sub-tree. The path `$` creates a view starting from the `JSON` document root.

Table 100-5 (Cont.) DBMS_JSON.CREATE_VIEW Procedure Parameters

Parameter	Description
`resolvenameconflicts`	By default, if there are any conflicts among `o:preferred_column_name`, an error is raised. By setting this parameter to `TRUE`, the procedure automatically resolves the virtual column name conflicts by appending a sequence number. The default value is `FALSE`.
`colnameprefix`	By default, the view column name is the same as the `JSON` field name. This parameter allows users to provide a prefix to prepend to the view column names.
`mixedcasecolumns`	By default, the view column names are case sensitive. You can use this parameter to change the case sensitivity behavior of the view column names.

100.4.3 CREATE_VIEW_ON_PATH Procedure

This procedure creates a view with relational columns, using top-level scalar values and the scalar values in the expanded sub-tree under a given path. The JSON column must have a data guide-enabled search index.

> **See Also:**
>
> *Oracle Database JSON Developer's Guide*

Syntax

```
PROCEDURE CREATE_VIEW_ON_PATH(
   viewname VARCHAR2,
   tablename VARCHAR2,
   jcolname VARCHAR2,
   path VARCHAR2,
   frequency NUMBER DEFAULT 0);
```

Parameters

Table 100-6 CREATE_VIEW_ON_PATH Procedure Parameters

Parameter	Description
`viewname`	Name of the view.
`tablename`	Name of the table containing JSON column `jcolname`.
`jcolname`	Name of the JSON column in table `tablename` that is used to create the view. The column must have a data guide-enabled JSON search index, or else an error is raised.
`path`	The path of the JSON field to be expanded. It uses JSON path-expression syntax. It expands the descendants under the specified path, and creates view columns for each scalar value in the resulting sub-tree. The path `$` creates a view starting from the JSON document root.

Table 100-6 (Cont.) CREATE_VIEW_ON_PATH Procedure Parameters

Parameter	Description
`frequency`	The minimum frequency threshold for displaying the JSON columns. A frequency of 0 means display all JSON columns. All JSON columns are also displayed if statistics have not been collected, effectively overriding any value set by this parameter. The view only displays JSON fields with frequency greater than the given `frequency`. It does not display JSON fields added after collecting statistics if the given frequency is greater than 0, if their statistic columns are `NULL`.

100.4.4 DROP_VIRTUAL_COLUMNS Procedure

Drop all virtual columns that were added using PL/SQL procedure `DBMS_JSON.add_virtual_columns` or using data-guide change-trigger procedure `add_vc`.

> **See Also:**
>
> - ADD_VIRTUAL_COLUMNS Procedure
> - *Oracle Database JSON Developer's Guide*

Syntax

```
PROCEDURE DROP_VIRTUAL_COLUMNS(
   tablename VARCHAR2,
   jcolname VARCHAR2);
```

Parameters

Table 100-7 DBMS_JSON.DROP_VIRTUAL_COLUMNS Procedure Parameters

Parameter	Description
`tablename`	Name of the table containing JSON column `jcolname`.
`jcolname`	Name of the JSON column in table `tablename`.

100.4.5 GET_INDEX_DATAGUIDE Function

`GET_INDEX_DATAGUIDE` gets JSON data guide from data guide-enabled JSON search index.

> **See Also:**
>
> *Oracle Database JSON Developer's Guide*

Syntax

```
FUNCTION GET_INDEX_DATAGUIDE(
   tablename VARCHAR2,
   jcolname VARCHAR2,
   format NUMBER,
   pretty NUMBER DEFAULT 0)
   RETURN CLOB;
```

Parameters

Table 100-8 DBMS_JSON.GET_INDEX_DATAGUIDE Procedure Parameters

Parameter	Description
`tablename`	Name of the table containing JSON column `jcolname`.
`jcolname`	Name of the JSON column in table `tablename` that has a data guide-enabled JSON search index.
`format`	The data-guide format: • `FORMAT_HIERARCHICAL` — hierarchical format • `FORMAT_FLAT` — flat format
`pretty`	A value of `DBMS_JSON.PRETTY` means pretty-print the data guide, using indention to improve readability.

Example 100-1 Example Get Data Guide in Hierarchical Pretty Format

This example returns the data guide in hierarchical format.

```
SELECT DBMS_JSON.GET_INDEX_DATAGUIDE('T1', 'PO',
DBMS_JSON.FORMAT_HIERARCHICAL, DBMS_JSON.PRETTY)
FROM DUAL;
```

100.4.6 GET_VIEW_SQL Procedure

This procedure returns the creating view DDL without actually creating the view. A data guide-enabled JSON search index is not required for this procedure; the data guide is passed to the procedure.

> **See Also:**
>
> *Oracle Database JSON Developer's Guide*

Syntax

```
PROCEDURE GET_VIEW_SQL (
   viewname                VARCHAR2,
   tablename               VARCHAR2,
   jcolname                VARCHAR2,
   dataguide               CLOB,
```

```
materialize             BOOLEAN  DEFAULT FALSE,
mvrefreshmode           NUMBER   DEFAULT MV_REFRESH_ON_STATEMENT,
path                    VARCHAR2 DEFAULT '$',
resolvenameconflicts    BOOLEAN  DEFAULT FALSE,
colnameprefix           VARCHAR2 DEFAULT NULL,
mixedcasecolumns        BOOLEAN DEFAULT TRUE);
```

Parameters

Table 100-9 DBMS_JSON.GET_VIEW_SQL Procedure Parameters

Parameter	Description
viewname	Name of the view.
tablename	Name of the table containing JSON column jcolname.
jcolname	Name of the JSON column in table tablename that is used to create the view.
dataguide	The data guide.
materialize	The value of this parameter is boolean and indicates if the view is materialized or not.
mvrefreshmode	When materialize is true, this parameter specifies the materialized view refresh mode. For more information on materialized view refresh mode options, see DBMS_JSON Constants.
path	The path of the JSON field to be expanded. It uses JSON path-expression syntax. It expands the descendants under the specified path, and creates view columns for each scalar value in the resulting sub-tree. The path $ creates a view starting from the JSON document root.
resolvenameconflicts	By default, if there are any conflicts among o:preferred_column_name, an error is raised. By setting this parameter to TRUE, the procedure automatically resolves the virtual column name conflicts by appending a sequence number. The default value is FALSE.
colnameprefix	By default, the view column name is the same as the JSON field name. This parameter allows users to provide a prefix to prepend to the view column names.
mixedcasecolumns	By default, the view column names are case sensitive. You can use this parameter to change the case sensitivity behavior of the view column names.

Usage Notes

- When viewname is NULL, the procedure returns only the select statement of the view DDL and it can select more than 1000 columns.
- When viewname is not NULL, the procedure returns create view DDL and it selects at most 1000 columns.
- As one json_table can only produce at most 1000 columns, the procedure will split paths into joins among multiple json_tables if the paths are more than 1000, when viewname is NULL.

100.4.7 RENAME_COLUMN Procedure

This procedure sets the preferred name for a JSON column, to be used by the create view, or add virtual columns procedure.

> **See Also:**
>
> *Oracle Database JSON Developer's Guide*

Syntax

```
PROCEDURE RENAME_COLUMN(
   tablename VARCHAR2,
   jcolname VARCHAR2,
   path VARCHAR2,
   type NUMBER,
   preferred_name VARCHAR2);
```

Parameters

Table 100-10 RENAME_COLUMN Procedure Parameters

Parameter	Description
`tablename`	Name of the table containing JSON column `jcolname`.
`jcolname`	Name of the JSON column in table `tablename`. It must have a data guide-enabled JSON search index, or else an error is raised.
`path`	Path to the JSON field on which to set the preferred column name.
`type`	The type of the JSON field targeted by `path`. Two JSON fields can have the same path if they are of different types. Possible values: • `TYPE_NULL` • `TYPE_STRING` • `TYPE_NUMBER` • `TYPE_BOOLEAN` • `TYPE_OBJECT` • `TYPE_ARRAY`
`preferred_name`	Preferred name for the JSON field specified by `path`. If there is a name conflict, a system generated name is used instead.

Example 100-2 Example Renaming a Column

This example renames a field to item_name.

```
EXEC DBMS_JSON.RENAME_COLUMN('T1', 'PO', '$.purchaseOrder.items.name',
DBMS_JSON.TYPE_STRING, 'item_name');
```

101
DBMS_LDAP

The DBMS_LDAP package lets you access data from LDAP servers.

For a complete description of this package within the context of Oracle Internet Directory, see `DBMS_LDAP` in the *Application Developer's Guide for Oracle Identity Management*.

102
DBMS_LDAP_UTL

The DBMS_LDAP_UTL package contains the Oracle Extension utility functions.

For a complete description of this package within the context of Oracle Internet Directory, see `DBMS_LDAP_UTL` in the *Application Developer's Guide for Oracle Identity Management*.

103
DBMS_LIBCACHE

The DBMS_LIBCACHE package consists of one subprogram that prepares the library cache on an Oracle instance by extracting SQL and PL/SQL from a remote instance and compiling this SQL locally without execution. The value of compiling the cache of an instance is to prepare the information the application requires to execute in advance of failover or switchover.

This chapter contains the following topics:

- Overview
- Security Model
- Summary of DBMS_LIBCACHE Subprograms

103.1 DBMS_LIBCACHE Overview

Compiling a shared cursor consists of open, parse, and bind operations, plus the type-checking and execution plan functions performed at the first execution. All of these steps are executed in advance by the package DBMS_LIBCACHE for SELECT statements.

The open and parse functions are executed in advance for PL/SQL and DML. For PL/SQL, executing the parse phase has the effect of loading all library cache heaps other than the MCODE.

103.2 DBMS_LIBCACHE Security Model

To execute DBMS_LIBCACHE you must directly access the same objects as do SQL statements. You can best accomplish this by utilizing the same user id as the original system on the remote system.

When there are multiple schema users, DBMS_LIBCACHE should be called for each.

Alternatively, DBMS_LIBCACHE may be called with the generic user PARSER. However, this user cannot parse the SQL that uses objects with access granted though roles. This is a standard PL/SQL security limitation.

103.3 Summary of DBMS_LIBCACHE Subprograms

The DBMS_LIBCACHE package includes the COMPILE_FROM_REMOTE procedure subprogram.

Table 103-1 ***DBMS_LIBCACHE Package Subprograms***

Subprogram	Description
COMPILE_FROM_REMOTE Procedure	Extracts SQL in batch from the source instance and compiles the SQL at the target instance

103.3.1 COMPILE_FROM_REMOTE Procedure

This procedure extracts SQL in batch from the source instance and compiles the SQL at the target instance.

Syntax

```
DBMS_LIBCACHE.COMPILE_FROM_REMOTE (
   p_db_link                IN     dbms_libcache$def.db_link%type,
   p_username               IN     VARCHAR2 default null,
   p_threshold_executions   IN     NATURAL  default 3,
   p_threshold_sharable_mem IN     NATURAL  default 1000,
   p_parallel_degree        IN     NATURAL  default 1);
```

Parameters

Table 103-2 COMPILE_FROM_REMOTE Procedure Parameters

Parameter	Description
p_db_link	Database link to the source name (mandatory). The database link pointing to the instance that will be used for extracting the SQL statements. The user must have the role SELECT_ON_CATALOG at the source instance. For improved security, the connection may use a password file or LDAP authentication. The database link is mandatory only for releases with dbms_libcache$def.ACCESS_METHOD = DB_LINK_METHOD
p_instance_name	(Reserved for future use). The name of the instance that will be used for extracting the SQL statements. The instance name must be unique for all instances excluding the local instance. The name is not case sensitive.
p_username	Source username (default is all users). The name of the username that will be used for extracting the SQL statements. The username is an optional parameter that is used to ensure the parsing user id is the same as that on the source instance. For an application where users connect as a single user_id, for example APPS, APPS is the parsing user_id that is recorded in the shared pool. To select only SQL statements parsed by APPS, enter the string 'APPS' in this field. To also select statements executed by batch, repeat the executing the procedure with the schema owner, for example GL. If the username is supplied, it must be valid. The name is not case sensitive.
p_threshold_executions	The lower bound for the number of executions, below which a SQL statement will not be selected for parsing. This parameter is optional. It allows the application to extract and compile statements with executions, for example, greater than 3. The default value is 1. This means SQL statements that have never executed, including invalid SQL statements, will not be extracted.

Table 103-2 (Cont.) COMPILE_FROM_REMOTE Procedure Parameters

Parameter	Description
p_threshold_sharable_mem	The lower bound for the size of the shared memory consumed by the cursors on the source instance. Below this value a SQL statement will not be selected for parsing. This parameter is optional. It allows the application to extract and compile statements with shared memory for example, greater than 10000 bytes.
p_parallel_degree	The number of parallel jobs that execute to complete the parse operation. These tasks are spawned as parallel jobs against a sub-range of the SQL statements selected for parsing. This parameter is reserved for parallel compile jobs which are currently not implemented.

104
DBMS_LOB

The DBMS_LOB package provides subprograms to operate on BLOBs, CLOBs, NCLOBs, BFILEs, and temporary LOBs. You can use DBMS_LOB to access and manipulate specific parts of a LOB or complete LOBs.

This chapter contains the following topics:

- Overview
- Security Model
- Constants
- Datatypes
- Operational Notes
- Rules and Limits
- Exceptions
- Summary of DBMS_LOB Subprograms

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide*

104.1 DBMS_LOB Overview

DBMS_LOB can read and modify BLOBs, CLOBs, and NCLOBs; it provides read-only operations for BFILEs. The bulk of the LOB operations are provided by this package.

104.2 DBMS_LOB Security Model

This package must be created under SYS. Operations provided by this package are performed under the current calling user, not under the package owner SYS.

Any DBMS_LOB subprogram called from an anonymous PL/SQL block is executed using the privileges of the current user. Any DBMS_LOB subprogram called from a stored procedure is executed using the privileges of the owner of the stored procedure.

When creating the procedure, users can set the AUTHID to indicate whether they want definer's rights or invoker's rights. For example:

```
CREATE PROCEDURE proc1 AUTHID DEFINER ...
```

or

```
CREATE PROCEDURE proc1 AUTHID CURRENT_USER ...
```

> **See Also:**
>
> For more information on AUTHID and privileges, see *Oracle Database PL/SQL Language Reference*

You can provide secure access to BFILEs using the DIRECTORY feature discussed in BFILENAME function in the*Oracle Database SecureFiles and Large Objects Developer's Guide* and the *Oracle Database SQL Language Reference*.

For information about the security model pertaining to temporary LOBs, see Operational Notes.

104.3 DBMS_LOB Constants

This topic describes the constants used by the DBMS_LOB package

These are shown in following tables:

- Table 104-1
- Table 104-2
- Table 104-3
- Table 104-4
- Table 104-5
- Table 104-6

Table 104-1 DBMS_LOB Constants - Basic

Constant	Type	Value	Description
CALL	PLS_INTEGER	12	Create the TEMP LOB with call duration
FILE_READONLY	BINARY_INTEGER	0	Open the specified BFILE read-only
LOB_READONLY	BINARY_INTEGER	0	Open the specified LOB read-only
LOB_READWRITE	BINARY_INTEGER	1	Open the specified LOB read-write
LOBMAXSIZE	INTEGER	18446744073709551615	Maximum size of a LOB in bytes
SESSION	PLS_INTEGER	10	Create the TEMP LOB with session duration

Table 104-2 DBMS_LOB Constants - Option Types

Constant	Definition	Value	Description
OPT_COMPRESS	BINARY_INTEGER	1	Set/Get the SECUREFILE compress option value

Table 104-2 (Cont.) DBMS_LOB Constants - Option Types

Constant	Definition	Value	Description
OPT_DEDUPLICATE	BINARY_INTEGER	4	Set/Get the SECUREFILE Deduplicate option value
OPT_ENCRYPT	BINARY_INTEGER	2	Get the SECUREFILE encrypt option value

Table 104-3 DBMS_LOB Constants - Option Values

Constant	Definition	Value	Description
COMPRESS_OFF	BINARY_INTEGER	0	For SETOPTIONS Procedures, set compress off; for GETOPTIONS Functions, compress is off
COMPRESS_ON	BINARY_INTEGER	1	For SETOPTIONS Procedures, set compress on; for GETOPTIONS Functions, compress is on
DEDUPLICATE_OFF	BINARY_INTEGER	0	For SETOPTIONS Procedures, set deduplicate is off; for GETOPTIONS Functions, deduplicate is off
DEDUPLICATE_ON	BINARY_INTEGER	4	For SETOPTIONS Procedures, set deduplicate is on; for GETOPTIONS Functions, deduplicate is on
ENCRYPT_OFF	BINARY_INTEGER	0	For GETOPTIONS Functions, encrypt is off
ENCRYPT_ON	BINARY_INTEGER	2	For GETOPTIONS Functions, encrypt is on

Table 104-4 DBMS_LOB Constants - DBFS State Value Types

Constant	Definition	Value	Description
DBFS_LINK_NEVER	PLS_INTEGER	0	LOB has never been archived
DBFS_LINK_NO	PLS_INTEGER	2	LOB was archived, but as been read back in to the RDBMS
DBFS_LINK_YES	PLS_INTEGER	1	LOB is currently archived

Table 104-5 DBMS_LOB Constants - DBFS Cache Flags

Constant	Definition	Value	Description
DBFS_LINK_CACHE	PLS_INTEGER	1	Put the LOB data to the archive, but keep the data in the RDBMS as a cached version
DBFS_LINK_NOCACHE	PLS_INTEGER	0	Put the LOB data to the archive, and remove the data from the RDBMS.

Table 104-6 DBMS_LOB Constants - Miscellaneous

Constant	Definition	Value	Description
CONTENTTYPE_MAX_SIZE	PLS_INTEGER	128	Maximum number of bytes allowed in the content type string
DBFS_LINK_PATH_MAX_SIZE	PLS_INTEGER	1024	The maximum length of DBFS pathnames

104.4 DBMS_LOB Datatypes

The table in this topic describes the datatypes used by DBMS_LOB.

.

Table 104-7 Datatypes Used by DBMS_LOB

Type	Description
BLOB	Source or destination binary LOB.
RAW	Source or destination RAW buffer (used with BLOB).
CLOB	Source or destination character LOB (including NCLOB).
VARCHAR2	Source or destination character buffer (used with CLOB and NCLOB).
INTEGER	Specifies the size of a buffer or LOB, the offset into a LOB, or the amount to access.
BFILE	Large, binary object stored outside the database.

The DBMS_LOB package defines no special types.

An NCLOB is a CLOB for holding fixed-width and varying-width, multibyte national character sets.

The clause ANY_CS in the specification of DBMS_LOB subprograms for CLOBs enables the CLOB type to accept a CLOB or NCLOB locator variable as input.

104.5 DBMS_LOB Operational Notes

All DBMS_LOB subprograms work based on LOB locators. For the successful completion of DBMS_LOB subprograms, you must provide an input locator that represents a LOB that already exists in the database tablespaces or external file system.

See also Chapter 1 of *Oracle Database SecureFiles and Large Objects Developer's Guide*

Starting from 12.2 release, you can select a persistent LOB locator from a remote table into a local variable. The remote column can be of type BLOB, CLOB, or NCLOB. You cannot select BFILE from a remote table. The LOB variable that refers to the LOB value in a remote table is called a remote locator.

All the DBMS_LOB APIs other than the ones that are meant for BFILEs will now accept and support operations on remote LOB locators. All the APIs that take in two locators must have both LOBs collocated at one database.

> **See Also:**
>
> *Distributed LOBs* chapter in *Oracle Database SecureFiles and Large Objects Developer's Guide*.

To use LOBs in your database, you must first use SQL data definition language (DDL) to define the tables that contain LOB columns.

- Internal LOBs
- External LOBs
- Temporary LOBs

Internal LOBs

To populate your table with internal LOBs after LOB columns are defined in a table, you use the SQL data manipulation language (DML) to initialize or populate the locators in the LOB columns.

External LOBs

For an external LOB (BFILE) to be represented by a LOB locator, you must:

- Ensure that a DIRECTORY object representing a valid, existing physical directory has been defined, and that physical files (the LOBs you plan to add) exist with read permission for the database. If your operating system uses case-sensitive path names, then be sure you specify the directory in the correct format.
- Pass the DIRECTORY object and the filename of the external LOB you are adding to the BFILENAME function to create a LOB locator for your external LOB.

Once you have completed these tasks, you can insert or update a row containing a LOB column using the specified LOB locator.

After the LOBs are defined and created, you can then SELECT from a LOB locator into a local PL/SQL LOB variable and use this variable as an input parameter to DBMS_LOB for access to the LOB value.

For details on the different ways to do this, See *Oracle Database SecureFiles and Large Objects Developer's Guide*

Temporary LOBs

The database supports the definition, creation, deletion, access, and update of temporary LOBs. Your temporary tablespace stores the temporary LOB data. Temporary LOBs are not permanently stored in the database. Their purpose is mainly to perform transformations on LOB data.

For temporary LOBs, you must use the OCI, PL/SQL, or another programmatic interface to create or manipulate them. Temporary LOBs can be either BLOBs, CLOBs, or NCLOBs.

A temporary LOB is empty when it is created. By default, all temporary LOBs are deleted at the end of the session in which they were created. If a process dies unexpectedly or if the database crashes, then temporary LOBs are deleted, and the space for temporary LOBs is freed.

There is also an interface to let you group temporary LOBs together into a logical bucket. The duration represents this logical store for temporary LOBs. Each temporary LOB can have separate storage characteristics, such as `CACHE`/ `NOCACHE`. There is a default store for every session into which temporary LOBs are placed if you don't specify a specific duration. Additionally, you are able to perform a free operation on durations, which causes all contents in a duration to be freed.

There is no support for consistent read (CR), undo, backup, parallel processing, or transaction management for temporary LOBs. Because CR and roll backs are not supported for temporary LOBs, you must free the temporary LOB and start over again if you encounter an error.

Because CR, undo, and versions are not generated for temporary LOBs, there is potentially a performance impact if you assign multiple locators to the same temporary LOB. Semantically, each locator should have its own copy of the temporary LOB.

A copy of a temporary LOB is created if the user modifies the temporary LOB while another locator is also pointing to it. The locator on which a modification was performed now points to a new copy of the temporary LOB. Other locators no longer see the same data as the locator through which the modification was made. A deep copy was not incurred by permanent LOBs in these types of situations, because CR snapshots and version pages enable users to see their own versions of the LOB cheaply.

You can gain pseudo-`REF` semantics by using pointers to locators in OCI and by having multiple pointers to locators point to the same temporary LOB locator, if necessary. In PL/SQL, you must avoid using more than one locator for each temporary LOB. The temporary LOB locator can be passed by reference to other procedures.

Because temporary LOBs are not associated with any table schema, there are no meanings to the terms in-row and out-of-row temporary LOBs. Creation of a temporary LOB instance by a user causes the engine to create and return a locator to the LOB data. The PL/SQL `DBMS_LOB` package, PRO*C/C++, OCI, and other programmatic interfaces operate on temporary LOBs through these locators just as they do for permanent LOBs.

There is no support for client side temporary LOBs. All temporary LOBs reside in the server.

Temporary LOBs do not support the `EMPTY_BLOB` or `EMPTY_CLOB` functions that are supported for permanent LOBs. The `EMPTY_BLOB` function specifies the fact that the LOB is initialized, but not populated with any data.

A temporary LOB instance can only be destroyed by using OCI or the `DBMS_LOB` package by using the appropriate `FREETEMPORARY` or `OCIDurationEnd` statement.

A temporary LOB instance can be accessed and modified using appropriate OCI and `DBMS_LOB` statements, just as for regular permanent internal LOBs. To make a temporary LOB permanent, you must explicitly use the OCI or `DBMS_LOB COPY` command, and copy the temporary LOB into a permanent one.

Security is provided through the LOB locator. Only the user who created the temporary LOB is able to see it. Locators are not expected to be able to pass from one user's

session to another. Even if someone did pass a locator from one session to another, they would not access the temporary LOBs from the original session. Temporary LOB lookup is localized to each user's own session. Someone using a locator from somewhere else is only able to access LOBs within his own session that have the same LOB ID. Users should not try to do this, but if they do, they are not able to affect anyone else's data.

The database keeps track of temporary LOBs for each session in a v$ view called V$TEMPORARY_LOBS, which contains information about how many temporary LOBs exist for each session. V$ views are for DBA use. From the session, the database can determine which user owns the temporary LOBs. By using V$TEMPORARY_LOBS in conjunction with DBA_SEGMENTS, a DBA can see how much space is being used by a session for temporary LOBs. These tables can be used by DBAs to monitor and guide any emergency cleanup of temporary space used by temporary LOBs.

The following notes are specific to temporary LOBs:

1. All functions in DBMS_LOB return NULL if any of the input parameters are NULL. All procedures in DBMS_LOB raise an exception if the LOB locator is input as NULL.
2. Operations based on CLOBs do not verify if the character set IDs of the parameters (CLOB parameters, VARCHAR2 buffers and patterns, and so on) match. It is the user's responsibility to ensure this.
3. Data storage resources are controlled by the DBA by creating different temporary tablespaces. DBAs can define separate temporary tablespaces for different users, if necessary.

>
> *Oracle Database PL/SQL Language Reference* for more information on NOCOPY syntax

104.6 DBMS_LOB Rules and Limits

This topic describes general DBMS_LOB rules and limits, rules and limits specific to external files (BFILEs), and maximum LOB and buffer sizes.

General Rules and Limits

- Oracle Database does not support constraints on columns or attributes whose type is a LOB, with the following exception: NOT NULL constraints are supported for a LOB column or attribute.
- The following rules apply in the specification of subprograms in this package:
  - newlen, offset, and amount parameters for subprograms operating on BLOBs and BFILEs must be specified in terms of *bytes*.
  - newlen, offset, and amount parameters for subprograms operating on CLOBs must be specified in terms of *characters*.

  In multi-byte character sets, it is not possible to interpret these offsets correctly. As a result, SUBSTR raises the following error: ORA-22998: CLOB or NCLOB in multibyte character set not supported.

- A subprogram raises an INVALID_ARGVAL exception if the following restrictions are not followed in specifying values for parameters (unless otherwise specified):

  1. Only positive, absolute offsets from the beginning of LOB data are permitted: Negative offsets from the tail of the LOB are not permitted.
  2. Only positive, nonzero values are permitted for the parameters that represent size and positional quantities, such as amount, offset, newlen, nth, and so on. Negative offsets and ranges observed in SQL string functions and operators are not permitted.
  3. The value of offset, amount, newlen, nth must not exceed the value lobmaxsize 18446744073709551615 (2^{64}) in any DBMS_LOB subprogram.
  4. For CLOBs consisting of fixed-width multibyte characters, the maximum value for these parameters must not exceed (lobmaxsize/ character_width_in_bytes) characters.

     For example, if the CLOB consists of 2-byte characters, such as:

     ```
     JA16SJISFIXED
     ```

     Then, the maximum amount value should not exceed:

     ```
     18446744073709551615/2 = 9223372036854775807
     ```

- PL/SQL language specifications stipulate an upper limit of 32767 bytes (not characters) for RAW and VARCHAR2 parameters used in DBMS_LOB subprograms. For example, if you declare a variable to be:

  ```
  charbuf VARCHAR2(3000)
  ```

  Then, charbuf can hold 3000 single byte characters or 1500 2-byte fixed width characters. This has an important consequence for DBMS_LOB subprograms for CLOBs and NCLOBs.

- The %CHARSET clause indicates that the form of the parameter with %CHARSET must match the form of the ANY_CS parameter to which it refers.

  For example, in DBMS_LOB subprograms that take a VARCHAR2 buffer parameter, the form of the VARCHAR2 buffer must match the form of the CLOB parameter. If the input LOB parameter is of type NCLOB, then the buffer must contain NCHAR data. Conversely, if the input LOB parameter is of type CLOB, then the buffer must contain CHAR data.

  For DBMS_LOB subprograms that take two CLOB parameters, both CLOB parameters must have the same form; that is, they must both be NCLOBs, or they must both be CLOBs.

- If the value of amount plus the offset exceeds the maximum LOB size allowed by the database, then access exceptions are raised.

  Under these input conditions, read subprograms, such as READ, COMPARE, INSTR, and SUBSTR, read until End of Lob/File is reached. For example, for a READ operation on a BLOB or BFILE, if the user specifies offset value of 3 GB and an amount value of 2 GB on a LOB that is 4GB in size, then READ returns only 1GB (4GB-3GB) bytes.

- Functions with NULL or invalid input values for parameters return a NULL. Procedures with NULL values for destination LOB parameters raise exceptions.

- Operations involving patterns as parameters, such as COMPARE, INSTR, and SUBSTR do not support regular expressions or special matching characters (such as % in the LIKE operator in SQL) in the pattern parameter or substrings.
- The End Of LOB condition is indicated by the READ procedure using a NO_DATA_FOUND exception. This exception is raised only upon an attempt by the user to read beyond the end of the LOB. The READ buffer for the last read contains 0 bytes.
- For consistent LOB updates, you must lock the row containing the destination LOB before making a call to any of the procedures (mutators) that modify LOB data.
- Unless otherwise stated, the default value for an offset parameter is 1, which indicates the first byte in the BLOB or BFILE data, and the first character in the CLOB or NCLOB value. No default values are specified for the amount parameter — you must input the values explicitly.
- You must lock the row containing the destination internal LOB before calling any subprograms that modify the LOB, such as APPEND, COPY, ERASE, TRIM, or WRITE. These subprograms do not implicitly lock the row containing the LOB.

Rules and Limits Specific to External Files (BFILEs)

- The subprograms COMPARE, INSTR, READ, SUBSTR, FILECLOSE, FILECLOSEALL and LOADFROMFILE operate only on an *opened* BFILE locator; that is, a successful FILEOPEN call must precede a call to any of these subprograms.
- For the functions FILEEXISTS, FILEGETNAME and GETLENGTH, a file's open/close status is unimportant; however, the file must exist physically, and you must have adequate privileges on the DIRECTORY object and the file.
- DBMS_LOB does not support any concurrency control mechanism for BFILE operations.
- In the event of several open files in the session whose closure has not been handled properly, you can use the FILECLOSEALL subprogram to close all files opened in the session and resume file operations from the beginning.
- If you are the creator of a DIRECTORY, or if you have system privileges, then use the CREATE OR REPLACE, DROP, and REVOKE statements in SQL with extreme caution.

  If you, or other grantees of a particular directory object, have several open files in a session, then any of the preceding commands can adversely affect file operations. In the event of such abnormal termination, your only choice is to invoke a program or anonymous block that calls FILECLOSEALL, reopen your files, and restart your file operations.
- All files opened during a user session are implicitly closed at the end of the session. However, Oracle strongly recommends that you close the files after *both* normal and abnormal termination of operations on the BFILE.

  In the event of normal program termination, proper file closure ensures that the number of files that are open simultaneously in the session remains less than SESSION_MAX_OPEN_FILES.

  In the event of abnormal program termination from a PL/SQL program, it is imperative that you provide an exception handler that ensures closure of all files opened in that PL/SQL program. This is necessary because after an exception occurs, only the exception handler has access to the BFILE variable in its most current state.

  After the exception transfers program control outside the PL/SQL program block, all references to the open BFILEs are lost. The result is a larger open file count which may or may not exceed the SESSION_MAX_OPEN_FILES value.

For example, consider a `READ` operation past the end of the `BFILE` value, which generates a `NO_DATA_FOUND` exception:

```
-- This assumes a directory 'DDD' whose path is already known
DECLARE
       fil BFILE:= bfilename('DDD', 'filename.foo');
       pos INTEGER;
       amt BINARY_INTEGER;
       buf RAW(40);
BEGIN
       SELECT ad_graphic INTO fil FROM print_media WHERE product_id = 3106;
       dbms_lob.open(fil, dbms_lob.lob_readonly);
       amt := 40; pos := 1 + dbms_lob.getlength(fil); buf := '';
       dbms_lob.read(fil, amt, pos, buf);
       dbms_output.put_line('Read F1 past EOF: '||
           utl_raw.cast_to_varchar2(buf));
       dbms_lob.close(fil);
END;

ORA-01403: no data found
ORA-06512: at "SYS.DBMS_LOB", line 373
ORA-06512: at line 10
```

After the exception has occurred, the `BFILE` locator variable file goes out of scope, and no further operations on the file can be done using that variable. Therefore, the solution is to use an exception handler:

```
DECLARE
     fil BFILE;
     pos INTEGER;
     amt BINARY_INTEGER;
     buf RAW(40);
BEGIN
     SELECT ad_graphic INTO fil FROM print_media WHERE product_id = 3106;
     dbms_lob.open(fil, dbms_lob.lob_readonly);
     amt := 40; pos := 1 + dbms_lob.getlength(fil); buf := '';
     dbms_lob.read(fil, amt, pos, buf);
     dbms_output.put_line('Read F1 past EOF: '||
          utl_raw.cast_to_varchar2(buf));
     dbms_lob.close(fil);
     exception
     WHEN no_data_found
     THEN
       BEGIN
         dbms_output.put_line('End of File reached. Closing file');
         dbms_lob.fileclose(fil);
         -- or dbms_lob.filecloseall if appropriate
       END;
END;
     /

Statement processed.
End of File reached. Closing file
```

In general, you should ensure that files opened in a PL/SQL block using `DBMS_LOB` are closed before normal or abnormal termination of the block.

Maximum LOB Size

The maximum size for LOBs supported by the database is equal to the value of the blocksize of the tablespace the LOB column resides in times the value 2^{32}-1 (4294967295). This allows for a maximum LOB size ranging from 8 terabytes to 128 terabytes.

Maximum Buffer Size

The maximum buffer size, 32767 bytes.

For `BLOBs`, where buffer size is expressed in bytes, the number of bytes cannot exceed 32767.

For `CLOBs` or `NCLOBs`, where buffer size is expressed in characters, the number of characters cannot result in a buffer larger than 32767 bytes. For example, if you are using fixed-width, two-byte characters, then specifying 20000 characters is an error (20000*2 = 40000, which is greater than 32767).

104.7 DBMS_LOB Exceptions

The table in the topic describes the exceptions for DBMS_LOB.

Table 104-8 DBMS_LOB Exceptions

Exception	Code	Description
`ACCESS_ERROR`	`22925`	You are trying to write too much data to the LOB: LOB size is limited to 4 gigabytes.
`CONTENTTYPE_TOOLONG`	`43859`	The length of the `contenttype` string exceeds the defined maximum. Modify the length of the `contenttype` string and retry the operation.
`CONTENTTYPEBUF_WRONG`	`43862`	The length of the `contenttype` buffer is less than defined constant. Modify the length of the `contenttype` buffer and retry the operation.
`INVALID_ARGVAL`	`21560`	The argument is expecting a non-`NULL`, valid value but the argument value passed in is `NULL`, invalid, or out of range.
`INVALID_DIRECTORY`	`22287`	The directory used for the current operation is not valid if being accessed for the first time, or if it has been modified by the DBA since the last access.
`NO_DATA_FOUND`	`1403`	`ENDOFLOB` indicator for looping read operations. This is not a hard error.
`NOEXIST_DIRECTORY`	`22285`	The directory leading to the file does not exist.
`NOPRIV_DIRECTORY`	`22286`	The user does not have the necessary access privileges on the directory or the file for the operation.
`OPEN_TOOMANY`	`22290`	The number of open files has reached the maximum limit.
`OPERATION_FAILED`	`22288`	The operation attempted on the file failed.
`QUERY_WRITE`	`14553`	Cannot perform a LOB write inside a query or PDML parallel execution server
`SECUREFILE_BADLOB`	`43856`	A non-`SECUREFILE` LOB type was used in a `SECUREFILE` only call

Table 104-8 (Cont.) DBMS_LOB Exceptions

Exception	Code	Description
SECUREFILE_BADPARAM	43857	An invalid argument was passed to a SECUREFILE subprogram
SECUREFILE_MARKERASED	43861	The mark provided to a FRAGMENT_* operation has been deleted
SECUREFILE_OUTOFBOUNDS	43883	Attempted to perform a FRAGMENT_* operation past the LOB end
UNOPENED_FILE	22289	The file is not open for the required operation to be performed.
VALUE_ERROR	6502	PL/SQL error for invalid values to subprogram's parameters.

104.8 Summary of DBMS_LOB Subprograms

This table lists the DBMS_LOB subprograms and briefly describes them.

Table 104-9 DBMS_LOB Package Subprograms

Subprogram	Description
APPEND Procedures	Appends the contents of the source LOB to the destination LOB
CLOB2FILE Procedure	Writes the content of a CLOB into a file.
CLOSE Procedure	Closes a previously opened internal or external LOB
COMPARE Functions	Compares two entire LOBs or parts of two LOBs
CONVERTTOBLOB Procedure	Reads character data from a source CLOB or NCLOB instance, converts the character data to the specified character, writes the converted data to a destination BLOB instance in binary format, and returns the new offsets
CONVERTTOCLOB Procedure	Takes a source BLOB instance, converts the binary data in the source instance to character data using the specified character, writes the character data to a destination CLOB or NCLOB instance, and returns the new offsets
COPY Procedures	Copies all, or part, of the source LOB to the destination LOB
COPY_DBFS_LINK Procedures	Copies the DBFS Link in the source LOB to the destination LOB
COPY_FROM_DBFS_LINK	Retrieves the data for the LOB from the DBFS store
CREATETEMPORARY Procedures	Creates a temporary BLOB or CLOB and its corresponding index in the user's default temporary tablespace
DBFS_LINK_GENERATE_PATH Functions	Returns a unique file path name for use in creating a DBFS Link
ERASE Procedures	Erases all or part of a LOB
FILECLOSE Procedure	Closes the file
FILECLOSEALL Procedure	Closes all previously opened files
FILEEXISTS Function	Checks if the file exists on the server
FILEGETNAME Procedure	Gets the directory object name and file name

Table 104-9 (Cont.) DBMS_LOB Package Subprograms

Subprogram	Description
FILEISOPEN Function	Checks if the file was opened using the input BFILE locators
FILEOPEN Procedure	Opens a file
FRAGMENT_DELETE Procedure	Deletes the data at the specified offset for the specified length from the LOB
FRAGMENT_INSERT Procedures	Inserts the specified data (limited to 32K) into the LOB at the specified offset
FRAGMENT_MOVE Procedure	Moves the amount of bytes (BLOB) or characters (CLOB/NCLOB) from the specified offset to the new offset specified
FRAGMENT_REPLACE Procedures	Replaces the data at the specified offset with the specified data (not to exceed 32k)
FREETEMPORARY Procedures	Frees the temporary BLOB or CLOB in the default temporary tablespace
GET_DBFS_LINK Functions	Returns the DBFS Link path associated with the specified SecureFile
GET_DBFS_LINK_STATE Procedures	Retrieves the current DBFS Link state of the specified SecureFile
GETCHUNKSIZE Functions	Returns the amount of space used in the LOB chunk to store the LOB value
GETCONTENTTYPE Functions	Returns the content ID string previously set by means of the SETCONTENTTYPE Procedure
GETLENGTH Functions	Gets the length of the LOB value
GETOPTIONS Functions	Obtains settings corresponding to the option_type field for a particular LOB
GET_STORAGE_LIMIT Function	Returns the storage limit for LOBs in your database configuration
INSTR Functions	Returns the matching position of the *nth* occurrence of the pattern in the LOB
ISOPEN Functions	Checks to see if the LOB was already opened using the input locator
ISREMOTE Function	Checks to see if the LOB is local to the database or if it belongs to a remote database.
ISSECUREFILE Function	Returns TRUE if the LOB locator passed to is for a SecureFiles LOB, otherwise, returns FALSE
ISTEMPORARY Functions	Checks if the locator is pointing to a temporary LOB
LOADBLOBFROMFILE Procedure	Loads BFILE data into an internal BLOB
LOADCLOBFROMFILE Procedure	Loads BFILE data into an internal CLOB
MOVE_TO_DBFS_LINK Procedures	Writes the specified SecureFile data to the DBFS store
OPEN Procedures	Opens a LOB (internal, external, or temporary) in the indicated mode
READ Procedures	Reads data from the LOB starting at the specified offset

Table 104-9 (Cont.) DBMS_LOB Package Subprograms

Subprogram	Description
SET_DBFS_LINK Procedures	Links the specified SecureFile to the specified path name. It does not copy the data to the path
SETCONTENTTYPE Procedure	Sets the content type string for the data in the LOB
SETOPTIONS Procedures	Enables CSCE features on a per-LOB basis, overriding the default LOB column settings
SUBSTR Functions	Returns part of the LOB value starting at the specified offset
TRIM Procedures	Trims the LOB value to the specified shorter length
WRITE Procedures	Writes data to the LOB from a specified offset
WRITEAPPEND Procedures	Writes a buffer to the end of a LOB

104.8.1 APPEND Procedures

This procedure appends the contents of a source internal LOB to a destination LOB. It appends the complete source LOB.

Syntax

```
DBMS_LOB.APPEND (
   dest_lob IN OUT  NOCOPY BLOB,
   src_lob  IN             BLOB);

DBMS_LOB.APPEND (
   dest_lob IN OUT  NOCOPY CLOB  CHARACTER SET ANY_CS,
   src_lob  IN             CLOB  CHARACTER SET dest_lob%CHARSET);
```

Parameters

Table 104-10 APPEND Procedure Parameters

Parameter	Description
dest_lob	Locator for the internal LOB to which the data is to be appended.
src_lob	Locator for the internal LOB from which the data is to be read.

Exceptions

Table 104-11 APPEND Procedure Exceptions

Exception	Description
VALUE_ERROR	Either the source or the destination LOB is NULL.
QUERY_WRITE	Cannot perform a LOB write inside a query or PDML parallel execution server

Usage Notes

- It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

  If you do not wrap the LOB operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the `OPEN` or `CLOSE` statement.
- If `APPEND` is called on a LOB that has been archived, it implicitly gets the LOB before the first byte is written
- If `APPEND` is called on a SecureFiles LOB that is a DBFS Link, an exception is thrown.

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.2 CLOB2FILE Procedure

This procedure writes the content of a `CLOB` into a `bfile`. This procedure gets called from the deprecated `dbms_xslprocessor.clob2file` internally.

Syntax

```
DBMS_LOB.CLOB2FILE(
   src_cl      IN  CLOB,
   file_loc    IN  VARCHAR2,
   file_name   IN  VARCHAR2,
   csid        IN  NUMBER   := 0,
   open_mode   IN  VARCHAR2 :='wb');
```

Parameters

Table 104-12 CLOB2FILE Procedure Parameters

Parameter	Description
`src_cl`	Source CLOB locator to write into a file
`file_loc`	Directory object name where the file is located
`file_name`	File name
`csid`	Character set id of the CLOB locator • Must be a valid Oracle id; otherwise returns an error • If the value is `0`, then the content of the output file will be in the database character set

Table 104-12 (Cont.) CLOB2FILE Procedure Parameters

Parameter	Description
open_mode	The mode to open the output file in. • wb — write byte mode, overwrites the file The default value is wb.

104.8.3 CLOSE Procedure

This procedure closes a previously opened internal or external LOB.

Syntax

```
DBMS_LOB.CLOSE (
   lob_loc    IN OUT NOCOPY BLOB);

DBMS_LOB.CLOSE (
   lob_loc    IN OUT NOCOPY CLOB CHARACTER SET ANY_CS);

DBMS_LOB.CLOSE (
   file_loc   IN OUT NOCOPY BFILE);
```

Parameters

Table 104-13 CLOSE Procedure Parameters

Parameter	Description
lob_loc	LOB locator. For more information, see Operational Notes.

Exceptions

No error is returned if the BFILE exists but is not opened. An error is returned if the LOB is not open.

Usage Notes

CLOSE requires a round-trip to the server for both internal and external LOBs. For internal LOBs, CLOSE triggers other code that relies on the close call, and for external LOBs (BFILEs), CLOSE actually closes the server-side operating system file.

It is not mandatory that you wrap all LOB operations inside the Open/Close interfaces. However, if you open a LOB, you must close it before you commit the transaction; an error is produced if you do not. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

It is an error to commit the transaction before closing all opened LOBs that were opened by the transaction. When the error is returned, the openness of the open LOBs is discarded, but the transaction is successfully committed. Hence, all the changes made to the LOB and non-LOB data in the transaction are committed, but the domain and function-based indexes are not updated. If this happens, you should rebuild the functional and domain indexes on the LOB column.

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.4 COMPARE Functions

This function compares two entire LOBs or parts of two LOBs.

Syntax

```
DBMS_LOB.COMPARE (
   lob_1            IN BLOB,
   lob_2            IN BLOB,
   amount           IN INTEGER := DBMS_LOB.LOBMAXSIZE,
   offset_1         IN INTEGER := 1,
   offset_2         IN INTEGER := 1)
  RETURN INTEGER;

DBMS_LOB.COMPARE (
   lob_1            IN CLOB  CHARACTER SET ANY_CS,
   lob_2            IN CLOB  CHARACTER SET lob_1%CHARSET,
   amount           IN INTEGER := DBMS_LOB.LOBMAXSIZE,
   offset_1         IN INTEGER := 1,
   offset_2         IN INTEGER := 1)
  RETURN INTEGER;

DBMS_LOB.COMPARE (
   lob_1            IN BFILE,
   lob_2            IN BFILE,
   amount           IN INTEGER,
   offset_1         IN INTEGER := 1,
   offset_2         IN INTEGER := 1)
  RETURN INTEGER;
```

Pragmas

```
pragma restrict_references(COMPARE, WNDS, WNPS, RNDS, RNPS);
```

Parameters

Table 104-14 COMPARE Function Parameters

Parameter	Description
lob_1	LOB locator of first target for comparison.
lob_2	LOB locator of second target for comparison.
amount	Number of bytes (for BLOBs) or characters (for CLOBs/NCLOBSs) to compare.
offset_1	Offset in bytes or characters on the first LOB (origin: 1) for the comparison.
offset_2	Offset in bytes or characters on the second LOB (origin: 1) for the comparison.

Return Values

- `INTEGER`: 0 if the comparison succeeds, nonzero if not.
- `NULL`, if any of `amount`, `offset_1` or `offset_2` is not a valid LOB offset value. A valid offset is within the range of 1 to `LOBMAXSIZE` inclusive.

Usage Notes

- You can only compare LOBs of the same datatype (`LOBs` of `BLOB` type with other `BLOBs`, and `CLOBs` with `CLOBs`, and `BFILEs` with `BFILEs`). For `BFILEs`, the file must be already opened using a successful `FILEOPEN` operation for this operation to succeed.
- `COMPARE` returns 0 if the data exactly matches over the range specified by the `offset` and `amount` parameters. `COMPARE` returns `-1` if the first `CLOB` is less than the second, and 1 if it is greater.
- For fixed-width *n*-byte `CLOBs`, if the input amount for `COMPARE` is specified to be greater than (`DBMS_LOB.LOBMAXSIZE`/*n*), then `COMPARE` matches characters in a range of size (`DBMS_LOB.LOBMAXSIZE`/*n*), or Max(length(clob1), length(clob2)), whichever is lesser.
- If `COMPARE` is called on any LOB that has been archived, it implicitly gets the LOB before the compare begins.
- If `COMPARE()` is called on a SecureFiles LOB that is a DBFS Link, the linked LOB is streamed from DBFS, if possible, otherwise an exception is thrown.

Exceptions

Table 104-15 COMPARE Function Exceptions for BFILE operations

Exception	Description
`UNOPENED_FILE`	File was not opened using the input locator.
`NOEXIST_DIRECTORY`	Directory does not exist.
`NOPRIV_DIRECTORY`	You do not have privileges for the directory.
`INVALID_DIRECTORY`	Directory has been invalidated after the file was opened.
`INVALID_OPERATION`	File does not exist, or you do not have access privileges on the file.

See Also:

Oracle Database SecureFiles and Large Objects Developer's Guide for additional details on usage of this procedure

104.8.5 CONVERTTOBLOB Procedure

This procedure reads character data from a source CLOB or NCLOB instance, converts the character data to the character set you specify, writes the converted data to a destination BLOB instance in binary format, and returns the new offsets.

You can use this interface with any combination of persistent or temporary LOB instances as the source or destination.

Syntax

```
DBMS_LOB.CONVERTTOBLOB(
  dest_lob       IN OUT     NOCOPY  BLOB,
  src_clob       IN         CLOB CHARACTER SET ANY_CS,
  amount         IN         INTEGER,
  dest_offset    IN OUT     INTEGER,
  src_offset     IN OUT     INTEGER,
  blob_csid      IN         NUMBER,
  lang_context   IN OUT     INTEGER,
  warning        OUT        INTEGER);
```

Parameters

Table 104-16 CONVERTTOBLOB Procedure Parameters

Parameter	Description
dest_lob	LOB locator of the destination LOB instance.
src_clob	LOB locator of the source LOB instance.
amount	Number of characters to convert from the source LOB. If you want to copy the entire LOB, pass the constant DBMS_LOB.LOBMAXSIZE. If you pass any other value, it must be less than or equal to the size of the LOB.
dest_offset	(IN) Offset in bytes in the destination LOB for the start of the write. Specify a value of 1 to start at the beginning of the LOB. (OUT) The new offset in bytes after the end of the write.
src_offset	(IN) Offset in characters in the source LOB for the start of the read. (OUT) Offset in characters in the source LOB right after the end of the read.
blob_csid	Desired character set ID of the converted data.
lang_context	(IN) Language context, such as shift status, for the current conversion. (OUT) The language context at the time when the current conversion is done. This information is returned so you can use it for subsequent conversions without losing or misinterpreting any source data. For the very first conversion, or if do not care, use the default value of zero.

Table 104-16 (Cont.) CONVERTTOBLOB Procedure Parameters

Parameter	Description
warning	(OUT) Warning message. This parameter indicates when something abnormal happened during the conversion. You are responsible for checking the warning message. Currently, the only possible warning is — inconvertible character. This occurs when the character in the source cannot be properly converted to a character in destination. The default replacement character (for example, '?') is used in place of the inconvertible character. The return value of this error message is defined as the constant warn_inconvertible_char in the DBMS_LOB package.

Usage Notes

Preconditions

Before calling the CONVERTTOBLOB procedure, the following preconditions must be met:

- Both the source and destination LOB instances must exist.
- If the destination LOB is a persistent LOB, the row must be locked. To lock the row, select the LOB using the FOR UPDATE clause of the SELECT statement.

Constants and Defaults

All parameters are required. You must pass a variable for each OUT or IN OUT parameter. You must pass either a variable or a value for each IN parameter.

Table 104-17 gives a summary of typical values for each parameter. The first column lists the parameter, the second column lists the typical value, and the last column describes the result of passing the value. Note that constants are used for some values. These constants are defined in the dbmslob.sql package specification file.

Table 104-17 DBMS_LOB.CONVERTTOBLOB Typical Values

Parameter	Value	Description
amount	LOBMAXSIZE (IN)	convert the entire file
dest_offset	1 (IN)	start from the beginning
src_offset	1 (IN)	start from the beginning
blob_csid	DEFAULT_CSID (IN)	default CSID, use same CSID as source LOB
lang_context	DEFAULT_LANG_CTX (IN)	default language context
warning	NO_WARNING (OUT)	no warning message, success
	WARN_INCONVERTIBLE_CHAR (OUT)	character in source cannot be properly converted

General Notes

- You must specify the desired character set for the destination LOB in the blob_csid parameter. You can pass a zero value for blob_csid. When you do so, the database assumes that the desired character set is the same as the source LOB character set.

- You must specify the offsets for both the source and destination LOBs, and the number of characters to copy from the source LOB. The `amount` and `src_offset` values are in characters and the `dest_offset` is in bytes. To convert the entire LOB, you can specify `LOBMAXSIZE` for the `amount` parameter.
- `CONVERTTOBLOB` gets the source and/or destination LOBs as necessary prior to conversion and write of the data.

Exceptions

Table 104-18 gives possible exceptions this procedure can throw. The first column lists the exception string and the second column describes the error conditions that can cause the exception.

Table 104-18 CONVERTTOBLOB Procedure Exceptions

Exception	Description
`VALUE_ERROR`	Any of the input parameters are `NULL` or `INVALID`.
`INVALID_ARGVAL`	One or more of the following: - `src_offset` or `dest_offset` < 1. - `src_offset` or `dest_offset` > `LOBMAXSIZE`. - `amount` < 1. - `amount` > `LOBMAXSIZE`.

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for more information on using LOBs in application development

104.8.6 CONVERTTOCLOB Procedure

This procedure takes a source `BLOB` instance, converts the binary data in the source instance to character data using the character set you specify, writes the character data to a destination `CLOB` or `NCLOB` instance, and returns the new offsets.

You can use this interface with any combination of persistent or temporary LOB instances as the source or destination.

Syntax

```
DBMS_LOB.CONVERTTOCLOB(
   dest_lob       IN OUT NOCOPY  CLOB CHARACTER SET ANY_CS,
   src_blob       IN             BLOB,
   amount         IN             INTEGER,
   dest_offset    IN OUT         INTEGER,
   src_offset     IN OUT         INTEGER,
   blob_csid      IN             NUMBER,
   lang_context   IN OUT         INTEGER,
   warning        OUT            INTEGER);
```

Parameters

Table 104-19 CONVERTTOCLOB Procedure Parameters

Parameter	Description
dest_lob	LOB locator of the destination LOB instance.
src_blob	LOB locator of the source LOB instance.
amount	Number of bytes to convert from the source LOB. If you want to copy the entire BLOB, pass the constant DBMS_LOB.LOBMAXSIZE. If you pass any other value, it must be less than or equal to the size of the BLOB.
dest_offset	(IN) Offset in characters in the destination LOB for the start of the write. Specify a value of 1 to start at the beginning of the LOB. (OUT) The new offset in characters after the end of the write. This offset always points to the beginning of the first complete character after the end of the write.
src_offset	(IN) Offset in bytes in the source LOB for the start of the read. (OUT) Offset in bytes in the source LOB right after the end of the read.
blob_csid	The character set ID of the source data
lang_context	(IN) Language context, such as shift status, for the current conversion. (OUT) The language context at the time when the current conversion is done. This information is returned so you can use it for subsequent conversions without losing or misinterpreting any source data. For the very first conversion, or if do not care, use the default value of zero.
warning	Warning message. This parameter indicates when something abnormal happened during the conversion. You are responsible for checking the warning message. Currently, the only possible warning is — inconvertible character. This occurs when the character in the source cannot be properly converted to a character in destination. The default replacement character (for example, '?') is used in place of the inconvertible character. The return value of this error message is defined as the constant warn_inconvertible_char in the DBMS_LOB package.

Usage Notes

Preconditions

Before calling the CONVERTTOCLOB procedure, the following preconditions must be met:

- Both the source and destination LOB instances must exist.
- If the destination LOB is a persistent LOB, the row must be locked before calling the CONVERTTOCLOB procedure. To lock the row, select the LOB using the FOR UPDATE clause of the SELECT statement.

Constants and Defaults

All parameters are required. You must pass a variable for each OUT or IN OUT parameter. You must pass either a variable or a value for each IN parameter.

Table 104-20 gives a summary of typical values for each parameter. The first column lists the parameter, the second column lists the typical value, and the last column describes the result of passing the value. Note that constants are used for some values. These constants are defined in the dbmslob.sql package specification file.

Table 104-20 DBMS_LOB.CONVERTTOCLOB Typical Values

Parameter	Value	Description
amount	LOBMAXSIZE (IN)	convert the entire file
dest_offset	1 (IN)	start from the beginning
src_offset	1 (IN)	start from the beginning
csid	DEFAULT_CSID (IN)	default CSID, use destination CSID
lang_context	DEFAULT_LANG_CTX (IN)	default language context
warning	NO_WARNING (OUT)	no warning message, success
	WARN_INCONVERTIBLE_CHAR (OUT)	character in source cannot be properly converted

General Notes

- You must specify the desired character set for the source LOB in the blob_csid parameter. You can pass a zero value for blob_csid. When you do so, the database assumes that the desired character set is the same as the destianation LOB character set.
- You must specify the offsets for both the source and destination LOBs, and the number of characters to copy from the source LOB. The amount and src_offset values are in bytes and the dest_offset is in characters. To convert the entire LOB, you can specify LOBMAXSIZE for the amount parameter.
- CONVERTTOCLOB gets the source and/or destination LOBs as necessary prior to conversion and write of the data.

Exceptions

Table 104-21 CONVERTTOCLOB Procedure Exceptions

Exception	Description
VALUE_ERROR	Any of the input parameters are NULL or INVALID.
INVALID_ARGVAL	One or more of the following: - src_offset or dest_offset < 1. - src_offset or dest_offset > LOBMAXSIZE. - amount < 1. - amount > LOBMAXSIZE.

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for more information on using LOBs in application development

104.8.7 COPY Procedures

This procedure copies all, or a part of, a source internal LOB to a destination internal LOB. You can specify the offsets for both the source and destination LOBs, and the number of bytes or characters to copy.

Syntax

```
DBMS_LOB.COPY (
  dest_lob    IN OUT NOCOPY BLOB,
  src_lob     IN            BLOB,
  amount      IN            INTEGER,
  dest_offset IN            INTEGER := 1,
  src_offset  IN            INTEGER := 1);

DBMS_LOB.COPY (
  dest_lob    IN OUT NOCOPY CLOB  CHARACTER SET ANY_CS,
  src_lob     IN            CLOB  CHARACTER SET dest_lob%CHARSET,
  amount      IN            INTEGER,
  dest_offset IN            INTEGER := 1,
  src_offset  IN            INTEGER := 1);
```

Parameters

Table 104-22 COPY Procedure Parameters

Parameter	Description
`dest_lob`	LOB locator of the copy target.
`src_lob`	LOB locator of source for the copy.
`amount`	Number of bytes (for `BLOB`s) or characters (for `CLOB`s) to copy.
`dest_offset`	Offset in bytes or characters in the destination LOB (origin: 1) for the start of the copy.
`src_offset`	Offset in bytes or characters in the source LOB (origin: 1) for the start of the copy.

Exceptions

Table 104-23 COPY Procedure Exceptions

Exception	Description
`VALUE_ERROR`	Any of the input parameters are `NULL` or invalid.

Table 104-23 (Cont.) COPY Procedure Exceptions

Exception	Description
INVALID_ARGVAL	Either: - src_offset or dest_offset < 1 - src_offset or dest_offset > LOBMAXSIZE - amount < 1 - amount > LOBMAXSIZE
QUERY_WRITE	Cannot perform a LOB write inside a query or PDML parallel execution server

Usage Notes

- If the offset you specify in the destination LOB is beyond the end of the data currently in this LOB, then zero-byte fillers or spaces are inserted in the destination BLOB or CLOB respectively. If the offset is less than the current length of the destination LOB, then existing data is overwritten.
- It is not an error to specify an amount that exceeds the length of the data in the source LOB. Thus, you can specify a large amount to copy from the source LOB, which copies data from the src_offset to the end of the source LOB.
- It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.
- If you do not wrap the LOB operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the OPEN or CLOSE statement.
- Prior to copy, the source and destination LOBs are retrieved, if they are currently archived. For a complete over-write, the destination LOB is not retrieved.
- If the source LOB is a DBFS Link, the data is streamed from DBFS, if possible, otherwise an exception is thrown. If the destination LOB is a DBFS Link, an exception is thrown.

See Also:

Oracle Database SecureFiles and Large Objects Developer's Guide for additional details on usage of this procedure

104.8.8 COPY_DBFS_LINK Procedures

This procedure copies the DBFS Link in the source LOB to the destination LOB.

Syntax

```
DBMS_LOB.COPY_DBFS_LINK (
  lob_loc_dst    IN OUT BLOB,
  lob_loc_src    IN     BLOB,
  flags          IN     PLS_INTEGER DEFAULT DBFS_LINK_NOCACHE);

DBMS_LOB.COPY_DBFS_LINK (
  lob_loc_dst    IN OUT CLOB CHARACTER SET ANY_CS,
  lob_loc_src    IN     CLOB CHARACTER SET ANY_CS,
  flags          IN     PLS_INTEGER DEFAULT DBFS_LINK_NOCACHE);
```

Parameters

Table 104-24 COPY_DBFS_LINK Procedure Parameters

Parameter	Description
lob_loc_dst	LOB to be made to reference the same storage data as lob_loc_src
lob_loc_src	LOB from which to copy the reference
flags	Options to COPY_DBFS_LINK: • DBFS_LINK_NOCACHE specifies to only copy the DBFS Link • DBFS_LINK_CACHE specifies to copy the DBFS Link and read the data into the database LOB specified by lob_loc_dst so that the data is cached

Exceptions

Table 104-25 COPY_DBFS_LINK Procedure Exceptions

Exception	Description
SECUREFILE_BADLOB	Either lob_loc_src or lob_loc_dst is not a SECUREFILE
INVALID_ARGVAL	lob_loc_src LOB has not been archived
ORA-01555	If the source LOB has been retrieved, never archived, or if the LOB has been migrated in and out (modified or not) since the locator was gotten.

104.8.9 COPY_FROM_DBFS_LINK

This procedure retrieves the archived SecureFiles LOB data from the DBFS HSM store and to the database.

Syntax

```
DBMS_LOB.COPY_FROM_DBFS_LINK (
  lob_loc        IN OUT BLOB);
```

```
DBMS_LOB.COPY_FROM_DBFS_LINK (
  lob_loc       IN OUT CLOB CHARACTER SET ANY_CS);
```

Parameters

Table 104-26 COPY_FROM_DBFS_LINK Procedure Parameters

Parameter	Description
lob_loc	LOB to be retrieved from the archive

Usage Note

COPY_FROM_DBFS_LINK does not remove the underlying DBFS file.

If the LOB is successfully retrieved, COPY_FROM_DBFS_LINK silently returns success.

Exceptions

Table 104-27 COPY_FROM_DBFS_LINK Procedure Exceptions

Exception	Description
SECUREFILE_BADLOB	lob_loc is not a SECUREFILE
ORA-01555	If the LOB has already been retrieved and has been modified since retrieval, if the LOB has been migrated in and out (modified or not) since the locator was retrieved

104.8.10 CREATETEMPORARY Procedures

This procedure creates a temporary BLOB or CLOB and its corresponding index in your default temporary tablespace.

Syntax

```
DBMS_LOB.CREATETEMPORARY (
   lob_loc IN OUT NOCOPY BLOB,
   cache   IN            BOOLEAN,
   dur     IN            PLS_INTEGER := DBMS_LOB.SESSION);

DBMS_LOB.CREATETEMPORARY (
   lob_loc IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,
   cache   IN            BOOLEAN,
   dur     IN            PLS_INTEGER := 10);
```

Parameters

Table 104-28 CREATETEMPORARY Procedure Parameters

Parameter	Description
lob_loc	LOB locator. For more information, see Operational Notes.
cache	Specifies if LOB should be read into buffer cache or not.

Table 104-28 (Cont.) CREATETEMPORARY Procedure Parameters

Parameter	Description
dur	1 of 2 predefined duration values (SESSION or CALL) which specifies a hint as to whether the temporary LOB is cleaned up at the end of the session or call. If dur is omitted, then the session duration is used.

See Also:

- *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure
- *Oracle Database PL/SQL Language Reference* for more information about NOCOPY and passing temporary lobs as parameters

104.8.11 DBFS_LINK_GENERATE_PATH Functions

This subprogram returns a unique file path name for use in creating a DBFS Link.

Syntax

```
DBMS_LOB.DBFS_LINK_GENERATE_PATH (
  lob_loc       IN BLOB,
  storage_dir   IN VARCHAR2)
 RETURN VARCHAR2;

DBMS_LOB.DBFS_LINK_GENERATE_PATH (
  lob_loc       IN CLOB CHARACTER SET ANY_CS,
  storage_dir   IN VARCHAR2)
 RETURN VARCHAR2;
```

Pragmas

```
PRAGMA RESTRICT_REFERENCES(dbfs_link_generate_path,
       WNDS, RNDS, WNPS, RNPS);
```

Parameters

Table 104-29 DBFS_LINK_GENERATE_PATH Function Parameters

Parameter	Description
lob_loc	LOB to be retrieved from DBFS
storage_dir	DBFS directory that will be the parent directory of the file

Exceptions

Table 104-30 DBFS_LINK_GENERATE_PATH Function Exceptions

Exception	Description
SECUREFILE_WRONGTYPE	lob_loc is not a SECUREFILE

Usage Notes

Returns a globally unique file pathname that can be used for archiving. This is guaranteed to be globally unique across all calls to this function for different LOBs and versions of that LOB. It is always the same for the same LOB and version.

104.8.12 ERASE Procedures

This procedure erases an entire internal LOB or part of an internal LOB.

Syntax

```
DBMS_LOB.ERASE (
   lob_loc           IN OUT   NOCOPY   BLOB,
   amount            IN OUT   NOCOPY   INTEGER,
   offset            IN                INTEGER := 1);

DBMS_LOB.ERASE (
   lob_loc           IN OUT   NOCOPY   CLOB CHARACTER SET ANY_CS,
   amount            IN OUT   NOCOPY   INTEGER,
   offset            IN                INTEGER := 1);
```

Parameters

Table 104-31 ERASE Procedure Parameters

Parameter	Description
lob_loc	Locator for the LOB to be erased.For more information, see Operational Notes.
amount	Number of bytes (for BLOBs or BFILES) or characters (for CLOBs or NCLOBs) to be erased.
offset	Absolute offset (origin: 1) from the beginning of the LOB in bytes (for BLOBs) or characters (CLOBs).

Usage Notes

- When data is erased from the middle of a LOB, zero-byte fillers or spaces are written for BLOBs or CLOBs respectively.
- The actual number of bytes or characters erased can differ from the number you specified in the amount parameter if the end of the LOB value is reached before erasing the specified number. The actual number of characters or bytes erased is returned in the amount parameter.
- ERASE gets the LOB if it is archived, unless the erase covers the entire LOB.
- If the LOB to be erased is a DBFS Link, an exception is thrown.

> **Note:**
>
> The length of the LOB is not decreased when a section of the LOB is erased. To decrease the length of the LOB value, see the "TRIM Procedures".

Exceptions

Table 104-32 ERASE Procedure Exceptions

Exception	Description
`VALUE_ERROR`	Any input parameter is `NULL`.
`INVALID_ARGVAL`	Either: - `amount` < 1 or `amount` > `LOBMAXSIZE` - `offset` < 1 or `offset` > `LOBMAXSIZE`
`QUERY_WRITE`	Cannot perform a LOB write inside a query or PDML parallel execution server

Usage Notes

It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

If you do not wrap the LOB operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the `OPEN` or `CLOSE` statement.

> **See Also:**
>
> - "TRIM Procedures"
> - *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.13 FILECLOSE Procedure

This procedure closes a `BFILE` that has already been opened through the input locator.

> **Note:**
>
> The database has only read-only access to `BFILEs`. This means that `BFILEs` cannot be written through the database.

Syntax

```
DBMS_LOB.FILECLOSE (
    file_loc IN OUT NOCOPY BFILE);
```

Parameters

Table 104-33 FILECLOSE Procedure Parameters

Parameter	Description
`file_loc`	Locator for the `BFILE` to be closed.

Exceptions

Table 104-34 FILECLOSE Procedure Exceptions

Exception	Description
`VALUE_ERROR`	`NULL` input value for `file_loc`.
`UNOPENED_FILE`	File was not opened with the input locator.
`NOEXIST_DIRECTORY`	Directory does not exist.
`NOPRIV_DIRECTORY`	You do not have privileges for the directory.
`INVALID_DIRECTORY`	Directory has been invalidated after the file was opened.
`INVALID_OPERATION`	File does not exist, or you do not have access privileges on the file.

> **See Also:**
>
> - "FILEOPEN Procedure"
> - "FILECLOSEALL Procedure"
> - *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.14 FILECLOSEALL Procedure

This procedure closes all BFILEs opened in the session.

Syntax

```
DBMS_LOB.FILECLOSEALL;
```

Exceptions

Table 104-35 FILECLOSEALL Procedure Exception

Exception	Description
UNOPENED_FILE	No file has been opened in the session.

> **See Also:**
>
> - "FILEOPEN Procedure"
> - "FILECLOSE Procedure"
> - *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.15 FILEEXISTS Function

This function finds out if a specified BFILE locator points to a file that actually exists on the server's file system.

Syntax

```
DBMS_LOB.FILEEXISTS (
   file_loc     IN    BFILE)
  RETURN INTEGER;
```

Pragmas

```
pragma restrict_references(FILEEXISTS, WNDS, RNDS, WNPS, RNPS);
```

Parameters

Table 104-36 FILEEXISTS Function Parameter

Parameter	Description
file_loc	Locator for the BFILE.

Return Values

Table 104-37 FILEEXISTS Function Return Values

Return	Description
0	Physical file does not exist.
1	Physical file exists.

Exceptions

Table 104-38 FILEEXISTS Function Exceptions

Exception	Description
NOEXIST_DIRECTORY	Directory does not exist.
NOPRIV_DIRECTORY	You do not have privileges for the directory.
INVALID_DIRECTORY	Directory has been invalidated after the file was opened.

See Also:

- "FILEISOPEN Function".
- *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.16 FILEGETNAME Procedure

This procedure determines the directory object and filename, given a BFILE locator.

This function only indicates the directory object name and filename assigned to the locator, not if the physical file or directory actually exists.

The maximum constraint values for the dir_alias buffer is 30, and for the entire path name, it is 2000.

Syntax

```
DBMS_LOB.FILEGETNAME (
   file_loc   IN    BFILE,
   dir_alias  OUT   VARCHAR2,
   filename   OUT   VARCHAR2);
```

Parameters

Table 104-39 FILEGETNAME Procedure Parameters

Parameter	Description
file_loc	Locator for the BFILE

Table 104-39 (Cont.) FILEGETNAME Procedure Parameters

Parameter	Description
dir_alias	Directory object name
filename	Name of the BFILE

Exceptions

Table 104-40 FILEGETNAME Procedure Exceptions

Exception	Description
VALUE_ERROR	Any of the input parameters are NULL or INVALID.
INVALID_ARGVAL	dir_alias or filename are NULL.

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.17 FILEISOPEN Function

This function finds out whether a BFILE was opened with the specified FILE locator.

Syntax

```
DBMS_LOB.FILEISOPEN (
   file_loc   IN    BFILE)
  RETURN INTEGER;
```

Pragmas

```
PRAGMA RESTRICT_REFERENCES(fileisopen, WNDS, RNDS, WNPS, RNPS);
```

Parameters

Table 104-41 FILEISOPEN Function Parameter

Parameter	Description
file_loc	Locator for the BFILE.

Return Values

INTEGER: 0 = file is not open, 1 = file is open

Usage Notes

If the input FILE locator was never passed to the FILEOPEN procedure, then the file is considered not to be opened by this locator. However, a different locator may have this file open. In other words, openness is associated with a specific locator.

Exceptions

Table 104-42 FILEISOPEN Function Exceptions

Exception	Description
NOEXIST_DIRECTORY	Directory does not exist.
NOPRIV_DIRECTORY	You do not have privileges for the directory.
INVALID_DIRECTORY	Directory has been invalidated after the file was opened.

See Also:

- "FILEEXISTS Function"
- *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.18 FILEOPEN Procedure

This procedure opens a BFILE for read-only access. BFILE data may not be written through the database.

Syntax

```
DBMS_LOB.FILEOPEN (
   file_loc   IN OUT NOCOPY  BFILE,
   open_mode  IN             BINARY_INTEGER := file_readonly);
```

Parameters

Table 104-43 FILEOPEN Procedure Parameters

Parameter	Description
file_loc	Locator for the BFILE.
open_mode	File access is read-only.

Exceptions

Table 104-44 FILEOPEN Procedure Exceptions

Exception	Description
VALUE_ERROR	file_loc or open_mode is NULL.

Table 104-44 (Cont.) FILEOPEN Procedure Exceptions

Exception	Description
INVALID_ARGVAL	open_mode is not equal to FILE_READONLY.
OPEN_TOOMANY	Number of open files in the session exceeds session_max_open_files.
NOEXIST_DIRECTORY	Directory associated with file_loc does not exist.
INVALID_DIRECTORY	Directory has been invalidated after the file was opened.
INVALID_OPERATION	File does not exist, or you do not have access privileges on the file.

See Also:

- "FILECLOSE Procedure"
- "FILECLOSEALL Procedure"
- *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.19 FRAGMENT_DELETE Procedure

This procedure deletes the data at the specified offset for the specified length from the LOB without having to rewrite all the data in the LOB following the specified offset.

Syntax

```
DBMS_LOB.FRAGMENT_DELETE (
   lob_loc     IN OUT NOCOPY BLOB,
   amount      IN            INTEGER,
   offset      IN            INTEGER);

DBMS_LOB.FRAGMENT_DELETE (
   lob_loc     IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,
   amount      IN            INTEGER,
   offset      IN            INTEGER);
```

Parameters

Table 104-45 FRAGMENT_DELETE Procedure Parameters

Parameter	Description
lob_loc	LOB locator. For more information, see Operational Notes.
amount	Number of bytes (BLOB) or characters (CLOB/NCLOB) to be removed from the LOB
offset	Offset into the LOB in bytes (BLOB) or characters (CLOB/NCLOB) to begin the deletion

Exceptions

Table 104-46 FRAGMENT_DELETE Procedure Exceptions

Exception	Description
INVALID_ARGVAL	A parameter value was invalid
QUERY_WRITE	Cannot perform operation during a query
SECUREFILE_BADLOB	A non-SECUREFILE LOB was used in a SECUREFILE LOB only call
SECUREFILE_OUTOFBOUNDS	Attempted to perform a FRAGMENT_* operation past LOB end

104.8.20 FRAGMENT_INSERT Procedures

This procedure inserts the specified data (limited to 32K) into the LOB at the specified offset.

Syntax

```
DBMS_LOB.FRAGMENT_INSERT (
   lob_loc     IN OUT NOCOPY BLOB,
   amount      IN            INTEGER,
   offset      IN            INTEGER,
   buffer      IN            RAW);

DBMS_LOB.FRAGMENT_INSERT (
   lob_loc     IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,
   amount      IN            INTEGER,
   offset      IN            INTEGER,
   buffer      IN            VARCHAR2 CHARACTER SET lob_loc%CHARSET);
```

Parameters

Table 104-47 FRAGMENT_INSERT Procedure Parameters

Parameter	Description
lob_loc	LOB locator.For more information, see Operational Notes.
amount	Number of bytes (BLOB) or characters (CLOB/NCLOB) to be inserted into the LOB
offset	Offset into the LOB in bytes (BLOB) or characters (CLOB/NCLOB) to begin the insertion
buffer	Data to insert into the LOB

Exceptions

Table 104-48 FRAGMENT_INSERT Procedure Exceptions

Exception	Description
INVALID_ARGVAL	A parameter value was invalid
QUERY_WRITE	Cannot perform operation during a query
SECUREFILE_BADLOB	A non-SECUREFILE LOB was used in a SECUREFILE LOB only call

Table 104-48 (Cont.) FRAGMENT_INSERT Procedure Exceptions

Exception	Description
SECUREFILE_OUTOFBOUNDS	Attempted to perform a FRAGMENT_* operation past LOB end

Usage Notes

FRAGMENT_INSERT gets the LOB, if necessary, before performing operations on the LOB.

104.8.21 FRAGMENT_MOVE Procedure

This procedure moves the amount of bytes (BLOB) or characters (CLOB/NCLOB) from the specified offset to the new offset specified.

Syntax

```
DBMS_LOB.FRAGMENT_MOVE (
   lob_loc       IN OUT NOCOPY BLOB,
   amount        IN            INTEGER,
   src_offset    IN            INTEGER,
   dest_offset   IN            INTEGER);

DBMS_LOB.FRAGMENT_MOVE (
   lob_loc       IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,
   amount        IN            INTEGER,
   src_offset    IN            INTEGER,
   dest_offset   IN            INTEGER);
```

Parameters

Table 104-49 FRAGMENT_MOVE Procedure Parameters

Parameter	Description
lob_loc	LOB locator. For more information, see Operational Notes.
amount	Number of bytes (BLOB) or characters (CLOB/NCLOB) to be moved in the LOB
src_offset	Beginning offset into the LOB in bytes (BLOB) or characters (CLOB/NCLOB) to put the data
dest_offset	Beginning offset into the LOB in bytes (BLOB) or characters (CLOB/NCLOB) to remove the data

Exceptions

Table 104-50 FRAGMENT_MOVE Procedure Exceptions

Exception	Description
INVALID_ARGVAL	A parameter value was invalid
QUERY_WRITE	Cannot perform operation during a query

Table 104-50 (Cont.) FRAGMENT_MOVE Procedure Exceptions

Exception	Description
SECUREFILE_BADLOB	A non-SECUREFILE LOB was used in a SECUREFILE LOB only call
SECUREFILE_OUTOFBOUNDS	Attempted to perform a FRAGMENT_* operation past LOB end

Usage Notes

- All offsets are pre-move offsets.
- Offsets of more than 1 past the end of the LOB are not permitted.
- FRAGMENT_MOVE gets the LOB, if necessary, before performing operations on the LOB.

104.8.22 FRAGMENT_REPLACE Procedures

This procedure replaces the data at the specified offset with the specified data (not to exceed 32k).

Syntax

```
DBMS_LOB.FRAGMENT_REPLACE (
   lob_loc     IN OUT NOCOPY BLOB,
   old_amount  IN            INTEGER,
   new_amount  IN            INTEGER,
   offset      IN            INTEGER,
   buffer      IN            RAW);

DBMS_LOB.FRAGMENT_REPLACE (
   lob_loc     IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,   old_amount  IN
INTEGER,
   new_amount  IN           INTEGER,
   offset      IN           INTEGER,
   buffer      IN           VARCHAR2 CHARACTER SET lob_loc%CHARSET);
```

Parameters

Table 104-51 FRAGMENT_REPLACE Function Parameters

Parameter	Description
lob_loc	LOB locator. For more information, see Operational Notes.
old_amount	Number of bytes (BLOB) or characters (CLOB/NCLOB) to be replaced in the LOB
new_amount	Number of bytes (BLOB) or characters (CLOB/NCLOB) to written to the LOB
offset	Beginning offset into the LOB in bytes (BLOB) or characters (CLOB/NCLOB) to put the data
buffer	Data to insert into the LOB

Exceptions

Table 104-52 FRAGMENT_REPLACE Procedure Exceptions

Exception	Description
INVALID_ARGVAL	A parameter value was invalid
QUERY_WRITE	Cannot perform operation during a query
SECUREFILE_BADLOB	A non-SECUREFILE LOB was used in a SECUREFILE LOB only call
SECUREFILE_OUTOFBOUNDS	Attempted to perform a FRAGMENT_* operation past LOB end

Usage Notes

- Invoking this procedure is equivalent to deleting the old amount of bytes/characters at offset and then inserting the new amount of bytes/characters at offset.
- FRAGMENT_REPLACE gets the LOB, if necessary, before performing operations on the LOB.

104.8.23 FREETEMPORARY Procedures

This procedure frees the temporary BLOB or CLOB in the default temporary tablespace.

Syntax

```
DBMS_LOB.FREETEMPORARY (
   lob_loc  IN OUT  NOCOPY BLOB);

DBMS_LOB.FREETEMPORARY (
   lob_loc  IN OUT  NOCOPY CLOB CHARACTER SET ANY_CS);
```

Parameters

Table 104-53 FREETEMPORARY Procedure Parameters

Parameter	Description
lob_loc	LOB locator.For more information, see Operational Notes.

Usage Notes

- When a new temporary LOB is created, and there is currently no temporary LOB in use with the same duration (session, call), a new temporary LOB segment is created. When the temporary LOB is freed, the space it consumed is released to the temporary segment. If there are no other temporary LOBs for the same duration, the temporary segment is also freed.
- After the call to FREETEMPORARY, the LOB locator that was freed is marked as invalid.
- If an invalid LOB locator is assigned to another LOB locator using OCILobLocatorAssign in OCI or through an assignment operation in PL/SQL, then the target of the assignment is also freed and marked as invalid.

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.24 GET_DBFS_LINK Functions

This function returns the DBFS path name for the specified SecureFile LOB.

Syntax

```
DBMS_LOB.GET_DBFS_LINK (
  lob_loc             IN     BLOB,
  storage_path        OUT VARCHAR2(DBFS_LINK_PATH_MAX_SIZE),
  lob_length          OUT NUMBER);

DBMS_LOB.GET_DBFS_LINK (
  lob_loc             IN     CLOB CHARACTER SET ANY_CS,
  storage_path        OUT VARCHAR2(DBFS_LINK_PATH_MAX_SIZE),
  lob_length          OUT NUMBER);
```

Parameters

Table 104-54 GET_DBFS_LINK Function Parameters

Parameter	Description
lob_loc	LOB to be retrieved from DBFS
storage_path	Path where the LOB is stored in DBFS
lob_length	LOB length at the time of write to DBFS

Return Values

The Archive ID

Exceptions

Table 104-55 GET_DBFS_LINK Function Exceptions

Exception	Description
SECUREFILE_BADLOB	lob_loc is not a SECUREFILE
ORA-01555	The LOB has already been retrieved and has been modified since retrieval or the LOB has been migrated in and out (modified or not) since the locator was retrieved

104.8.25 GET_DBFS_LINK_STATE Procedures

GET_DBFS_LINK_STATE retrieves the current link state of the specified SecureFile.

Syntax

```
DBMS_LOB.GET_DBFS_LINK_STATE (
  lob_loc       IN BLOB,
  storage_path  OUT VARCHAR2(DBFS_LINK_PATH_MAX_SIZE),
  state         OUT NUMBER,
  cached        OUT BOOLEAN);

DBMS_LOB.GET_DBFS_LINK_STATE (
  lob_loc       IN CLOB CHARACTER SET ANY_CS,
  storage_path  OUT VARCHAR2(DBFS_LINK_PATH_MAX_SIZE),
  state         OUT NUMBER,
  cached        OUT BOOLEAN);
```

Parameters

Table 104-56 GET_DBFS_LINK_STATE Procedure Parameters

Parameter	Description
lob_loc	LOB to be retrieved from the archive
storage_path	Path where the LOB is stored in the DBFS HSM store
state	One of DBFS_LINK_NEVER, DBFS_LINK_NO or DBFS_LINK_YES
cached	If the LOB is archived and the data was specified to be cashed on put

Exceptions

Table 104-57 GET_DBFS_LINK_STATE Procedure Exceptions

Exception	Description
SECUREFILE_BADLOB	lob_loc is not a SECUREFILE

Usage Notes

- If the LOB has never been archived, state is set to DBMS_LOB.DBFS_LINK_NEVER. If the LOB has been archived, state is set to DBMS_LOB.DBFS_LINK_YES. If the LOB has been previously retrieved from the archive, state is set to DBFS_LINK_NO.
- If the LOB was archived, but the data was left in the RDBMS, cached is set to TRUE. If the data was removed after the link was created, cached is set to FALSE, and NULL if state is DBMS_LOB.DBFS_LINK_NEVER.

104.8.26 GETCONTENTTYPE Functions

This procedure returns the content type string previously set by means of the SETCONTENTTYPE Procedure.

Syntax

```
DBMS_LOB.GETCONTENTTYPE (
   lob_loc  IN BLOB)
 RETURN VARCHAR2;

DBMS_LOB.GETCONTENTTYPE (
   lob_loc  IN CLOB CHARACTER SET ANY_CS)
 RETURN VARCHAR2;
```

Pragmas

```
PRAGMA RESTRICT_REFERENCES(getcontenttype, WNDS, RNDS, WNPS, RNPS);
```

Parameters

Table 104-58 GETCONTENTTYPE Function Parameters

Parameter	Description
lob_loc	LOB whose content type is to be retrieved

Return Values

The returned content type.

If the SecureFiles LOB does not have a `contenttype` associated with it, `GETCONTENTTYPE()` returns `NULL`.

Exceptions

Table 104-59 GETCONTENTTYPE Function Exceptions

Exception	Description
SECUREFILE_BADLOB	lob_loc is not a SECUREFILE

Related Topics

- SETCONTENTTYPE Procedure
  This procedure sets the content type string for the data in the LOB.

104.8.27 GET_STORAGE_LIMIT Function

This function returns the LOB storage limit for the specified LOB.

Syntax

```
DBMS_LOB.GET_STORAGE_LIMIT (
   lob_loc  IN CLOB CHARACTER SET ANY_CS)
 RETURN INTEGER;
```

```
DBMS_LOB.GET_STORAGE_LIMIT (
   lob_loc  IN BLOB)
 RETURN INTEGER;
```

Pragmas

```
PRAGMA RESTRICT_REFERENCES(get_storage_limit, WNDS, RNDS, WNPS, RNPS);
```

Parameters

Table 104-60 GET_STORAGE_LIMIT Function Parameters

Parameter	Description
lob_loc	LOB locator. For more information, see Operational Notes.

Return Value

The value returned from this function is the maximum allowable size for specified LOB locator. For BLOBs, the return value depends on the block size of the tablespace the LOB resides in and is calculated as (2^{32})-1 (4294967295) times the block size of the tablespace. For CLOBs/NCLOBs, the value returned is the(2^{32})-1 (4294967295) times the block size of the tablespace divided by the character width of the CLOB/NCLOB.

Usage

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for details on LOB storage limits

104.8.28 GETCHUNKSIZE Functions

When creating the table, you can specify the chunking factor, a multiple of tablespace blocks in bytes. This corresponds to the chunk size used by the LOB data layer when accessing or modifying the LOB value. Part of the chunk is used to store system-related information, and the rest stores the LOB value. This function returns the amount of space used in the LOB chunk to store the LOB value.

Syntax

```
DBMS_LOB.GETCHUNKSIZE (
   lob_loc IN BLOB)
  RETURN INTEGER;

DBMS_LOB.GETCHUNKSIZE (
   lob_loc IN CLOB CHARACTER SET ANY_CS)
  RETURN INTEGER;
```

Pragmas

```
PRAGMA RESTRICT_REFERENCES(getchunksize, WNDS, RNDS, WNPS, RNPS);
```

Parameters

Table 104-61 GETCHUNKSIZE Function Parameters

Parameter	Description
lob_loc	LOB locator. For more information, see Operational Notes.

Return Values

The return value is a usable chunk size in bytes.

Usage Notes

- With regard to basic LOB files, performance is improved if you enter read/write requests using a multiple of this chunk size. For writes, there is an added benefit, because LOB chunks are versioned, and if all writes are done on a chunk basis, then no extra or excess versioning is done or duplicated. You could batch up the WRITE until you have enough for a chunk, instead of issuing several WRITE calls for the same chunk.

  These tactics of performance improvement do not apply to SecureFiles.
- Note that chunk size is independent of LOB type (BLOB, CLOB, NCLOB, Unicode or other character set).

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.29 GETLENGTH Functions

This function gets the length of the specified LOB. The length in bytes or characters is returned.

The length returned for a BFILE includes the EOF, if it exists. Any 0-byte or space filler in the LOB caused by previous ERASE or WRITE operations is also included in the length count. The length of an empty internal LOB is 0.

Syntax

```
DBMS_LOB.GETLENGTH (
   lob_loc    IN  BLOB)
  RETURN INTEGER;

DBMS_LOB.GETLENGTH (
   lob_loc    IN  CLOB   CHARACTER SET ANY_CS)
  RETURN INTEGER;

DBMS_LOB.GETLENGTH (
   file_loc    IN  BFILE)
  RETURN INTEGER;
```

Pragmas

```
pragma restrict_references(GETLENGTH, WNDS, WNPS, RNDS, RNPS);
```

Parameters

Table 104-62 GETLENGTH Function Parameter

Parameter	Description
file_loc	The file locator for the LOB whose length is to be returned.

Return Values

The length of the LOB in bytes or characters as an INTEGER. NULL is returned if the input LOB is NULL or if the input lob_loc is NULL. An error is returned in the following cases for BFILEs:

- lob_loc does not have the necessary directory and operating system privileges
- lob_loc cannot be read because of an operating system read error

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.30 GETOPTIONS Functions

This function obtains compression, deduplication, and encryption settings corresponding to the option_type field for a particular LOB.

Syntax

```
DBMS_LOB.GETOPTIONS (
   lob_loc             IN     BLOB,
   option_types        IN     PLS_INTEGER)
 RETURN PLS_INTEGER;

DBMS_LOB.GETOPTIONS (
  lob_loc             IN     CLOB CHARACTER SET ANY_CS,
  option_types        IN     PLS_INTEGER)
RETURN PLS_INTEGER;
```

Parameters

Table 104-63 GETOPTIONS Function Parameter

Parameter	Description
lob_loc	Locator for the LOB to be examined. For more information, see Operational Notes.
option_type	See Table 104-2

Return Values

The return values are a combination of COMPRESS_ON, ENCRYPT_ON and DEDUPLICATE_ON (see Table 104-3) depending on which option types (see Table 104-2) are passed in.

Exceptions

Table 104-64 GETOPTIONS Procedure Exceptions

Exception	Description
INVALID_ARGVAL	A parameter value was invalid
QUERY_WRITE	Cannot perform operation during a query
SECUREFILE_BADLOB	A non-SECUREFILE LOB was used in a SECUREFILE LOB only call

Usage Notes

You cannot turn compression or deduplication on or off for a SecureFile column that does not have those features on. The GetOptions Functions and SETOPTIONS Procedures work on individual SecureFiles. You can turn off a feature on a particular SecureFile and turn on a feature that has already been turned off by SetOptions, but you cannot turn on an option that has not been given to the SecureFile when the table was created.

104.8.31 INSTR Functions

This function returns the matching position of the *nth* occurrence of the pattern in the LOB, starting from the offset you specify.

Syntax

```
DBMS_LOB.INSTR (
   lob_loc    IN   BLOB,
   pattern    IN   RAW,
   offset     IN   INTEGER := 1,
   nth        IN   INTEGER := 1)
  RETURN INTEGER;

DBMS_LOB.INSTR (
   lob_loc    IN   CLOB      CHARACTER SET ANY_CS,
   pattern    IN   VARCHAR2  CHARACTER SET lob_loc%CHARSET,
   offset     IN   INTEGER := 1,
   nth        IN   INTEGER := 1)
  RETURN INTEGER;

DBMS_LOB.INSTR (
   file_loc   IN   BFILE,
   pattern    IN   RAW,
   offset     IN   INTEGER := 1,
   nth        IN   INTEGER := 1)
  RETURN INTEGER;
```

Pragmas

```
pragma restrict_references(INSTR, WNDS, WNPS, RNDS, RNPS);
```

Parameters

Table 104-65 INSTR Function Parameters

Parameter	Description
lob_loc	Locator for the LOB to be examined. For more information, see Operational Notes.
file_loc	The file locator for the LOB to be examined.
pattern	Pattern to be tested for. The pattern is a group of RAW bytes for BLOBs, and a character string (VARCHAR2) for CLOBs.The maximum size of the pattern is 16383 bytes.
offset	Absolute offset in bytes (BLOBs) or characters (CLOBs) at which the pattern matching is to start. (origin: 1)
nth	Occurrence number, starting at 1.

Return Values

Table 104-66 INSTR Function Return Values

Return	Description
INTEGER	Offset of the start of the matched pattern, in bytes or characters. It returns 0 if the pattern is not found.
NULL	Either: -any one or more of the IN parameters was NULL or INVALID. -offset < 1 or offset > LOBMAXSIZE. -nth < 1. -nth > LOBMAXSIZE.

Usage Notes

The form of the VARCHAR2 buffer (the pattern parameter) must match the form of the CLOB parameter. In other words, if the input LOB parameter is of type NCLOB, then the buffer must contain NCHAR data. Conversely, if the input LOB parameter is of type CLOB, then the buffer must contain CHAR data.

For BFILEs, the file must be already opened using a successful FILEOPEN operation for this operation to succeed.

Operations that accept RAW or VARCHAR2 parameters for pattern matching, such as INSTR, do not support regular expressions or special matching characters (as in the case of SQL LIKE) in the pattern parameter or substrings.

Exceptions

Table 104-67 INSTR Function Exceptions for BFILES

Exception	Description
UNOPENED_FILE	File was not opened using the input locator.

Table 104-67 (Cont.) INSTR Function Exceptions for BFILES

Exception	Description
NOEXIST_DIRECTORY	Directory does not exist.
NOPRIV_DIRECTORY	You do not have privileges for the directory.
INVALID_DIRECTORY	Directory has been invalidated after the file was opened.
INVALID_OPERATION	File does not exist, or you do not have access privileges on the file.

See Also:

- "SUBSTR Functions"
- *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.32 ISOPEN Functions

This function checks to see if the LOB was already opened using the input locator. This subprogram is for internal and external LOBs.

Syntax

```
DBMS_LOB.ISOPEN (
   lob_loc IN BLOB)
  RETURN INTEGER;

DBMS_LOB.ISOPEN (
   lob_loc IN CLOB CHARACTER SET ANY_CS)
  RETURN INTEGER;

DBMS_LOB.ISOPEN (
   file_loc IN BFILE)
  RETURN INTEGER;
```

Pragmas

```
PRAGMA RESTRICT_REFERENCES(isopen, WNDS, RNDS, WNPS, RNPS);
```

Parameters

Table 104-68 ISOPEN Function Parameters

Parameter	Description
lob_loc	LOB locator. For more information, see Operational Notes.
file_loc	File locator.

Return Values

The return value is 1 if the LOB is open, 0 otherwise.

Usage Notes

For BFILES, openness is associated with the locator. If the input locator was never passed to OPEN, the BFILE is not considered to be opened by this locator. However, a different locator may have opened the BFILE. More than one OPEN can be performed on the same BFILE using different locators.

For internal LOBs, openness is associated with the LOB, not with the locator. If locator1 opened the LOB, then locator2 also sees the LOB as open. For internal LOBs, ISOPEN requires a round-trip, because it checks the state on the server to see if the LOB is indeed open.

For external LOBs (BFILEs), ISOPEN also requires a round-trip, because that's where the state is kept.

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.33 ISREMOTE Function

This function checks to see if the LOB is local to the database or if it belongs to a remote database.

Syntax

```
DBMS_LOB.ISREMOTE (
   lob_loc IN BLOB)
  RETURN BOOLEAN;

DBMS_LOB.ISREMOTE (
   lob_loc IN CLOB CHARACTER SET ANY_CS)
  RETURN BOOLEAN;
```

Pragmas

```
PRAGMA RESTRICT_REFERENCES(isremote, WNDS, RNDS, WNPS, RNPS);
```

Parameters

Table 104-69 ISREMOTE Function Parameter

Parameter	Description
lob_loc	Locator for the LOB.

Return Values

BOOLEAN: TRUE for remote LOBs obtained over a database link; FALSE for LOBs obtained from local database

> **See Also:**
>
> - *Distributed LOBs* chapter in Database SecureFiles and Large Objects Developer's Guide for more details on the usage of this procedure.

104.8.34 ISSECUREFILE Function

This function returns `TRUE` if the LOB locator passed to it is for a SecureFile LOB. It returns `FALSE` otherwise.

Syntax

```
DBMS_LOB ISSECUREFILE(
    lob_loc    IN      BLOB)
  RETURN BOOLEAN;
```

Pragmas

```
PRAGMA RESTRICT_REFERENCES(issecurefile, WNDS, RNDS, WNPS, RNPS);
```

Parameters

Table 104-70 ISSECUREFILE Function Parameter

Parameter	Description
`lob_loc`	LOB locator. For more information, see Operational Notes.

Return Values

This function returns `TRUE` if the LOB locator passed to it is for a SecureFile LOB. It returns `FALSE` otherwise.

104.8.35 ISTEMPORARY Functions

This function determines whether a LOB instance is temporary.

Syntax

```
DBMS_LOB.ISTEMPORARY (
   lob_loc IN BLOB)
  RETURN INTEGER;

DBMS_LOB.ISTEMPORARY (
   lob_loc IN CLOB CHARACTER SET ANY_CS)
  RETURN INTEGER;
```

Pragmas

```
PRAGMA RESTRICT_REFERENCES(istemporary, WNDS, RNDS, WNPS, RNPS);
```

Parameters

Table 104-71 ISTEMPORARY Procedure Parameters

Parameter	Description
lob_loc	LOB locator. For more information, see Operational Notes.

Return Values

The return value is 1 if the LOB is temporary and exists; 0 if the LOB is not temporary or does not exist; NULL if the given locator is NULL.

Usage Notes

When you free a Temporary LOB with FREETEMPORARY, the LOB locator is not set to NULL. Consequently, ISTEMPORARY will return 0 for a locator that has been freed but not explicitly reset to NULL.

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.36 LOADBLOBFROMFILE Procedure

This procedure loads data from BFILE to internal BLOB. This achieves the same outcome as LOADFROMFILE, and returns the new offsets.

Syntax

```
DBMS_LOB.LOADBLOBFROMFILE (
   dest_lob    IN OUT NOCOPY BLOB,
   src_bfile   IN            BFILE,
   amount      IN            INTEGER,
   dest_offset IN OUT        INTEGER,
   src_offset  IN OUT        INTEGER);
```

Parameters

Table 104-72 LOADBLOBFROMFILE Procedure Parameters

Parameter	Description
dest_lob	BLOB locator of the target for the load.
src_bfile	BFILE locator of the source for the load.
amount	Number of bytes to load from the BFILE. You can also use DBMS_LOB.LOBMAXSIZE to load until the end of the BFILE.

Table 104-72 (Cont.) LOADBLOBFROMFILE Procedure Parameters

Parameter	Description
dest_offset	(IN) Offset in bytes in the destination BLOB (origin: 1) for the start of the write. (OUT) New offset in bytes in the destination BLOB right after the end of this write, which is also where the next write should begin.
src_offset	(IN) Offset in bytes in the source BFILE (origin: 1) for the start of the read.(OUT) Offset in bytes in the source BFILE right after the end of this read, which is also where the next read should begin.

Usage Notes

- You can specify the offsets for both the source and destination LOBs, and the number of bytes to copy from the source BFILE. The amount and src_offset, because they refer to the BFILE, are in terms of bytes, and the dest_offset is in bytes for BLOBs.
- If the offset you specify in the destination LOB is beyond the end of the data currently in this LOB, then zero-byte fillers or spaces are inserted in the destination BLOB. If the offset is less than the current length of the destination LOB, then existing data is overwritten.
- There is an error if the input amount plus offset exceeds the length of the data in the BFILE (unless the amount specified is LOBMAXSIZE which you can specify to continue loading until the end of the BFILE is reached).
- It is not mandatory that you wrap the LOB operation inside the OPEN/CLOSE operations. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.
- If you do not wrap the LOB operation inside the OPEN/CLOSE, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the OPEN or CLOSE statement.
- LOADFROMFILE gets the destination LOB prior to the load unless the load covers the entire LOB.

Constants and Defaults

There is no easy way to omit parameters. You must either declare a variable for IN/OUT parameter or provide a default value for the IN parameter. Here is a summary of the constants and the defaults that can be used.

Table 104-73 Suggested Values of the Parameter

Parameter	Default Value	Description
amount	DBMS_LOB.LOBMAXSIZE (IN)	Load the entire file
dest_offset	1 (IN)	start from the beginning
src_offset	1 (IN)	start from the beginning

Constants defined in DBMSLOB.SQL

```
lobmaxsize                      CONSTANT INTEGER        := DBMS_LOB.LOBMAXSIZE;
```

Exceptions

Table 104-74 LOADBLOBFROMFILE Procedure Exceptions

Exception	Description
VALUE_ERROR	Any of the input parameters are NULL or INVALID.
INVALID_ARGVAL	Either: - src_offset or dest_offset < 1. - src_offset or dest_offset > LOBMAXSIZE. - amount < 1. - amount > LOBMAXSIZE.

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.37 LOADCLOBFROMFILE Procedure

This procedure loads data from a BFILE to an internal CLOB/NCLOB with necessary character set conversion and returns the new offsets.

Syntax

```
DBMS_LOB.LOADCLOBFROMFILE (
   dest_lob       IN OUT NOCOPY   NOCOPY CLOB CHARACTER SET ANY_CS,
   src_bfile      IN              BFILE,
   amount         IN              INTEGER,
   dest_offset    IN OUT          INTEGER,
   src_offset     IN OUT          INTEGER,
   bfile_csid     IN              NUMBER,
   lang_context   IN OUT          INTEGER,
   warning        OUT             INTEGER);
```

Parameters

Table 104-75 LOADCLOBFROMFILE Procedure Parameters

Parameter	Description
dest_lob	CLOB/NCLOB locator of the target for the load.
src_bfile	BFILE locator of the source for the load.
amount	Number of bytes to load from the BFILE. Use DBMS_LOB.LOBMAXSIZE of load until the end of the BFILE.

Table 104-75 (Cont.) LOADCLOBFROMFILE Procedure Parameters

Parameter	Description
dest_offset	(IN) Offset in characters in the destination CLOB (origin: 1) for the start of the write. (OUT) The new offset in characters right after the end of this load, which is also where the next load should start. It always points to the beginning of the first complete character after the end of load. If the last character is not complete, offset goes back to the beginning of the partial character.
src_offset	(IN) Offset in bytes in the source BFILE (origin: 1) for the start of the read.(OUT)Offset in bytes in the source BFILE right after the end of this read, which is also where the next read should begin.
bfile_csid	Character set id of the source (BFILE) file.
lang_context	(IN) Language context, such as shift status, for the current load. (OUT) The language context at the time when the current load stopped, and what the next load should be using if continuing loading from the same source. This information is returned to the user so that they can use it for the continuous load without losing or misinterpreting any source data. For the very first load or if do not care, simply use the default 0. The details of this language context is hidden from the user. One does not need to know what it is or what's in it in order to make the call
warning	(OUT) Warning message. This indicates something abnormal happened during the loading. It may or may not be caused by the user's mistake. The loading is completed as required, and it's up to the user to check the warning message. Currently, the only possible warning is the inconvertible character. This happens when the character in the source cannot be properly converted to a character in destination, and the default replacement character (for example, '?') is used in place. The message is defined the constant value DBMS_LOB.WARN_INCONVERTIBLE_CHAR.

Usage Notes

You can specify the offsets for both the source and destination LOBs, and the number of bytes to copy from the source BFILE. The amount and src_offset, because they refer to the BFILE, are in terms of bytes, and the dest_offset is in characters for CLOBs.

If the offset you specify in the destination LOB is beyond the end of the data currently in this LOB, then zero-byte fillers or spaces are inserted in the destination CLOB. If the offset is less than the current length of the destination LOB, then existing data is overwritten.

There is an error if the input amount plus offset exceeds the length of the data in the BFILE (unless the amount specified is LOBMAXSIZE which you can specify to continue loading until the end of the BFILE is reached).

Note the following requirements:

- The destination character set is always the same as the database character set in the case of CLOB and national character set in the case of NCLOB.
- csid=0 indicates the default behavior that uses database csid for CLOB and national csid for NCLOB in the place of source csid. Conversion is still necessary if it is of varying width

- It is not mandatory that you wrap the LOB operation inside the OPEN/CLOSE operations. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

  If you do not wrap the LOB operation inside the OPEN/CLOSE, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the OPEN or CLOSE statement.

The source BFILE can contain data in the Unicode character set. The Unicode standard defines many encoding schemes that provide mappings from Unicode characters to sequences of bytes. Table 104-76 lists Unicode encodings schemes supported by this subprogram.

Table 104-76 Supported Unicode Encoding Schemes

Encoding Scheme	Oracle Name	bfile_csid Value
UTF-8	AL32UTF8	873
UTF-16BE	AL16UTF16	2000
UTF-16LE	AL16UTF16LE	2002
CESU-8	UTF8	871
UTF-EBCDIC	UTFE	872
UTF-16	UTF16	1000

All three UTF-16 encoding schemes encode Unicode characters as 2-byte unsigned integers. Integers can be stored in big-endian or in little-endian byte order. The UTF-16BE encoding scheme defines big-endian data. The UTF-16LE scheme defines little-endian data. The UTF-16 scheme requires that the source BFILE contains the Byte Order Mark (BOM) character in the first two bytes to define the byte order. The BOM code is 0xFEFF. If the code is stored as {0xFE,0xFF}, the data is interpreted as big-endian. If it is stored as {0xFF,0xFE}, the data is interpreted as little-endian.

In UTF-8 and in CESU-8 encodings the Byte Order Mark is stored as {0xEF,0xBB,0xBF}. With any of the Unicode encodings, the corresponding BOM sequence at the beginning of the file is recognized and not loaded into the destination LOB.

Constants

Here is a summary of the constants and the suggested values that can be used.

Table 104-77 Suggested Values of the LOADCLOBFROMFILE Parameter

Parameter	Suggested Value	Description
amount	DBMS_LOB.LOBMAXSIZE (IN)	Load the entire file
dest_offset	1 (IN)	start from the beginning
src_offset	1 (IN)	start from the beginning
csid	0 (IN)	default csid, use destination csid
lang_context	0 (IN)	default language context

Table 104-77 (Cont.) Suggested Values of the LOADCLOBFROMFILE Parameter

Parameter	Suggested Value	Description
warning	0 (OUT)	no warning message, everything is ok

Constants defined in DBMSLOB.SQL

```
lobmaxsize                  CONSTANT INTEGER       := 18446744073709551615;
warn_inconvertible_char     CONSTANT INTEGER       := 1;
default_csid                CONSTANT INTEGER       := 0;
default_lang_ctx            CONSTANT INTEGER       := 0;
no_warning                  CONSTANT INTEGER       := 0;
```

Exceptions

Table 104-78 LOADCLOBFROMFILE Procedure Exceptions

Exception	Description
VALUE_ERROR	Any of the input parameters are NULL or INVALID.
INVALID_ARGVAL	Either: - src_offset or dest_offset < 1. - src_offset or dest_offset > LOBMAXSIZE. - amount < 1. - amount > LOBMAXSIZE.

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.38 MOVE_TO_DBFS_LINK Procedures

This procedure archives the specified LOB data (from the database) into the DBFS HSM Store.

Syntax

```
DBMS_LOB.MOVE_TO_DBFS_LINK (
  lob_loc       IN OUT BLOB,
  storage_path  IN     VARCHAR2(dbfs_link_path_max_size),
  flags         IN     BINARY INTEGER DEFAULT DBFS_LINK_NOCACHE);

DBMS_LOB.MOVE_TO_DBFS_LINK (
  lob_loc       IN OUT CLOB CHARACTER SET ANY_CS,
  storage_path  IN     VARCHAR2(dbfs_link_path_max_size),
  flags         IN     BINARY INTEGER DEFAULT DBFS_LINK_NOCACHE);
```

Parameters

Table 104-79 MOVE_TO_DBFS_LINK Procedure Parameters

Parameter	Description
lob_loc	LOB to be archived
storage_path	Path where the LOB will be stored
flags	Either DBFS_LINK_CACHE or DBFS_LINK_NOCACHE. If DBFS_LINK_CACHE is specified, the LOB data continues to be stored in the RDBMS as well as being written to the DBFS store. DBFS_LINK_NOCACHE specifies that the LOB data should be deleted from the RDBMS once written to the DBFS.

Exceptions

Table 104-80 MOVE_TO_DBFS_LINK Procedure Exceptions

Exception	Description
SECUREFILE_BADLOB	lob_loc is not a SECUREFILE

Usage Notes

- If the LOB is already archived, the procedure silently returns as if the put was successful. In that case, if DBFS_LINK_NOCACHE is specified, or flags is defaulted, the LOB data is removed from the RDBMS.
- Calling this procedure multiple times on the same LOB with the same flags has no effect.
- Calling the procedure on a LOB that is already archived causes the LOB to be cached (DBFS_LINK_CACHE) or removed (DBFS_LINK_NOCACHE) according to the flag setting.

104.8.39 OPEN Procedures

This procedure opens a LOB, internal or external, in the indicated mode. Valid modes include read-only, and read/write.

Syntax

```
DBMS_LOB.OPEN (
   lob_loc   IN OUT NOCOPY BLOB,
   open_mode IN            BINARY_INTEGER);

DBMS_LOB.OPEN (
   lob_loc   IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,
   open_mode IN            BINARY_INTEGER);

DBMS_LOB.OPEN (
   file_loc  IN OUT NOCOPY BFILE,
   open_mode IN            BINARY_INTEGER := file_readonly);
```

Parameters

Table 104-81 OPEN Procedure Parameters

Parameter	Description
`lob_loc`	LOB locator. For more information, see Operational Notes.
`open_mode`	Mode in which to open. For `BLOB` and `CLOB` types, the mode can be either: `LOB_READONLY` or `LOB_READWRITE`. For `BFILE` types, the mode must be `FILE_READONLY`.

Usage Notes

> **Note:**
>
> If the LOB was opened in read-only mode, and if you try to write to the LOB, then an error is returned. `BFILE` can only be opened with read-only mode.

`OPEN` requires a round-trip to the server for both internal and external LOBs. For internal LOBs, `OPEN` triggers other code that relies on the `OPEN` call. For external LOBs (`BFILE`s), `OPEN` requires a round-trip because the actual operating system file on the server side is being opened.

It is not mandatory that you wrap all LOB operations inside the Open/Close interfaces. However, if you open a LOB, you must close it before you commit the transaction; an error is produced if you do not. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

It is an error to commit the transaction before closing all opened LOBs that were opened by the transaction. When the error is returned, the openness of the open LOBs is discarded, but the transaction is successfully committed. Hence, all the changes made to the LOB and non-LOB data in the transaction are committed, but the domain and function-based indexes are not updated. If this happens, you should rebuild the functional and domain indexes on the LOB column.

> **See Also:**
>
> *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.40 READ Procedures

This procedure reads a piece of a LOB, and returns the specified amount into the `buffer` parameter, starting from an absolute offset from the beginning of the LOB.

The number of bytes or characters actually read is returned in the `amount` parameter. If the input `offset` points past the End of LOB, then `amount` is set to 0, and a `NO_DATA_FOUND` exception is raised.

Syntax

```
DBMS_LOB.READ (
   lob_loc   IN             BLOB,
   amount    IN OUT  NOCOPY INTEGER,
   offset    IN             INTEGER,
   buffer    OUT            RAW);

DBMS_LOB.READ (
   lob_loc   IN             CLOB CHARACTER SET ANY_CS,
   amount    IN OUT  NOCOPY INTEGER,
   offset    IN             INTEGER,
   buffer    OUT            VARCHAR2 CHARACTER SET lob_loc%CHARSET);

DBMS_LOB.READ (
   file_loc   IN             BFILE,
   amount    IN OUT   NOCOPY INTEGER,
   offset    IN             INTEGER,
   buffer    OUT            RAW);
```

Parameters

Table 104-82 READ Procedure Parameters

Parameter	Description
`lob_loc`	Locator for the LOB to be read. For more information, see Operational Notes.
`file_loc`	The file locator for the LOB to be examined.
`amount`	Number of bytes (for `BLOB`s) or characters (for `CLOB`s) to read, or number that were read.
`offset`	Offset in bytes (for `BLOB`s) or characters (for `CLOB`s) from the start of the LOB (origin: 1).
`buffer`	Output buffer for the read operation.

Exceptions

Table 104-83 lists exceptions that apply to any LOB instance. Table 104-84 lists exceptions that apply only to `BFILE`s.

Table 104-83 READ Procedure Exceptions

Exception	Description
`VALUE_ERROR`	Any of `lob_loc`, `amount`, or `offset` parameters are `NULL`.

Table 104-83 (Cont.) READ Procedure Exceptions

Exception	Description
INVALID_ARGVAL	Either: - amount < 1 - amount > 32767 bytes (or the character equivalent) - offset < 1 - offset > LOBMAXSIZE - amount is greater, in bytes or characters, than the capacity of buffer.
NO_DATA_FOUND	End of the LOB is reached, and there are no more bytes or characters to read from the LOB: amount has a value of 0.

Table 104-84 READ Procedure Exceptions for BFILEs

Exception	Description
UNOPENED_FILE	File is not opened using the input locator.
NOEXIST_DIRECTORY	Directory does not exist.
NOPRIV_DIRECTORY	You do not have privileges for the directory.
INVALID_DIRECTORY	Directory has been invalidated after the file was opened.
INVALID_OPERATION	File does not exist, or you do not have access privileges on the file.

Usage Notes

- The form of the VARCHAR2 buffer must match the form of the CLOB parameter. In other words, if the input LOB parameter is of type NCLOB, then the buffer must contain NCHAR data. Conversely, if the input LOB parameter is of type CLOB, then the buffer must contain CHAR data.
- When calling DBMS_LOB.READ from the client (for example, in a BEGIN/END block from within SQL*Plus), the returned buffer contains data in the client's character set. The database converts the LOB value from the server's character set to the client's character set before it returns the buffer to the user.
- READ gets the LOB, if necessary, before the read.
- If the LOB is a DBFS LINK, data is streamed from DBFS, if possible, otherwise an exception is thrown.

See Also:

Oracle Database SecureFiles and Large Objects Developer's Guide for additional details on usage of this procedure

104.8.41 SET_DBFS_LINK Procedures

This function links the specified SecureFile to the specified path name. It does not copy the data to the path.

Syntax

```
DBMS_LOB.SET_DBFS_LINK (
  lob_loc        IN OUT BLOB,
  archive_id     IN     RAW(1024));

DBMS_LOB.SET_DBFS_LINK(
  lob_loc_dst    IN OUT CLOB CHARACTER SET ANY_CS,
  archive_id     IN     RAW(1024));
```

Parameters

Table 104-85 SET_DBFS_LINK Procedure Parameters

Parameter	Description
lob_loc	LOB for which to store the reference value
archive_id	Archive ID as returned by calling either of the GET_DBFS_LINK Functions Functions

Exceptions

Table 104-86 SET_DBFS_LINK Procedure Exceptions

Exception	Description
SECUREFILE_BADLOB	lob_loc is not a SECUREFILE

104.8.42 SETCONTENTTYPE Procedure

This procedure sets the content type string for the data in the LOB.

Syntax

```
DBMS_LOB.SETCONTENTTYPE (
   lob_loc      IN OUT NOCOPY BLOB,
   contenttype  IN            VARCHAR2);

DBMS_LOB.SETCONTENTTYPE (
   lob_loc     IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,
   contenttype IN            VARCHAR2);
```

Parameters

Table 104-87 SETCONTENTTYPE Procedure Parameters

Parameter	Description
lob_loc	LOB to be assigned the content type

Table 104-87 (Cont.) SETCONTENTTYPE Procedure Parameters

Parameter	Description
contenttype	String to be assigned

Exceptions

Table 104-88 SETCONTENTTYPE Procedure Exceptions

Exception	Description
SECUREFILE_BADLOB	lob_loc is not a SECUREFILE

Usage Notes

To clear an existing content type associated with a SECUREFILE, invoke SETCONTENTTYPE with contenttype set to empty string.

104.8.43 SETOPTIONS Procedures

This procedure enables/disables compression and deduplication on a per-LOB basis, overriding the default LOB column settings.

Syntax

```
DBMS_LOB.SETOPTIONS (
   lob_loc             IN     BLOB,
   option_types        IN     PLS_INTEGER,
   options             IN     PLS_INTEGER);

DBMS_LOB.SETOPTIONS (
  lob_loc             IN     CLOB CHARACTER SET ANY_CS,
  option_types        IN     PLS_INTEGER,
  options             IN     PLS_INTEGER);
```

Parameters

Table 104-89 SETOPTIONS Procedure Parameter

Parameter	Description
lob_loc	Locator for the LOB to be examined. For more information, see Operational Notes.
option_type	See Table 104-2
options	See Table 104-3

Exceptions

Table 104-90 SETOPTIONS Procedure Exceptions

Exception	Description
SECUREFILE_BADLOB	Unsupported object type for the operation
INVALID_ARGVAL	A parameter value was invalid
QUERY_WRITE	Cannot perform operation during a query

Usage Notes

- DBMS_LOB.SETOPTIONS cannot be used to enable or disable encryption on individual LOBs.
- You cannot turn the compression or deduplication features on or off for a SecureFile column if they were not turned when the table was created.

  The GETOPTIONS Functions and SETOPTIONS Procedures work on individual SecureFiles. You can turn off compression or deduplication on a particular SecureFiles LOB and turn on them on, *if* they have already been turned off by SETOPTIONS.
- This call incurs a round-trip to the server to make the changes persistent.

104.8.44 SUBSTR Functions

This function returns amount bytes or characters of a LOB, starting from an absolute offset from the beginning of the LOB.

For fixed-width n-byte CLOBs, if the input amount for SUBSTR is greater than (32767/n), then SUBSTR returns a character buffer of length (32767/n), or the length of the CLOB, whichever is lesser. For CLOBs in a varying-width character set, n is the maximum byte-width used for characters in the CLOB.

Syntax

```
DBMS_LOB.SUBSTR (
   lob_loc     IN    BLOB,
   amount      IN    INTEGER := 32767,
   offset      IN    INTEGER := 1)
  RETURN RAW;

DBMS_LOB.SUBSTR (
   lob_loc     IN    CLOB   CHARACTER SET ANY_CS,
   amount      IN    INTEGER := 32767,
   offset      IN    INTEGER := 1)
  RETURN VARCHAR2 CHARACTER SET lob_loc%CHARSET;

DBMS_LOB.SUBSTR (
   file_loc     IN    BFILE,
   amount      IN    INTEGER := 32767,
   offset      IN    INTEGER := 1)
  RETURN RAW;
```

Pragmas

```
pragma restrict_references(SUBSTR, WNDS, WNPS, RNDS, RNPS);
```

Parameters

Table 104-91 SUBSTR Function Parameters

Parameter	Description
lob_loc	Locator for the LOB to be read. For more information, see Operational Notes.
file_loc	The file locator for the LOB to be examined.
amount	Number of bytes (for BLOBs) or characters (for CLOBs) to be read.
offset	Offset in bytes (for BLOBs) or characters (for CLOBs) from the start of the LOB (origin: 1).

Return Values

Table 104-92 SUBSTR Function Return Values

Return	Description
RAW	Function overloading that has a BLOB or BFILE in parameter.
VARCHAR2	CLOB version.
NULL	Either: - any input parameter is NULL - amount < 1 - amount > 32767 - offset < 1 - offset > LOBMAXSIZE

Exceptions

Table 104-93 SUBSTR Function Exceptions for BFILE operations

Exception	Description
UNOPENED_FILE	File is not opened using the input locator.
NOEXIST_DIRECTORY	Directory does not exist.
NOPRIV_DIRECTORY	You do not have privileges for the directory.
INVALID_DIRECTORY	Directory has been invalidated after the file was opened.
INVALID_OPERATION	File does not exist, or you do not have access privileges on the file.

Usage Notes

- The form of the VARCHAR2 buffer must match the form of the CLOB parameter. In other words, if the input LOB parameter is of type NCLOB, then the buffer must contain NCHAR data. Conversely, if the input LOB parameter is of type CLOB, then the buffer must contain CHAR data.

- When calling DBMS_LOB.SUBSTR from the client (for example, in a BEGIN/END block from within SQL*Plus), the returned buffer contains data in the client's character set. The database converts the LOB value from the server's character set to the client's character set before it returns the buffer to the user.
- DBMS_LOB.SUBSTR will return 8191 or more characters based on the characters stored in the LOBs. If all characters are not returned as a consequence of the character byte size exceeding the available buffer, the user should either call DBMS_LOB.SUBSTR with a new offset to read the remaining characters, or call the subprogram on loop until all the data is extracted.
- SUBSTR gets the LOB, if necessary, before read.
- If the LOB is a DBFS Link, the data is streamed from DBFS, if possible, otherwise, an exception is thrown.

See Also:

- "INSTR Functions"
- "READ Procedures"
- *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.45 TRIM Procedures

This procedure trims the value of the internal LOB to the length you specify in the newlen parameter.

Specify the length in bytes for BLOBs, and specify the length in characters for CLOBs.

Note:

The TRIM procedure decreases the length of the LOB to the value specified in the newlen parameter.

If you attempt to TRIM an empty LOB, then nothing occurs, and TRIM returns no error. If the new length that you specify in newlen is greater than the size of the LOB, then an exception is raised.

Syntax

```
DBMS_LOB.TRIM (
   lob_loc        IN OUT  NOCOPY BLOB,
   newlen         IN             INTEGER);

DBMS_LOB.TRIM (
   lob_loc        IN OUT  NOCOPY CLOB CHARACTER SET ANY_CS,
   newlen         IN             INTEGER);
```

Parameters

Table 104-94 TRIM Procedure Parameters

Parameter	Description
lob_loc	Locator for the internal LOB whose length is to be trimmed. For more information, see Operational Notes.
newlen	New, trimmed length of the LOB value in bytes for BLOBs or characters for CLOBs.

Exceptions

Table 104-95 TRIM Procedure Exceptions

Exception	Description
VALUE_ERROR	lob_loc is NULL.
INVALID_ARGVAL	Either: - new_len < 0 - new_len > LOBMAXSIZE
QUERY_WRITE	Cannot perform a LOB write inside a query or PDML parallel execution server

Usage Notes

- It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.
- If you do not wrap the LOB operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the OPEN or CLOSE statement.
- TRIM gets the LOB, if necessary, before altering the length of the LOB, unless the new length specified is '0'

See Also:

- "ERASE Procedures"
- "WRITEAPPEND Procedures"
- *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.46 WRITE Procedures

This procedure writes a specified amount of data into an internal LOB, starting from an absolute offset from the beginning of the LOB. The data is written from the `buffer` parameter.

`WRITE` replaces (overwrites) any data that already exists in the LOB at the offset, for the length you specify.

Syntax

```
DBMS_LOB.WRITE (
   lob_loc  IN OUT NOCOPY  BLOB,
   amount   IN             INTEGER,
   offset   IN             INTEGER,
   buffer   IN             RAW);

DBMS_LOB.WRITE (
   lob_loc  IN OUT  NOCOPY CLOB   CHARACTER SET ANY_CS,
   amount   IN             INTEGER,
   offset   IN             INTEGER,
   buffer   IN             VARCHAR2 CHARACTER SET lob_loc%CHARSET);
```

Parameters

Table 104-96 WRITE Procedure Parameters

Parameter	Description
`lob_loc`	Locator for the internal LOB to be written to. For more information, see Operational Notes
`amount`	Number of bytes (for `BLOB`s) or characters (for `CLOB`s) to write
`offset`	Offset in bytes (for `BLOB`s) or characters (for `CLOB`s) from the start of the LOB (origin: 1) for the write operation.
`buffer`	Input buffer for the write

Exceptions

Table 104-97 WRITE Procedure Exceptions

Exception	Description
`VALUE_ERROR`	Any of `lob_loc`, `amount`, or `offset` parameters are `NULL`, out of range, or `INVALID`.
`INVALID_ARGVAL`	Either: - `amount < 1` - `amount > 32767 bytes (or the character equivalent)` - `offset < 1` - `offset > LOBMAXSIZE`
`QUERY_WRITE`	Cannot perform a LOB write inside a query or PDML parallel execution server

Table 104-97 (Cont.) WRITE Procedure Exceptions

Exception	Description
SECUREFILE_OUTOFBOUNDS	Attempted to perform a write operation past the end of a LOB having FRAGMENT_* on it

Usage Notes

- There is an error if the input amount is more than the data in the buffer. If the input amount is less than the data in the buffer, then only amount bytes or characters from the buffer is written to the LOB. If the offset you specify is beyond the end of the data currently in the LOB, then zero-byte fillers or spaces are inserted in the BLOB or CLOB respectively.
- The form of the VARCHAR2 buffer must match the form of the CLOB parameter. In other words, if the input LOB parameter is of type NCLOB, then the buffer must contain NCHAR data. Conversely, if the input LOB parameter is of type CLOB, then the buffer must contain CHAR data.
- When calling DBMS_LOB.WRITE from the client (for example, in a BEGIN/END block from within SQL*Plus), the buffer must contain data in the client's character set. The database converts the client-side buffer to the server's character set before it writes the buffer data to the LOB.
- It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.
- If you do not wrap the LOB operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the OPEN or CLOSE statement.
- WRITE gets the LOB, if necessary, before writing the LOB, unless the write is specified to overwrite the entire LOB.

See Also:

- "APPEND Procedures"
- "COPY Procedures"
- *Oracle Database SecureFiles and Large Objects Developer's Guide* for additional details on usage of this procedure

104.8.47 WRITEAPPEND Procedures

This procedure writes a specified amount of data to the end of an internal LOB. The data is written from the `buffer` parameter.

Syntax

```
DBMS_LOB.WRITEAPPEND (
   lob_loc IN OUT NOCOPY BLOB,
   amount  IN            INTEGER,
   buffer  IN            RAW);

DBMS_LOB.WRITEAPPEND (
   lob_loc IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,
   amount  IN            INTEGER,
   buffer  IN            VARCHAR2 CHARACTER SET lob_loc%CHARSET);
```

Parameters

Table 104-98 WRITEAPPEND Procedure Parameters

Parameter	Description
`lob_loc`	Locator for the internal LOB to be written to. For more information, see Operational Notes
`amount`	Number of bytes (for `BLOB`s) or characters (for `CLOB`s) to write
`buffer`	Input buffer for the write

Usage Notes

There is an error if the input amount is more than the data in the buffer. If the input amount is less than the data in the buffer, then only amount bytes or characters from the buffer are written to the end of the LOB.

Exceptions

Table 104-99 WRITEAPPEND Procedure Exceptions

Exception	Description
`VALUE_ERROR`	Any of `lob_loc`, `amount`, or `offset` parameters are `NULL`, out of range, or `INVALID`.
`INVALID_ARGVAL`	Either: - `amount` < `1` - `amount` > `32767 bytes (or the character equivalent)`
`QUERY_WRITE`	Cannot perform a LOB write inside a query or PDML parallel execution server

Usage Notes

- The form of the `VARCHAR2` buffer must match the form of the `CLOB` parameter. In other words, if the input LOB parameter is of type `NCLOB`, then the buffer must

contain NCHAR data. Conversely, if the input LOB parameter is of type CLOB, then the buffer must contain CHAR data.

- When calling DBMS_LOB.WRITEAPPEND from the client (for example, in a BEGIN/END block from within SQL*Plus), the buffer must contain data in the client's character set. The database converts the client-side buffer to the server's character set before it writes the buffer data to the LOB.
- It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.
- If you do not wrap the LOB operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the OPEN or CLOSE statement.
- WRITEAPPEND gets the LOB, if necessary, before appending to the LOB.

105
DBMS_LOCK

The DBMS_LOCK package provides an interface to Oracle Lock Management services.

You can request a lock of a specific mode, give it a unique name recognizable in another procedure in the same or another instance, change the lock mode, and release it.

This chapter contains the following topics:

- Overview
- Security Model
- Constants
- Rules and Limits
- Operational Notes
- Summary of DBMS_LOCK Subprograms

> **See Also:**
>
> For more information, and an example of how to use the DBMS_LOCK package, *Oracle Database Development Guide*

105.1 DBMS_LOCK Overview

The DBMS_LOCK package has many beneficial uses.

These uses include the following:

- Providing exclusive access to a device, such as a terminal
- Providing application-level enforcement of read locks
- Detecting when a lock is released and cleanup after the application
- Synchronizing applications and enforcing sequential processing

105.2 DBMS_LOCK Security Model

There might be operating system-specific limits on the maximum number of total locks available. This *must* be considered when using locks or making this package available to other users. Consider granting the EXECUTE privilege only to specific users or roles.

A better alternative would be to create a cover package limiting the number of locks used and grant EXECUTE privilege to specific users. An example of a cover package is documented in the DBMS_LOCK.SQL package specification file. The abbreviations for these locks as they appear in Enterprise Manager monitors are in parentheses.

105.3 DBMS_LOCK Constants

The DBMS_LOCK package includes several constants to use when specifying parameter values.

These constants are shown in the following table.

Table 105-1 DBMS_LOCK Constants

Name	Alternate Name(s)	Type	Value	OEM Abbreviation	Description
NL_MODE	NuL1	INTEGER	1	-	-
SS_MODE	Sub Shared	INTEGER	2	ULRS	This can be used on an aggregate object to indicate that share locks are being acquired on subparts of the object.
SX_MODE	• Sub eXclusive • Row Exclusive Mode	INTEGER	3	ULRX	This can be used on an aggregate object to indicate that exclusive locks are being acquired on sub-parts of the object.
S_MODE	• Shared • Row Exclusive Mode • Intended Exclusive	INTEGER	4	ULRSX	-
SSX_MODE	• Shared Sub eXclusive • Share Row Exclusive Mode	INTEGER	5	-	This indicates that the entire aggregate object has a share lock, but some of the sub-parts may additionally have exclusive locks.
X_MODE	Exclusive	INTEGER	6	ULX	-

These are the various lock modes (nl -> "NuLl", ss -> "Sub Shared", sx -> "Sub eXclusive", s -> "Shared", ssx -> "Shared Sub eXclusive", x -> "eXclusive").

105.4 DBMS_LOCK. Rules and Limits

When another process holds "held", an attempt to get "get" succeeds or fails, based on the held mode and type of get.

The following table describes the results:

Table 105-2 Lock Compatibility

HELD MODE	GET NL	GET SS	GET SX	GET S	GET SSX	GET X
NL	Success	Success	Success	Success	Success	Success
SS	Success	Success	Success	Success	Success	Fail

Table 105-2 (Cont.) Lock Compatibility

HELD MODE	GET NL	GET SS	GET SX	GET S	GET SSX	GET X
SX	Success	Success	Success	Fail	Fail	Fail
S	Success	Success	Fail	Success	Fail	Fail
SSX	Success	Success	Fail	Fail	Fail	Fail
X	Success	Fail	Fail	Fail	Fail	Fail

```
maxwait  constant integer := 32767;
```

The constant `maxwait` waits forever.

105.5 DBMS_LOCK Operational Notes

User locks never conflict with Oracle locks because they are identified with the prefix "UL". You can view these locks using the Enterprise Manager lock monitor screen or the appropriate fixed views.

User locks are automatically released when a session terminates. The lock identifier is a number in the range of 0 to 1073741823.

Because a reserved user lock is the same as an Oracle lock, it has all the functionality of an Oracle lock, such as deadlock detection. Be certain that any user locks used in distributed transactions are released upon `COMMIT`, or an undetected deadlock may occur.

`DBMS_LOCK` is most efficient with a limit of a few hundred locks for each session. Oracle strongly recommends that you develop a standard convention for using these locks in order to avoid conflicts among procedures trying to use the same locks. For example, include your company name as part of your lock names.

105.6 Summary of DBMS_LOCK Subprograms

This table lists the `DBMS_LOCK` subprograms and briefly describes them.

Table 105-3 *DBMS_LOCK Package Subprograms*

Subprogram	Description
ALLOCATE_UNIQUE Procedure	Allocates a unique lock ID to a named lock
ALLOCATE_UNIQUE_AUTONOMOUS Procedure	Allocates a unique lock ID to a named lock
CONVERT Function	Converts a lock from one mode to another
RELEASE Function	Releases a lock
REQUEST Function	Requests a lock of a specific mode.

105.6.1 ALLOCATE_UNIQUE Procedure

This procedure allocates a unique lock identifier (in the range of 1073741824 to 1999999999) a specified lock name. Lock identifiers are used to enable applications to coordinate their use

of locks. This is provided because it may be easier for applications to coordinate their use of locks based on lock names rather than lock numbers.

Syntax

```
DBMS_LOCK.ALLOCATE_UNIQUE (
   lockname         IN  VARCHAR2,
   lockhandle       OUT VARCHAR2,
   expiration_secs  IN  INTEGER   DEFAULT 864000);
```

Parameters

Table 105-4 ALLOCATE_UNIQUE Procedure Parameters

Parameter	Description
lockname	Name of the lock for which you want to generate a unique ID. Do not use lock names beginning with ORA$; these are reserved for products supplied by Oracle.
lockhandle	Returns the handle to the lock ID generated by ALLOCATE_UNIQUE. You can use this handle in subsequent calls to REQUEST, CONVERT, and RELEASE. A handle is returned instead of the actual lock ID to reduce the chance that a programming error accidentally creates an incorrect, but valid, lock ID. This provides better isolation between different applications that are using this package. LOCKHANDLE can be up to VARCHAR2 (128). All sessions using a lock handle returned by ALLOCATE_UNIQUE with the same lock name are referring to the same lock. Therefore, do not pass lock handles from one session to another.
expiration_specs	Number of seconds to wait after the last ALLOCATE_UNIQUE has been performed on a specified lock, before permitting that lock to be deleted from the DBMS_LOCK_ALLOCATED table. The default waiting period is 10 days. You should not delete locks from this table. Subsequent calls to ALLOCATE_UNIQUE may delete expired locks to recover space.

Usage Notes

If you choose to identify locks by name, you can use ALLOCATE_UNIQUE to generate a unique lock identification number for these named locks.

The first session to call ALLOCATE_UNIQUE with a new lock name causes a unique lock ID to be generated and stored in the dbms_lock_allocated table. Subsequent calls (usually by other sessions) return the lock ID previously generated.

A lock name is associated with the returned lock ID for at least expiration_secs (defaults to 10 days) past the last call to ALLOCATE_UNIQUE with the specified lock name. After this time, the row in the dbms_lock_allocated table for this lock name may be deleted in order to recover space. ALLOCATE_UNIQUE performs a commit.

> **WARNING:**
>
> Named user locks may be less efficient, because Oracle uses SQL to determine the lock associated with a specified name.

Exceptions

`ORA-20000`, `ORU-10003`: Unable to find or insert lock <`lockname`> into catalog `dbms_lock_allocated`.

105.6.2 ALLOCATE_UNIQUE_AUTONOMOUS Procedure

This procedure allocates a unique lock identifier (in the range of 1073741824 to 1999999999) a specified lock name and is an autonomous version of the `ALLOCATE_UNIQUE` procedure. This procedure works exactly same as that of `ALLOCATE_UNIQUE`, except that the procedure will run as an autonomous transaction. Therefore the commits in `ALLOCATE_UNIQUE_AUTONOMOUS` procedure will not affect the calling procedure. The `ALLOCATE_UNIQUE_AUTONOMOUS` procedure is implemented in DB 12.1 and later releases.

Syntax

```
DBMS_LOCK.ALLOCATE_UNIQUE_AUTONOMOUS (
   lockname         IN  VARCHAR2,
   lockhandle       OUT VARCHAR2,
   expiration_secs  IN  INTEGER   DEFAULT 864000);
```

Parameters

Table 105-5 ALLOCATE_UNIQUE_AUTONOMOUS Procedure Parameters

Parameter	Description
`lockname`	Name of the lock for which you want to generate a unique ID. Do not use lock names beginning with `ORA$`; these are reserved for products supplied by Oracle.
`lockhandle`	Returns the handle to the lock ID generated by `ALLOCATE_UNIQUE_AUTONOMOUS`. You can use this handle in subsequent calls to `REQUEST`, `CONVERT`, and `RELEASE`. A handle is returned instead of the actual lock ID to reduce the chance that a programming error accidentally creates an incorrect, but valid, lock ID. This provides better isolation between different applications that are using this package. `LOCKHANDLE` can be up to `VARCHAR2` (128). All sessions using a lock handle returned by `ALLOCATE_UNIQUE_AUTONOMOUS` with the same lock name are referring to the same lock. Therefore, do not pass lock handles from one session to another.

Table 105-5 (Cont.) ALLOCATE_UNIQUE_AUTONOMOUS Procedure Parameters

Parameter	Description
expiration_specs	Number of seconds to wait after the last ALLOCATE_UNIQUE_AUTONOMOUS has been performed on a specified lock, before permitting that lock to be deleted from the ALLOCATE_UNIQUE_AUTONOMOUS table. The default waiting period is 10 days. You should not delete locks from this table. Subsequent calls to ALLOCATE_UNIQUE_AUTONOMOUS may delete expired locks to recover space.

Usage Notes

If you choose to identify locks by name, you can use ALLOCATE_UNIQUE_AUTONOMOUS to generate a unique lock identification number for these named locks.

The first session to call ALLOCATE_UNIQUE_AUTONOMOUS with a new lock name causes a unique lock ID to be generated and stored in the dbms_lock_allocated table. Subsequent calls (usually by other sessions) return the lock ID previously generated.

A lock name is associated with the returned lock ID for at least expiration_secs (defaults to 10 days) past the last call to ALLOCATE_UNIQUE_AUTONOMOUS with the specified lock name. After this time, the row in the dbms_lock_allocated table for this lock name may be deleted in order to recover space. ALLOCATE_UNIQUE_AUTONOMOUS performs a commit.

> **WARNING:**
>
> Named user locks may be less efficient, because Oracle uses SQL to determine the lock associated with a specified name.

Exceptions

ORA-20000, ORU-10003: Unable to find or insert lock <lockname> into catalog dbms_lock_allocated.

105.6.3 CONVERT Function

This function converts a lock from one mode to another. CONVERT is an overloaded function that accepts either a user-defined lock identifier, or the lock handle returned by the ALLOCATE_UNIQUE procedure.

Syntax

```
DBMS_LOCK.CONVERT(
   id         IN INTEGER ||
   lockhandle IN VARCHAR2,
   lockmode   IN INTEGER,
   timeout    IN NUMBER DEFAULT MAXWAIT)
  RETURN INTEGER;
```

Parameters

Table 105-6 CONVERT Function Parameters

Parameter	Description
`id` or `lockhandle`	User assigned lock identifier, from 0 to 1073741823, or the lock handle, returned by `ALLOCATE_UNIQUE`, of the lock mode you want to change
`lockmode`	New mode that you want to assign to the specified lock. For the available modes and their associated integer identifiers, see Constants.
`timeout`	Number of seconds to continue trying to change the lock mode. If the lock cannot be converted within this time period, then the call returns a value of 1 (timeout).

Return Values

Table 105-7 CONVERT Function Return Values

Return Value	Description
`0`	Success
`1`	Timeout
`2`	Deadlock
`3`	Parameter error
`4`	Don't own lock specified by `id` or `lockhandle`
`5`	Illegal lock handle

105.6.4 RELEASE Function

This function explicitly releases a lock previously acquired using the `REQUEST` function.

Locks are automatically released at the end of a session. `RELEASE` is an overloaded function that accepts either a user-defined lock identifier, or the lock handle returned by the `ALLOCATE_UNIQUE` procedure.

Syntax

```
DBMS_LOCK.RELEASE (
   id         IN INTEGER)
  RETURN INTEGER;

DBMS_LOCK.RELEASE (
   lockhandle IN VARCHAR2)
  RETURN INTEGER;
```

Parameters

Table 105-8 RELEASE Function Parameter

Parameter	Description
`id` or `lockhandle`	User assigned lock identifier, from 0 to 1073741823, or the lock handle, returned by `ALLOCATE_UNIQUE`, of the lock mode you want to change

Return Values

Table 105-9 RELEASE Function Return Values

Return Value	Description
`0`	Success
`3`	Parameter error
`4`	Do not own lock specified by `id` or `lockhandle`
`5`	Illegal lock handle

105.6.5 REQUEST Function

This function requests a lock with a specified mode.

`REQUEST` is an overloaded function that accepts either a user-defined lock identifier, or the lock handle returned by the `ALLOCATE_UNIQUE` procedure.

Syntax

```
DBMS_LOCK.REQUEST(
   id                IN  INTEGER ||
   lockhandle        IN  VARCHAR2,
   lockmode          IN  INTEGER DEFAULT X_MODE,
   timeout           IN  INTEGER DEFAULT MAXWAIT,
   release_on_commit IN  BOOLEAN DEFAULT FALSE)
  RETURN INTEGER;
```

The current default values, such as `X_MODE` and `MAXWAIT`, are defined in the `DBMS_LOCK` package specification.

Parameters

Table 105-10 REQUEST Function Parameters

Parameter	Description
`id` or `lockhandle`	User assigned lock identifier, from 0 to 1073741823, or the lock handle, returned by `ALLOCATE_UNIQUE`, of the lock mode you want to change
`lockmode`	Mode that you are requesting for the lock. For the available modes and their associated integer identifiers, see Constants.

Table 105-10 (Cont.) REQUEST Function Parameters

Parameter	Description
`timeout`	Number of seconds to continue trying to grant the lock. If the lock cannot be granted within this time period, then the call returns a value of `1` (`timeout`).
`release_on_commit`	Set this parameter to `TRUE` to release the lock on commit or roll-back. Otherwise, the lock is held until it is explicitly released or until the end of the session.

Return Values

Table 105-11 REQUEST Function Return Values

Return Value	Description
`0`	Success
`1`	Timeout
`2`	Deadlock
`3`	Parameter error
`4`	Already own lock specified by `id` or `lockhandle`
`5`	Illegal lock handle

106
DBMS_LOGMNR

The DBMS_LOGMNR package, one of a set of LogMiner packages, contains the subprograms you use to initialize the LogMiner tool and to begin and end a LogMiner session.

> **Note:**
>
> The ability to create flat file dictionary dumps of pluggable databases (PDBs) is desupported in Oracle Database 21c.
>
> In previous releases, using a flat file dictionary was one means of mining the redo logs for the changes associated with a specific PDB whose data dictionary was contained within the flat file. This feature is now desupported. Starting with Oracle Database 21c, Oracle recommends that you call DBMS_LOGMNR.START_LOGMNR, and supply the system change number (SCN) or time range that you want to mine. The SCN or time range options of START_LOGMNR are enhanced to support mining of individual PDBs.

The CONTINUOUS_MINE functionality of the LogMiner package is obsolete. It was deprecated in Oracle Database 12c release 2 (12.2). There is no replacement functionality.

This chapter contains the following topics:

- Overview
- Security Model
- Constants
- Views
- Operational Notes
- Summary of DBMS_LOGMNR Subprograms

> **See Also:**
>
> *Oracle Database Utilities* for information regarding LogMiner.

106.1 DBMS_LOGMNR Overview

Oracle LogMiner, which is part of Oracle Database, enables you to query online and archived redo log files through a SQL interface. The `DBMS_LOGMNR` package provides the majority of the tools needed to start and stop LogMiner and specify the redo log files of interest.

All changes made to user data or to the database dictionary are recorded in the Oracle redo log files so that database recovery operations can be performed. You can take advantage of the data recorded in the redo log files to accomplish other tasks, such as:

- Pinpointing when a logical corruption to a database, such as errors made at the application level, may have begun
- Determining what actions you would have to take to perform fine-grained recovery at the transaction level.
- Performance tuning and capacity planning through trend analysis.
- Track any data manipulation language (DML) and data definition language (DDL) statements executed on the database, the order in which they were executed, and who executed them.

> **See Also:**
>
> DBMS_LOGMNR_D for information on the package subprograms that extract a LogMiner dictionary and re-create LogMiner tables in alternate tablespaces

106.2 DBMS_LOGMNR Security Model

You must have the `EXECUTE_CATALOG_ROLE` role to use the `DBMS_LOGMNR` package.

106.3 DBMS_LOGMNR Constants

The `DBMS_LOGMNR` package defines several enumerated constants for specifying parameter values. Enumerated constants must be prefixed with the package name, for example, `DBMS_LOGMNR.NEW`.

> **Note:**
>
> The `continuous_mine` option for the `dbms_logmnr.start_logmnr` package is desupported in Oracle Database 19c (19.1), and is no longer available.

The following table describes the constants for the `ADD_LOGFILE options` flag in the `DBMS_LOGMNR` package.

Table 106-1 Constants for ADD_LOGFILE Options Flag

Constant	Description
NEW	Implicitly calls the DBMS_LOGMNR.END_LOGMNR procedure to end the current LogMiner session and then creates a new session. The new session starts a new list of redo log files to be analyzed, beginning with the redo log file you specify.
ADDFILE	Adds the specified redo log file to the list of redo log files to be analyzed. Any attempt to add a duplicate file raises an exception (ORA-01289). This is the default if no options flag is specified.

Table 106-2 describes the constants for the START_LOGMNR options flag in the DBMS_LOGMNR package.

Table 106-2 Constants for START_LOGMNR Options Flag

Constant	Description
COMMITTED_DATA_ONLY	If set, DML statements corresponding to committed transactions are returned. DML statements corresponding to a committed transaction are grouped together. Transactions are returned in their commit order. Transactions that are rolled back or in-progress are filtered out, as are internal redo records (those related to index operations, management, and so on). If this option is not set, all rows for all transactions (committed, rolled back, and in-progress) are returned in the order in which they are found in the redo logs (in order of SCN values).
SKIP_CORRUPTION	Directs a select operation on the V$LOGMNR_CONTENTS view to skip any corruptions in the redo log file being analyzed and continue processing. This option works only when a block in the redo log file (and not the header of the redo log file) is corrupt. You should check the INFO column in the V$LOGMNR_CONTENTS view to determine the corrupt blocks skipped by LogMiner. When a corruption in the redo log file is skipped, the OPERATION column contains the value CORRUPTED_BLOCKS, and the STATUS column contains the value 1343.
DDL_DICT_TRACKING	If the LogMiner dictionary in use is a flat file or in the redo log files, LogMiner updates its internal dictionary if a DDL event occurs. This ensures that correct SQL_REDO and SQL_UNDO information is maintained for objects that are modified after the LogMiner internal dictionary is built. The database to which LogMiner is connected must be open. This option cannot be used in conjunction with the DICT_FROM_ONLINE_CATALOG option and cannot be used when the LogMiner dictionary being used is one that was extracted to a flat file prior to Oracle9*i*.

Table 106-2 (Cont.) Constants for START_LOGMNR Options Flag

Constant	Description
DICT_FROM_ONLINE_CATALOG	Directs LogMiner to use the current online database dictionary rather than a LogMiner dictionary contained in a flat file or in the redo log files being analyzed. This option cannot be used in conjunction with the DDL_DICT_TRACKING option. The database to which LogMiner is connected must be the same one that generated the redo log files. Expect to see a value of 2 in the STATUS column of the V$LOGMNR_CONTENTS view if the table definition in the database does not match the table definition in the redo log file.
DICT_FROM_REDO_LOGS	If set, LogMiner expects to find a LogMiner dictionary in the redo log files that were specified. The redo log files are specified with the DBMS_LOGMNR.ADD_LOGFILE procedure or with the DBMS_LOGMNR.START_LOGMNR procedure.
NO_SQL_DELIMITER	If set, the SQL delimiter (a semicolon) is not placed at the end of reconstructed SQL statements. This is helpful for applications that open a cursor and then execute the reconstructed statements.
NO_ROWID_IN_STMT	If set, the ROWID clause is not included in the reconstructed SQL statements. The redo log file may already contain logically unique identifiers for modified rows if supplemental logging is enabled. When using this option, you must be sure that supplemental logging was enabled in the source database at the appropriate level and that no duplicate rows exist in the tables of interest. LogMiner does not make any guarantee regarding the uniqueness of logical row identifiers.
PRINT_PRETTY_SQL	If set, LogMiner formats the reconstructed SQL statements for ease of reading. These reconstructed SQL statements are not executable.
STRING_LITERALS_IN_STMT	If set, SQL_REDO and SQL_UNDO use literals for numbers and datetime and interval column types.

To specify more than one option, use a plus sign (+) between them. For example:

```
EXECUTE DBMS_LOGMNR.START_LOGMNR(OPTIONS => -
   DBMS_LOGMNR.DDL_DICT_TRACKING + DBMS_LOGMNR.DICT_FROM_REDO_LOGS);
```

106.4 DBMS_LOGMNR Views

The DBMS_LOGMNR package uses the views listed under *Accessing Logminer Operational Information In Views* in *Oracle Database Utilities*.

> **See Also:**
>
> *Oracle Database Utilities*

106.5 DBMS_LOGMNR Operational Notes

A **LogMiner session** begins with a call to DBMS_LOGMNR.ADD_LOGFILE or DBMS_LOGMNR.START_LOGMNR (the former if you plan to specify log files explicitly; the

latter if you plan to use continuous mining). The session ends with a call to `DBMS_LOGMNR.END_LOGMNR`.

Within a LogMiner session, you can specify the redo log files to be analyzed and the SCN or time range of interest; then you can issue SQL `SELECT` statements against the `V$LOGMNR_CONTENTS` view to retrieve the data of interest.

`ADD_LOGFILE` Procedure must be invoked before `START_LOGMNR` Procedure.

> **Note:**
>
> You must add log files before filtering. Continuous logging is no longer supported. If logfiles have not been added that match the time or the SCN that you provide, then `DBMS_LOGMNR.START_LOGMNR` fails with the error `ORA-01291: missing logfile`.

106.6 Summary of DBMS_LOGMNR Subprograms

This table lists the `DBMS_LOGMNR` subprograms and briefly describes them.

In a multitenant container database (CDB) some subprograms must be called from the root. There may be other differences as well. See the individual subprogram descriptions for details.

Table 106-3 DBMS_LOGMNR Package Subprograms

Subprogram	Description
ADD_LOGFILE Procedure	Adds a redo log file to the existing or newly created list of redo log files for LogMiner to process, so that if a new list is created, this marks the beginning of a LogMiner session
COLUMN_PRESENT Function	Call this function for any row returned from the `V$LOGMNR_CONTENTS` view to determine if undo or redo column values exist for the column specified by the `column_name` input parameter to this function
END_LOGMNR Procedure	Finishes a LogMiner session
MINE_VALUE Function	Call this function for any row returned from the `V$LOGMNR_CONTENTS` view to retrieve the undo or redo column value of the column specified by the `column_name` input parameter to this function
REMOVE_LOGFILE Procedure	Removes a redo log file from the list of redo log files for LogMiner to process
START_LOGMNR Procedure	Initializes the LogMiner utility and starts LogMiner (unless the session was already started with a call to `DBMS_LOGMNR.ADD_LOGFILE`)

106.6.1 ADD_LOGFILE Procedure

This procedure adds a file to an existing or newly created list of log files for LogMiner to process.

> **Note:**
>
> The `continuous_mine` option for the `dbms_logmnr.start_logmnr` package is desupported in Oracle Database 19c (19.1), and is no longer available.

In a CDB, the `ADD_LOGFILE` procedure must be called from the root database. You must have the `LOGMINING` administrative privilege to use this procedure.

Syntax

```
DBMS_LOGMNR.ADD_LOGFILE (
   LogFileName     IN VARCHAR2,
   options         IN BINARY_INTEGER default ADDFILE );
```

Parameters

Table 106-4 ADD_LOGFILE Procedure Parameters

Parameter	Description
`LogFileName`	Specifies the name of the redo log file to add to the list of redo log files to be analyzed during this session.
`options`	Does one of the following: • Starts a new LogMiner session and a new list of redo log files for analysis (`DBMS_LOGMNR.NEW`) • Adds a file to an existing list of redo log files for analysis (`DBMS_LOGMNR.ADDFILE`) See Table 106-1.

Exceptions

Table 106-5 ADD_LOGFILE Procedure Exceptions

Exception	Description
`ORA-01284`	Specified file cannot be opened.
`ORA-01287`	Specified file is from a different database incarnation.
`ORA-01289`	Specified file has already been added to the list. Duplicate redo log files cannot be added.
`ORA-01290`	Specified file is not in the current list and therefore cannot be removed from the list.
`ORA-01324`	Specified file cannot be added to the list because there is a DB_ID mismatch.

Usage Notes

- The DBMS_LOGMNR.ADD_LOGFILE call from a PDB connection is not supported for adhoc users and returns error 65040.
- Dumping Flat File dictionary and mining using Flat File dictionary are not supported from a PDB connection.
- Before querying the V$LOGMNR_CONTENTS view, you must make a successful call to the DBMS_LOGMNR.START_LOGMNR procedure (within the current LogMiner session).
- The LogMiner session must be set up with a list of redo log files to be analyzed. Use the ADD_LOGFILE procedure to specify the list of redo log files to analyze.
- If you want to analyze more than one redo log file, you must call the ADD_LOGFILE procedure separately for each redo log file. The redo log files do not need to be registered in any particular order.
- Both archived and online redo log files can be mined.
- After you have added the first redo log file to the list, each additional redo log file that you add to the list must be associated with the same database and database RESETLOGS SCN as the first redo log file. (The database RESETLOGS SCN uniquely identifies each execution of an ALTER DATABASE OPEN RESETLOGS statement. When the online redo logs are reset, Oracle creates a new and unique incarnation of the database.)
- To analyze the redo log files from a different database (or a database incarnation with a different database RESETLOGS SCN) than that with which the current list of redo log files is associated, use the END_LOGMNR procedure to end the current LogMiner session, and then build a new list using the ADD_LOGFILE procedure.
- LogMiner matches redo log files by the log sequence number. Thus, two redo log files with different names but with the same log sequence number will return the ORA-01289 exception. For instance, the online counterpart of an archived redo log file has a different name from the archived redo log file, but attempting to register it with LogMiner after registering the archived counterpart will result in the ORA-01289 exception being returned.

106.6.2 COLUMN_PRESENT Function

This function is designed to be used in conjunction with the MINE_VALUE function.

If the MINE_VALUE function returns a NULL value, it can mean either:

- The specified column is not present in the redo or undo portion of the data.
- The specified column is present and has a NULL value.

To distinguish between these two cases, use the COLUMN_PRESENT function, which returns a 1 if the column is present in the redo or undo portion of the data. Otherwise, it returns a 0.

Syntax

```
DBMS_LOGMNR.COLUMN_PRESENT (
     sql_redo_undo      IN  RAW,
     column_name        IN  VARCHAR2 default '') RETURN NUMBER;
```

Parameters

Table 106-6 COLUMN_PRESENT Function Parameters

Parameter	Description
sql_redo_undo	Specifies either the REDO_VALUE or the UNDO_VALUE column in the V$LOGMNR_CONTENTS view from which to extract data values. See the Usage Notes for more information.
column_name	Specifies the fully qualified name (schema.table.column) of the column for which this function will return information. In a CDB, the column name is specified as follows: container_name:schema.table.column

Return Values

Table 106-7 describes the return values for the COLUMN_PRESENT function. The COLUMN_PRESENT function returns 1 if the self-describing record (the first parameter) contains the column specified in the second parameter. This can be used to determine the meaning of NULL values returned by the DBMS_LOGMNR.MINE_VALUE function.

Table 106-7 Return Values for COLUMN_PRESENT Function

Return	Description
0	Specified column is not present in this row of V$LOGMNR_CONTENTS.
1	Column is present in this row of V$LOGMNR_CONTENTS.

Exceptions

Table 106-8 COLUMN_PRESENT Function Exceptions

Exception	Description
ORA-01323	Currently, a LogMiner dictionary is not associated with the LogMiner session. You must specify a LogMiner dictionary for the LogMiner session.
ORA-00904	Value specified for the column_name parameter is not a fully qualified column name.

Usage Notes

- To use the COLUMN_PRESENT function, you must have successfully started LogMiner.
- The COLUMN_PRESENT function must be invoked in the context of a select operation on the V$LOGMNR_CONTENTS view.
- The COLUMN_PRESENT function does not support LONG, LOB, ADT, or COLLECTION datatypes.
- The value for the sql_redo_undo parameter depends on the operation performed and the data of interest:

- If an update operation was performed and you want to know what the value was prior to the update operation, specify UNDO_VALUE.
- If an update operation was performed and you want to know what the value is after the update operation, specify REDO_VALUE.
- If an insert operation was performed, typically you would specify REDO_VALUE (because the value of a column prior to an insert operation will always be NULL).
- If a delete operation was performed, typically you would specify UNDO_VALUE (because the value of a column after a delete operation will always be NULL).

106.6.3 END_LOGMNR Procedure

This procedure finishes a LogMiner session. Because this procedure performs cleanup operations that may not otherwise be done, you must use it to properly end a LogMiner session. This procedure is called automatically when you log out of a database session or when you call DBMS_LOGMNR.ADD_LOGFILE and specify the NEW option.

Syntax

```
DBMS_LOGMNR.END_LOGMNR;
```

Exceptions

Table 106-9 END_LOGMNR Procedure Exception

Exception	Description
ORA-01307	No LogMiner session is currently active. The END_LOGMNR procedure was called without adding any log files or before the START_LOGMNR procedure was called

106.6.4 MINE_VALUE Function

This function facilitates queries based on a column's data value.

This function takes two arguments. The first one specifies whether to mine the redo (REDO_VALUE) or undo (UNDO_VALUE) portion of the data. The second argument is a string that specifies the fully qualified name of the column to be mined. The MINE_VALUE function always returns a string that can be converted back to the original datatype.

Syntax

```
DBMS_LOGMNR.MINE_VALUE (
     sql_redo_undo      IN  RAW,
     column_name        IN  VARCHAR2 default '') RETURN VARCHAR2;
```

Parameters

Table 106-10 MINE_VALUE Function Parameters

Parameter	Description
sql_redo_undo	Specifies either the REDO_VALUE or the UNDO_VALUE column in the V$LOGMNR_CONTENTS view from which to extract data values. See the Usage Notes for more information.
column_name	Specifies the fully qualified name (schema.table.column) of the column for which this function will return information. In a CDB, the column name is specified as follows: container_name:schema.table.column

Return Values

Table 106-11 Return Values for MINE_VALUE Function

Return	Description
NULL	The column is not contained within the self-describing record, or the column value is NULL. To distinguish between the two different null possibilities, use the DBMS_LOGMNR.COLUMN_PRESENT function.
NON-NULL	The column is contained within the self-describing record; the value is returned in string format.

Exceptions

Table 106-12 MINE_VALUE Function Exceptions

Exception	Description
ORA-01323	Invalid state. Currently, a LogMiner dictionary is not associated with the LogMiner session. You must specify a LogMiner dictionary for the LogMiner session.
ORA-00904	Invalid identifier. The value specified for the column_name parameter was not a fully qualified column name.

Usage Notes

- To use the MINE_VALUE function, you must have successfully started LogMiner.
- The MINE_VALUE function must be invoked in the context of a select operation from the V$LOGMNR_CONTENTS view.
- The MINE_VALUE function does not support LONG, LOB, ADT, or COLLECTION datatypes.
- The value for the sql_redo_undo parameter depends on the operation performed and the data of interest:
  - If an update operation was performed and you want to know what the value was prior to the update operation, specify UNDO_VALUE.

  - If an update operation was performed and you want to know what the value is after the update operation, specify `REDO_VALUE`.
  - If an insert operation was performed, typically you would specify `REDO_VALUE` (because the value of a column prior to an insert operation will always be null).
  - If a delete operation was performed, typically you would specify `UNDO_VALUE` (because the value of a column after a delete operation will always be null).
- If the `DBMS_LOGMNR.MINE_VALUE` function is used to get an `NCHAR` value that includes characters not found in the database character set, then those characters are returned as the replacement character (for example, an inverted question mark) of the database character set.

106.6.5 REMOVE_LOGFILE Procedure

This procedure removes a redo log file from an existing list of redo log files for LogMiner to process.

In a CDB, the `REMOVE_LOGFILE` procedure must be called from the root database. You must have the `LOGMINING` administrative privilege to use this procedure.

Syntax

```
DBMS_LOGMNR.REMOVE_LOGFILE (
   LogFileName     IN VARCHAR2);
```

Parameters

Table 106-13 REMOVE_LOGFILE Procedure Parameters

Parameter	Description
`LogFileName`	Specifies the name of the redo log file to be removed from the list of redo log files to be analyzed during this session.

Exceptions

Table 106-14 REMOVE_LOGFILE Procedure Exception

Exception	Description
`ORA-01290`	Cannot remove unlisted log file

Usage Notes

- Before querying the `V$LOGMNR_CONTENTS` view, you must make a successful call to the `DBMS_LOGMNR.START_LOGMNR` procedure (within the current LogMiner session).
- You can use this procedure to remove a redo log file from the list of redo log files for LogMiner to process if you know that redo log file does not contain any data of interest.
- Multiple redo log files can be removed by calling this procedure repeatedly.
- The redo log files do not need to be removed in any particular order.
- To start a new list of redo log files for analysis, use the `END_LOGMNR` procedure to end the current LogMiner session, and then build a new list using the `ADD_LOGFILE` procedure.

- Even if you remove all redo log files from the list, any subsequent calls you make to the ADD_LOGFILE procedure must match the database ID and RESETLOGS SCN of the removed redo log files. Therefore, to analyze the redo log files from a different database (or a database incarnation with a different database RESETLOGS SCN) than that with which the current list of redo log files is associated, use the END_LOGMNR procedure to end the current LogMiner session, and then build a new list using the ADD_LOGFILE procedure.

106.6.6 START_LOGMNR Procedure

This procedure starts LogMiner by loading the dictionary that LogMiner will use to translate internal schema object identifiers to names.

In a CDB, the START_LOGMNR procedure must be called from the root database. You must have the LOGMINING administrative privilege to use this procedure.

> **Note:**
>
> The ability to create flat file dictionary dumps of pluggable databases (PDBs) is desupported in Oracle Database 21c.
>
> In previous releases, using a flat file dictionary was one means of mining the redo logs for the changes associated with a specific PDB whose data dictionary was contained within the flat file. This feature is now desupported. Starting with Oracle Database 21c, Oracle recommends that you call DBMS_LOGMNR.START_LOGMNR, and supply the system change number (SCN) or time range that you want to mine. The SCN or time range options of START_LOGMNR are enhanced to support mining of individual PDBs.

Syntax

```
DBMS_LOGMNR.START_LOGMNR (
   startScn           IN NUMBER default 0,
   endScn             IN NUMBER default 0,
   startTime          IN DATE default '01-jan-1988',
   endTime            IN DATE default '31-dec-2110',
   DictFileName       IN VARCHAR2 default '',
   Options            IN BINARY_INTEGER default 0 );
```

Parameters

Table 106-15 START_LOGMNR Procedure Parameters

Parameter	Description
startScn	Directs LogMiner to return only redo records with an SCN greater than or equal to the startScn specified. This fails if there is no redo log file containing the specified startScn value. (You can query the FILENAME, LOW_SCN, and NEXT_SCN columns in the V$LOGMNR_LOGS view for each redo log file to determine the range of SCN values contained in each redo log file.)

Table 106-15 (Cont.) START_LOGMNR Procedure Parameters

Parameter	Description
endScn	Directs LogMiner to return only redo records with an SCN less than or equal to the endScn specified. If you specify an endScn value that is beyond the value in any redo log file, then LogMiner uses the greatest endScn value in the redo log file that contains the most recent changes. (You can query the FILENAME, LOW_SCN, and NEXT_SCN columns in the V$LOGMNR_LOGS view for each redo log file to determine the range of SCN values contained in each redo log file.)
startTime	Directs LogMiner to return only redo records with a timestamp greater than or equal to the startTime specified. This fails if there is no redo log file containing the specified startTime value. (You can query the FILENAME, LOW_TIME, and HIGH_TIME columns in the V$LOGMNR_LOGS view for each redo log file to determine the range of time covered in each redo log file.) This parameter is ignored if startScn is specified. See the Usage Notes for additional information.
endTime	Directs LogMiner to return only redo records with a timestamp less than or equal to the endTime specified. If you specify an endTime value that is beyond the value in any redo log file, then LogMiner will use the greatest endTime in the redo log file that contains the most recent changes. You can query the FILENAME, LOW_TIME, and HIGH_TIME columns in the V$LOGMNR_LOGS view for each redo log file to determine the range of time covered in each redo log file.) This parameter is ignored if endScn is specified. See the Usage Notes for additional information.
DictFileName	Specifies the flat file that contains the LogMiner dictionary. It is used to reconstruct SQL_REDO and SQL_UNDO columns in V$LOGMNR_CONTENTS, as well as to fully translate SEG_NAME, SEG_OWNER, SEG_TYPE_NAME, TABLE_NAME, and TABLE_SPACE columns. The fully qualified path name for the LogMiner dictionary file must be specified. (This file must have been created previously through the DBMS_LOGMNR_D.BUILD procedure.) You need to specify this parameter only if neither DICT_FROM_REDO_LOGS nor DICT_FROM_ONLINE_CATALOG is specified.
options	See Table 106-2.

Exceptions

Table 106-16 START_LOGMNR Procedure Exceptions

Exception	Description
ORA-01280	Internal error encountered.
ORA-01281	startScn or endScn parameter value is not a valid SCN, or endScn is less than startScn.

Table 106-16 (Cont.) START_LOGMNR Procedure Exceptions

Exception	Description
ORA-01282	value for the startTime parameter was greater than the value specified for the endTime parameter, or there was no redo log file that was compatible with the date range specified with the startTime and endTime parameters.
ORA-01283	Options parameter specified is invalid.
ORA-01284	LogMiner dictionary file specified in the DictFileName parameter has a full path length greater than 256 characters, or the file cannot be opened.
ORA-01285	Error reading specified file.
ORA-01291	Redo log files that are needed to satisfy the user's requested SCN or time range are missing.
ORA-01292	No log file has been specified for the current LogMiner session.
ORA-01293	Mounted database required for specified LogMiner options.
ORA-01294	Error occurred while processing information in the specified dictionary file, possible corruption.
ORA-01295	Specified LogMiner dictionary does not correspond to the database that produced the log files being analyzed.
ORA-01296	Character set mismatch between specified LogMiner dictionary and log files.
ORA-01297	Redo version mismatch between LogMiner dictionary and log files.
ORA-01299	Specified LogMiner dictionary corresponds to a different database incarnation.
ORA-01300	Writable database required for specified LogMiner options.

Usage Notes

> **Note:**
>
> The continuous_mine option for the dbms_logmnr.start_logmnr package is desupported in Oracle Database 19c (19.1), and is no longer available.

- The DBMS_LOGMNR.ADD_LOGFILE call from a PDB connection is not supported for adhoc users and returns error 65040.
- Users can specify the SCN range or the time range. The required logfiles will be added programmatically.
- Dumping Flat File dictionary and mining using Flat File dictionary are not supported from a PDB connection.
- LogMiner can use a dictionary that you previously extracted to the redo log files or to a flat file, or you can specify that LogMiner use the online catalog if LogMiner is mining data from the source system.
- After executing the START_LOGMNR procedure, you can query the following views:
  - V$LOGMNR_CONTENTS - contains history of information in redo log files

  - V$LOGMNR_DICTIONARY - contains current information about the LogMiner dictionary file extracted to a flat file
  - V$LOGMNR_PARAMETERS - contains information about the LogMiner session

  (You can query the V$LOGMNR_LOGS view after a redo log file list has been added to the list of files that LogMiner is to mine.)

- Parameters and options are not persistent across calls to DBMS_LOGMNR.START_LOGMNR. You must specify all desired parameters and options (including SCN and time ranges) each time you call DBMS_LOGMNR.START_LOGMNR
- Be aware that specifying redo log files using a timestamp is not precise.
- Keep the following in mind regarding starting and ending times or SCN ranges:
  - If you specify neither a startTime nor a startScn parameter, LogMiner will set the startScn parameter to use the lowest SCN value from the redo log file that contains the oldest changes.
  - If you specify both time and SCN values, LogMiner uses the SCN value or values and ignores the time values.
  - If you specify starting and ending time or SCN values and they are found in the LogMiner redo log file list, then LogMiner mines the logs indicated by those values.
  - If you specify starting and ending times or SCN values that are not in the LogMiner redo log file list, and you specify DBMS_LOGMNR.START_LOGMNR, and you specify:
    * 0 for the startTime or startScn value, then the lowest SCN in the LogMiner redo log file list will be used as the startScn
    * A nonzero number for the startTime or startScn value, then an error is returned
    * 0 or a nonzero number for the endTime or endScn value, then the highest SCN in the LogMiner redo log file list will be used as the endScn
  - If you specify starting and ending times or SCN values and they are not found in the LogMiner redo log file list, and you specify DBMS_LOGMNR.START_LOGMNR, and you specify:
    * 0 for the startTime or startScn value, then an error is returned.
    * A startTime or startScn value that is greater than any value in the database's archived redo log files, then LogMiner starts mining in the online redo log file. LogMiner will continue to process the online redo log file until it finds a change at, or beyond, the requested starting point before it returns rows from the V$LOGMNR_CONTENTS view.
    * An endTime or endScn parameter value that indicates a time or SCN in the future, then LogMiner includes the online redo log files when it mines. When you query the V$LOGMNR_CONTENTS view, rows will be returned from this view as changes are made to the database, and will not stop until LogMiner sees a change beyond the requested ending point.
    * 0 for the endTime or endScn parameter value, then LogMiner includes the online redo log files when it mines. When you query the V$LOGMNR_CONTENTS view, rows will be returned from this view as changes are made to the database, and will not stop until you enter CTL+C or you terminate the PL/SQL cursor.

107
DBMS_LOGSTDBY

The DBMS_LOGSTDBY package provides subprograms for configuring and managing the logical standby database environment.

This chapter contains the following topics:

- Overview
- Security Model
- Constants
- Summary of DBMS_LOGSTDBY Subprograms

> **See Also:**
>
> *Oracle Data Guard Concepts and Administration*

107.1 DBMS_LOGSTDBY Overview

The DBMS_LOGSTDBY package helps you manage the SQL Apply (logical standby database) environment.

The subprograms in the DBMS_LOGSTDBY package help you to accomplish the following main objectives:

- Manage configuration parameters used by SQL Apply.

  For example, controlling how transactions are applied on the logical standby database, how much shared pool is used, and how many processes are used by SQL Apply to mine and apply the changes.
- Ensure an appropriate level of supplemental logging is enabled, and a LogMiner dictionary is built correctly for logical standby database creation.
- Provide a way to skip the application of changes to selected tables or entire schemas in the logical standby database, and specify ways to handle exceptions encountered by SQL Apply.
- Allow controlled access to tables in the logical standby database that may require maintenance.

107.2 DBMS_LOGSTDBY Security Model

You must have the DBA role to use the DBMS_LOGSTDBY package.

A prototype role, LOGSTDBY_ADMINISTRATOR, is created by default with RESOURCE and EXECUTE privileges on DBMS_LOGSTDBY. If you choose to use this role, consider granting ALTER

DATABASE and ALTER SESSION privileges to the role so that the grantee can start and stop SQL Apply and can enable and disable the database guard.

The procedures associated with skipping transactions (SKIP and UNSKIP, SKIP_ERROR and UNSKIP_ERROR, and SKIP_TRANSACTION and UNSKIP_TRANSACTION) all require DBA privileges to execute because their scope may contain wildcard schemas. Oracle recommends that where SKIP procedures are specified, these be owned by a secure account with appropriate privileges on the schemas they act on (for example, SYS).

107.3 DBMS_LOGSTDBY Constants

The DBMS_LOGSTDBY package defines several enumerated constants for specifying parameter values. Enumerated constants must be prefixed with the package name, for example, DBMS_LOGSTDBY.SKIP_ACTION_SKIP.

The following table describes the constants for the proc_name parameter in the DBMS_LOGSTDBY.SKIP procedure.

Table 107-1 Constants for SKIP Options Flag

Constant	Description
MAX_EVENTS	Maximum number of events to log in the DBA_LOGSTDBY_EVENTS view. See the DBMS_LOGSTDBY APPLY_SET Procedure.
SKIP_ACTION_APPLY	Used inside the user-defined procedure registered with DBMS_LOGSTDBY.SKIP. Use this constant when setting the value of the SKIP_ACTION parameter with DBMS_LOGSTDBY_CONTEXT if you want SQL Apply to apply the DDL or PL/SQL statement.
SKIP_ACTION_ERROR	Used inside the user-defined procedure registered with DBMS_LOGSTDBY.SKIP. Use this constant when setting the value of the SKIP_ACTION parameter with DBMS_LOGSTDBY_CONTEXT if you want SQL Apply to error out.
SKIP_ACTION_REPLACE	Used inside the user-defined procedure registered with DBMS_LOGSTDBY.SKIP. Use this constant when setting the value of the SKIP_ACTION parameter with DBMS_LOGSTDBY_CONTEXT if you want SQL Apply to apply the replacement DDL. (This constant should not be used while handling an Oracle Supplied PL/SQL procedure call).
SKIP_ACTION_SKIP	Used inside the user-defined procedure registered with DBMS_LOGSTDBY.SKIP. Use this constant when setting the value of the SKIP_ACTION parameter with DBMS_LOGSTDBY_CONTEXT if you want SQL Apply to skip the associated DDL or Oracle supplied PL/SQL procedure call.

107.4 Summary of DBMS_LOGSTDBY Subprograms

This table describes each subprogram of the DBMS_LOGSTDBY procedure, including a reference to the section where each procedure is described in more detail.

In a multitenant container database (CDB), some subprograms must be called from the root. There may be other differences as well. See the individual subprogram descriptions for details.

Table 107-2 DBMS_LOGSTDBY Package Subprograms

Subprogram	Description
APPLY_SET Procedure	Sets the values of various parameters that configure and maintain SQL Apply.
APPLY_UNSET Procedure	Restores the default values of various parameters that configure and maintain SQL Apply.
BUILD Procedure	Ensures supplemental logging is enabled properly and builds the LogMiner dictionary.
INSTANTIATE_TABLE Procedure	Creates and populates a table in the standby database from a corresponding table in the primary database.
IS_APPLY_SERVER Function	This function returns TRUE if it is executed from PL/SQL in the context of a logical standby apply server process. This function is used in conjunction with triggers that have the `fire_once` parameter in the `DBMS_DDL.SET_TRIGGER_FIRING_PROPERTY` subprogram set to FALSE (the default is TRUE). Such triggers are executed when the relevant target is updated by an apply process. This function can be used within the body of the trigger to ensure that the trigger takes different (or no) actions on the primary or on the standby.
MAP_PRIMARY_SCN Function	Maps an SCN relevant to the primary database to a corresponding SCN at the logical standby database. The mapped SCN is conservative in nature, and can thus be used to flash back the logical standby database to compensate for a flashback database operation performed at the primary database.
PREPARE_FOR_NEW_PRIMARY Procedure	Used after a failover, this procedure ensures a local logical standby database that was not involved in the failover has not processed more redo than the new primary database and reports the set of archive redo log files that must be replaced to ensure consistency
PURGE_SESSION Procedure	Identifies the archived redo log files that have been applied to the logical standby database and are no longer needed by SQL Apply
REBUILD Procedure	Records relevant metadata (including the LogMiner dictionary) in the redo stream in case a database that has recently changed its role to a primary database following a failover operation fails to do so during the failover process
SET_TABLESPACE Procedure	Moves metadata tables required by SQL Apply to the user-specified tablespace. By default, the metadata tables are created in the SYSAUX tablespace.
SKIP Procedure	Specifies rules that control database operations that should not be applied to the logical standby database
SKIP_ERROR Procedure	Specifies rules regarding what action to take upon encountering errors.
SKIP_TRANSACTION Procedure	Specifies transactions that should not be applied on the logical standby database. Be careful in using this procedure, because not applying specific transactions may cause data corruption at the logical standby database.

Table 107-2 (Cont.) DBMS_LOGSTDBY Package Subprograms

Subprogram	Description
UNSKIP Procedure	Deletes rules specified by the SKIP procedure.
UNSKIP_ERROR Procedure	Deletes rules specified by the SKIP_ERROR procedure.
UNSKIP_TRANSACTION Procedure	Deletes rules specified by the SKIP_TRANSACTION procedure.

107.4.1 APPLY_SET Procedure

Use this procedure to set values of parameters that configure and manage SQL Apply in a logical standby database environment. All parameters, except for PRESERVE_COMMIT_ORDER, can be changed without having to stop SQL Apply.

In a CDB, the APPLY_SET procedure must be called from the root database.

Syntax

```
DBMS_LOGSTDBY.APPLY_SET (
     inname              IN VARCHAR,
     value               IN VARCHAR);
```

Parameters

Table 107-3 APPLY_SET Procedure Parameters

Parameter	Description
APPLY_SERVERS	Controls the number of APPLIER processes used to apply changes. The maximum number allowed is 1024, provided the MAX_SERVERS parameter is set to accommodate this.
EVENT_LOG_DEST	Controls where SQL Apply records the occurrence of an interesting event. It takes the following values: • DEST_ALL - All events will be recorded in the DBA_LOGSTDBY_EVENTS view and in the alert log. • DEST_EVENTS_TABLE - All events that contain information about user data will be recorded only in the DBA_LOGSTDBY_EVENTS view. This is the default value. For example, if SQL Apply receives an ORA-1403 error, the whole event is recorded in the DBA_LOGSTDBY_EVENTS view. Whereas, the alert log records only that SQL Apply stopped because of ORA-1403. No information regarding the user table or offending statement is logged in the alert log. However, if you stop the SQL Apply engine, it gets recorded in both the DBA_LOGSTDBY_EVENTS view and in the alert log. Note that this parameter affects the behavior of the following parameters: RECORD_APPLIED_DDL, RECORD_SKIP_DDL, RECORD_SKIP_ERRORS, and RECORD_UNSUPPORTED_OPERATIONS. For example, if RECORD_APPLIED_DDL is set to TRUE, but EVENT_LOG_DEST is set to DEST_EVENTS_TABLE, then the applied DDL string will only be recorded in the DBA_LOGSTDBY_EVENTS view.

Table 107-3 (Cont.) APPLY_SET Procedure Parameters

Parameter	Description
LOG_AUTO_DEL_RETENTION_TARGET	This parameter setting is only meaningful if LOG_AUTO_DELETE has been set to TRUE. The value you supply for this parameter controls how long (in minutes) a remote archived log that is received from the primary database will be retained at the logical standby database once all redo records contained in the log have been applied at the logical standby database. The default value is 1440 minutes.
LOG_AUTO_DELETE	Automatically deletes foreign archived redo log files as soon as they have been applied on the logical standby database. By default, a foreign archived redo log file is not deleted until 24 hours (the default value of LOG_AUTO_DEL_RETENTION_TARGET parameter) after it has been applied at the logical standby database. Set to TRUE to enable automatic deletion of archived redo log files. Set to FALSE to disable automatic deletion. The default value is TRUE.
MAX_EVENTS_RECORDED	Number of recent events that will be visible through the DBA_LOGSTDBY_EVENTS view. To record all events encountered by SQL Apply, use the DBMS_LOGSTDBY.MAX_EVENTS constant as the number value. The default value is 10,000.
MAX_SERVERS	Number of processes that SQL Apply uses to read and apply redo. The default value is 9. The maximum number allowed is 2048.
MAX_SGA	Number of megabytes from shared pool in System Global Area (SGA) that SQL Apply will use. The default value is 30 megabytes or one quarter of the value set for SHARED_POOL_SIZE, whichever is lower. The maximum size allowed is 4095 megabytes.
PREPARE_SERVERS	Controls the number of PREPARER processes used to prepare changes. The maximum number allowed is 1024, provided the MAX_SERVERS parameter is set to accommodate this.
PRESERVE_COMMIT_ORDER	TRUE: Transactions are applied to the logical standby database in the exact order in which they were committed on the primary database. This is the default parameter setting. FALSE: Transactions containing non-overlapping sets of rows may be committed in a different order than they were committed on the primary database. Regardless of the level chosen, modifications done to the same row are always applied in the same order as they happened on the primary database. See the Usage Notes for details and recommendations. You cannot modify this parameter while SQL Apply is running.

Table 107-3 (Cont.) APPLY_SET Procedure Parameters

Parameter	Description
RECORD_APPLIED_DDL	Controls whether DDL statements that have been applied to the logical standby database are recorded in the location specified by the EVENT_LOG_DEST parameter. Specify one of the following values: TRUE: Indicates that DDL statements applied to the logical standby database are recorded in the DBA_LOGSTDBY_EVENTS table and the alert log. FALSE: Indicates that applied DDL statements are not recorded. This is the default parameter setting.
RECORD_SKIP_DDL	Controls whether skipped DDL statements are recorded in the location specified by the EVENT_LOG_DEST parameter. Specify one of the following values: TRUE: Skipped DDL statements are recorded in the DBA_LOGSTDBY_EVENTS table and the alert log. This is the default parameter setting. FALSE: Skipped DDL statements are not recorded in the DBA_LOGSTDBY_EVENTS table and the alert log.
RECORD_SKIP_ERRORS	Controls whether skipped errors (as described by the SKIP_ERROR procedure) are recorded in the location specified by the EVENT_LOG_DEST parameter. Specify one of the following values: TRUE: Skipped errors are recorded in the DBA_LOGSTDBY_EVENTS table and the alert log. This is the default parameter setting. FALSE: Skipped errors are not recorded in the DBA_LOGSTDBY_EVENTS table and the alert log.
RECORD_UNSUPPORTED_OPERATIONS	Captures information about transactions running on the primary database that will not be supported by a logical standby database. This procedure records its information as events in the DBA_LOGSTDBY_EVENTS table. Specify one of the following values: TRUE: The information is captured and recorded as events in the DBA_LOGSTDBY_EVENTS table. FALSE: The information is not captured. This is the default.

If a parameter is changed while SQL Apply is running, the change will take effect at some point in the future. In such a case, an informational row is inserted into the DBA_LOGSTDBY_EVENTS view at the time the parameter change takes effect.

Additionally, if you are modifying a parameter while SQL Apply is running on an Oracle RAC configuration, you must be connected to the same instance where SQL Apply is running.

Exceptions

Table 107-4 APPLY_SET Procedure Exceptions

Exception	Description
ORA-16103	Logical Standby apply must be stopped to allow this operation
ORA-16104	invalid Logical Standby option requested
ORA-16236	Logical Standby metadata operation in progress

Usage Notes

- Use the APPLY_UNSET procedure to restore the default settings of a parameter.
- See *Oracle Data Guard Concepts and Administration* for help with tuning SQL Apply and for information about setting appropriate values for different parameters.

Examples

To record DDLs in the DBA_LOGSTDBY_EVENTS view and in the alert log, issue the following statement:

```
SQL> EXECUTE DBMS_LOGSTDBY.APPLY_SET('RECORD_APPLIED_DDL', TRUE);
```

107.4.2 APPLY_UNSET Procedure

Use the APPLY_UNSET procedure to restore the default values of the parameters that you changed with the APPLY_SET procedure.

In a CDB, the APPLY_UNSET procedure must be called from the root database.

Syntax

```
DBMS_LOGSTDBY.APPLY_UNSET (
     inname          IN VARCHAR);
```

Parameters

The parameter information for the APPLY_UNSET procedure is the same as that described for the APPLY_SET procedure. See Table 107-3 for complete parameter information.

Exceptions

Table 107-5 APPLY_UNSET Procedure Exceptions

Exception	Description
ORA-16103	Logical Standby apply must be stopped to allow this operation
ORA-16104	invalid Logical Standby option requested
ORA-16236	Logical Standby metadata operation in progress

Usage Notes

- Use the APPLY_SET procedure to specify a nondefault value for a parameter.

Examples

If you previously specified that applied DDLs show up in the DBA_LOGSTDBY_EVENTS view and the alert log, you can restore the default behavior of SQL Apply regarding applied DDL statements with the following statement:

```
SQL> EXECUTE DBMS_LOGSTDBY.APPLY_UNSET('RECORD_APPLIED_DDL');
```

107.4.3 BUILD Procedure

Use this procedure on the primary database to record relevant metadata (LogMiner dictionary) information in the redo log, which will subsequently be used by SQL Apply. This procedure will enable database-wide primary- and unique-key supplemental logging, if necessary.

In a CDB, the BUILD procedure must be called from the root database on the primary. Additionally, you cannot add or remove PDBs from a CDB while this procedure is executing.

> **Note:**
>
> In databases created using Oracle Database 11*g* release 2 (11.2) or later, supplemental logging information is automatically propagated to any existing physical standby databases. However, for databases in earlier releases, or if the database was created using an earlier release and then upgraded to 11.2, you must check whether supplemental logging is enabled at the physical standby(s) if it is also enabled at the primary database. If it is not enabled at the physical standby(s), then before performing a switchover or failover, you must enable supplemental logging on all existing physical standby databases. To do so, issue the following SQL command on each physical standby:
>
> ```
> SQL>  ALTER DATABASE ADD SUPPLEMENTAL LOG DATA (PRIMARY KEY, UNIQUE
> INDEX) COLUMNS;
> ```
>
> If you do not do this, then any logical standby that is also in the same Data Guard configuration will be unusable if a switchover or failover is performed to one of the physical standby databases. If a switchover or failover has already occurred and supplemental logging was not enabled, then you must recreate all logical standby databases.

Syntax

```
DBMS_LOGSTDBY.BUILD;
```

Usage Notes

- Supplemental log information includes extra information in the redo logs that uniquely identifies a modified row in the logical standby database, and also includes information that helps efficient application of changes to the logical standby database.
- LogMiner dictionary information allows SQL Apply to interpret data in the redo logs.

- DBMS_LOGSTDBY.BUILD should be run only once for each logical standby database you want to create. You do not need to use DBMS_LOGSTDBY.BUILD for each Oracle RAC instance.
- DBMS_LOGSTDBY.BUILD waits for all transactions (including distributed transactions) that are active at the time of the procedure invocation to complete before returning. See *Oracle Database Administrator's Guide* for information about how to handle in-doubt transactions.

Examples

To build the LogMiner dictionary in the redo stream of the primary database and to record additional information so that a logical standby database can be instantiated, issue the following SQL statement at the primary database

```
SQL> EXECUTE DBMS_LOGSTDBY.BUILD;
```

107.4.4 INSTANTIATE_TABLE Procedure

This procedure creates and populates a table in the standby database from a corresponding table in the primary database.

The table requires the name of the database link (dblink) as an input parameter. If the table already exists in the logical standby database, it will be dropped and re-created based on the table definition at the primary database. This procedure only brings over the data associated with the table, and not the associated indexes and constraints.

Use the INSTANTIATE_TABLE procedure to:

- Add a table to a standby database.
- Re-create a table in a standby database.

In a CDB, the INSTANTIATE_TABLE procedure must be called from within the container in which the table to be instantiated resides. Additionally, the database link that is provided to the primary database must point to the corresponding container on the primary.

Syntax

```
DBMS_LOGSTDBY.INSTANTIATE_TABLE (
     schema_name         IN VARCHAR2,
     table_name          IN VARCHAR2,
     dblink              IN VARCHAR2);
```

Parameters

Table 107-6 INSTANTIATE_TABLE Procedure Parameters

Parameter	Description
schema_name	Name of the schema
table_name	Name of the table to be created or re-created in the standby database
dblink	Name of the database link account that has privileges to read and lock the table in the primary database, as well as the SELECT_CATALOG_ROLE on the primary database

Exceptions

Table 107-7 INSTANTIATE_TABLE Procedure Exceptions

Exception	Description
ORA-16103	Logical Standby apply must be stopped to allow this operation
ORA-16236	Logical Standby metadata operation in progress
ORA-16276	Specified database link does not correspond to primary database
ORA-16277	Specified table is not supported by logical standby database
ORA-16278	Specified table has a multi-object skip rule defined

Usage Notes

- Use this procedure to create and populate a table in a way that keeps the data on the standby database transactionally consistent with the primary database.
- This table will not be synchronized with the rest of the tables being maintained by SQL Apply and SQL Apply will not start to maintain it until SQL Apply encounters redo that occurred after the table was instantiated from the primary. The SCN at which the table was instantiated from the primary database is available in the DBA_LOGSTDBY_EVENTS view.
- The specified table must be a table that is supported by logical standby (that is, it does not appear in the DBA_LOGSTDBY_UNSUPPORTED_TABLES view on the primary database).
- If there are any skip rules that specifically name this table (without any wildcards), those skip rules will be dropped as part of INSTANTIATE_TABLE, so that the table will be properly maintained by SQL Apply in the future. If there are skip rules that indirectly reference this table (match a skip rule with a wildcard in the schema_name or table_name, and have a TABLE, DML, or SCHEMA_DDL statement type), INSTANTIATE_TABLE will fail with an ORA-16278 error. Any multi-object skip rules that pertain to the table must be dropped or changed before re-attempting the INSTANTIATE_TABLE call.

Examples

```
SQL> EXECUTE DBMS_LOGSTDBY.INSTANTIATE_TABLE (-
     SCHEMA_NAME => 'HR', TABLE_NAME => 'EMPLOYEES', -
     DBLINK => 'INSTANTIATE_TBL_LINK');
```

107.4.5 IS_APPLY_SERVER Function

This function returns TRUE if it is executed from PL/SQL in the context of a logical standby apply server process.

This function is used in conjunction with triggers that have the fire_once parameter in the DBMS_DDL.SET_TRIGGER_FIRING_PROPERTY subprogram set to FALSE (the default is TRUE). Such triggers are executed when the relevant target is updated by an apply process. This function can be used within the body of the trigger to ensure that the trigger takes different (or no) actions on the primary or on the standby.

Syntax

```
DBMS_LOGSTDBY.IS_APPLY_SERVER
RETURN BOOLEAN;
```

Parameters

None

107.4.6 MAP_PRIMARY_SCN Function

This function returns an SCN on the standby that predates the supplied SCN from the primary database by at least 5 minutes.

It can be used to determine a safe SCN to use in a compensating flashback database operation at the logical standby database, following a flashback database operation or a point-in-time recovery operation at the primary database.

Syntax

```
DBMS_LOGSTDBY.MAP_PRIMARY_SCN(primary_scn NUMBER) RETURN NUMBER;
```

Exceptions

Table 107-8 MAP_PRIMARY_SCN Function Exceptions

Exception	Description
ORA-20001	Primary SCN is before mapped range
ORA-20002	SCN mapping requires PRESERVE_COMMIT_ORDER to be TRUE

Usage Notes

Use this function to get a conservative SCN at the logical standby database that corresponds to an SCN at the primary database. This function is useful in the context of doing compensating flashback database operations at the logical standby following a flashback database or a point-in-time recovery operation done at the primary database.

107.4.7 PREPARE_FOR_NEW_PRIMARY Procedure

The PREPARE_FOR_NEW_PRIMARY procedure must be invoked at a logical standby database following a failover, if that standby database was not the target of the failover operation.

Such a standby database must process the exact same set of redo logs processed at the new primary database. This routine ensures that the local logical standby database has not processed more redo than the new primary database and reports the set of archive logs that must be replaced to ensure consistency. The set of replacement logs will be reported in the alert.log. These logs must be copied to the logical standby and registered using the ALTER DATABASE REGISTER LOGICAL LOGFILE statement.

In a CDB, the PREPARE_FOR_NEW_PRIMARY procedure must be called from the root database.

Syntax

```
DBMS_LOGSTDBY.PREPARE_FOR_NEW_PRIMARY (
           FORMER_STANDBY_TYPE         IN VARCHAR2,
           DBLINK                      IN VARCHAR2);
```

Parameters

Table 107-9 PREPARE_FOR_NEW_PRIMARY Procedure Parameters

Parameter	Description
FORMER_STANDBY_TYPE	The type of standby database that was the target of the failover operation to become the new primary database. Valid values are 'PHYSICAL' if the new primary was formerly a physical standby, and 'LOGICAL' if the new primary database was formerly a logical standby database.
DBLINK	The name of a database link to the new primary database

Exceptions

Table 107-10 PREPARE_FOR_NEW_PRIMARY Procedure Exceptions

Exception	Description
ORA-16104	Invalid Logical Standby option.
ORA-16109	Failed to apply log data from previous primary.

Usage Notes

- This routine is intended only for logical standby systems.This routine will fail if the new primary database was formerly a logical standby database and the LogMiner dictionary build has not completed successfully.Log files displayed in the alert log will be referred to as *terminal logs*. Users should keep in mind that file paths are relative to the new primary database and may not resolve locally.Upon manual registration of the terminal logs, users should complete the process by calling either `START LOGICAL STANDBY APPLY` if the new primary database was formerly a physical standby database or `START LOGICAL STANDBY APPLY NEW PRIMARY` if the new primary database was formerly a logical standby database.See the alert log for more details regarding the reasons for any exception.

Examples

```
SQL> EXECUTE DBMS_LOGSTDBY.PREPARE_FOR_NEW_PRIMARY (  -
                FORMER_STANDBY_TYPE => 'LOGICAL',    -
                DBLINK => 'dblink_to_newprimary');
```

107.4.8 PURGE_SESSION Procedure

`PURGE_SESSION` identifies all archived redo log files that have been applied to the logical standby database and are no longer needed by SQL Apply.

Once identified, you can issue operating system commands to delete some or all of the unnecessary archived redo log files.

In a CDB, the PURGE_SESSION procedure must be called from the root database.

Syntax

```
DBMS_LOGSTDBY.PURGE_SESSION;
```

Exceptions

Table 107-11 PURGE_SESSION Procedure Exceptions

Exception	Description
ORA-01309	Invalid session

Usage Notes

- This procedure does not delete the archived redo log files. You must issue operating system commands to delete unneeded files.
- This procedure updates the DBA_LOGMNR_PURGED_LOG view that displays the archived redo log files that have been applied to the logical standby database.
- In Oracle Database 10*g* Release 2, metadata related to the archived redo log files (and the actual archived redo log files) are purged automatically based on the default setting of the LOG_AUTO_DELETE parameter described in the DBMS_LOGSTDBY.APPLY_SET procedure described.

Example

To identify and remove unnecessary files:

1. Enter the following statement on the logical standby database:

   ```
   SQL> EXECUTE DBMS_LOGSTDBY.PURGE_SESSION;
   ```

2. Query the DBA_LOGMNR_PURGED_LOG view to list the archived redo log files that can be removed:

   ```
   SQL> SELECT * FROM DBA_LOGMNR_PURGED_LOG;

   FILE_NAME
      -----------------------------------
      /boston/arc_dest/arc_1_40_509538672.log
      /boston/arc_dest/arc_1_41_509538672.log
      /boston/arc_dest/arc_1_42_509538672.log
      /boston/arc_dest/arc_1_43_509538672.log
      /boston/arc_dest/arc_1_44_509538672.log
      /boston/arc_dest/arc_1_45_509538672.log
      /boston/arc_dest/arc_1_46_509538672.log
      /boston/arc_dest/arc_1_47_509538672.log
   ```

3. Use operating system-specific commands to delete archived redo log files from the file system.

107.4.9 REBUILD Procedure

This procedure is used if a database that has recently changed its role to a primary database following a failover operation fails to record relevant metadata (including the LogMiner dictionary) in the redo stream required for other logical standby databases.

In a CDB, the `REBUILD` procedure must be called from the root database.

Syntax

```
DBMS_LOGSTDBY.REBUILD;
```

Usage Notes

- LogMiner dictionary information is logged in the redo log files.The standby redo log files (if present) are archived.

Examples

```
SQL> EXECUTE DBMS_LOGSTDBY.REBUILD;
```

107.4.10 SET_TABLESPACE Procedure

This procedure moves metadata tables required by SQL Apply to the user-specified tablespace.

By default, the metadata tables are created in the `SYSAUX` tablespace. SQL Apply cannot be running when you invoke this procedure.

In a CDB, the `SET_TABLESPACE` procedure must be called from the root database.

Syntax

```
DBMS_LOGSTDBY.SET_TABLESPACE(
           NEW_TABLESPACE IN VARCHAR2)
```

Parameters

Table 107-12 SET_TABLE SPACE Procedure Parameters

Parameter	Description
`NEW_TABLESPACE`	Name of the new tablespace where metadata tables will reside.

Exceptions

Table 107-13 SET_TABLESPACE Procedure Exceptions

Exception	Description
`ORA-16103`	Logical Standby apply must be stopped to allow this operation
`ORA-16236`	Logical Standby metadata operation in progress

Examples

To move metadata tables to a new tablespace named LOGSTDBY_TBS, issue the following statement:

```
SQL> EXECUTE DBMS_LOGSTDBY.SET_TABLESPACE (new_tablespace => 'LOGSTDBY_TBS');
```

107.4.11 SKIP Procedure

The SKIP procedure can be used to define rules that will be used by SQL Apply to skip the application of certain changes to the logical standby database.

For example, the SKIP procedure can be used to skip changes to a subset of tables in the logical standby database. It can also be used to specify DDL statements that should not be applied at the logical standby database or should be modified before they are applied in the logical standby database. One reason why a DDL statement may need to be modified is to accommodate a different directory structure on the logical standby database.

> **Note:**
>
> For information about skipping containers, see "Skipping Containers."

Syntax

```
DBMS_LOGSTDBY.SKIP (
     stmt                      IN VARCHAR2,
     schema_name               IN VARCHAR2 DEFAULT NULL,
     object_name               IN VARCHAR2 DEFAULT NULL,
     proc_name                 IN VARCHAR2 DEFAULT NULL,
     use_like                  IN BOOLEAN DEFAULT TRUE,
     esc                       IN CHAR1 DEFAULT NULL);
```

Parameters

Table 107-14 SKIP Procedure Parameters

Parameter	Description
stmt	Either a keyword that identifies a set of SQL statements or a specific SQL statement. The use of keywords simplifies configuration since keywords, generally defined by the database object, identify all SQL statements that operate on the specified object. Table 107-15 shows a list of keywords and the equivalent SQL statements, either of which is a valid value for this parameter. The keyword PL/SQL is used for the execution of Oracle-supplied packages which are supported for replication.
schema_name	The name of one or more schemas (wildcards are permitted) associated with the SQL statements identified by the stmt parameter. If not applicable, this value must be set to NULL.
object_name	The name of one or more objects (wildcards are permitted) associated with the SQL statements identified by the stmt. If not applicable, this value must be set to NULL.

Table 107-14 (Cont.) SKIP Procedure Parameters

Parameter	Description
proc_name	Name of a stored procedure to call when SQL Apply determines that a particular statement matches the filter defined by the stmt, schema_name, and object_name parameters. Specify the procedure in the following format: 'schema.package.procedure' This procedure returns a value that directs SQL Apply to perform one of the following: execute the statement, skip the statement, or execute a replacement statement. The procedures to be invoked in the case of DDL or PL/SQL take no arguments. You can access the various information needed inside the procedure by accessing the context associated with the namespace,LSBY_APPLY_CONTEXT. For a full list of parameters that are accessible in the context of the skip procedure, see the DBMS_LOGSTBDY_CONTEXT package. The parameters of interest in the case of DDLs are: STATEMENT, STATEMENT_TYPE, SCHEMA, NAME, CURENT_SCHEMA, XIDUSN, XIDSLT, XIDSQN and SKIP_ACTION. The parameters of interest in the case of PL/SQL are: STATEMENT, PACKAGE_SCHMEMA, PACKAGE_NAME, PROCEDURE_NAME, CURRENT_SCHEMA, XIDUSN, XIDSLT, XIDSQN, EXIT_STATUS, and SKIP_ACTION.. **Note 1**: The DBMS_LOGSTDBY.SKIP_ACTION_REPLACE constant is not supported for PL/SQL. **Note 2**: SQL Apply calls the skip handler when the procedure's exit is processed. **Note 3**: The use_like parameter must be set to FALSE for PL/SQL since wildcarding PL/SQL is not supported.

Table 107-14 (Cont.) SKIP Procedure Parameters

Parameter	Description

proc_name (cont.)	A sample conditional skip rule on DBMS_RLS.DROP_POLICY is as follows:
	`create or replace procedure sec.mgr.skip_drop_policy`
	`is`
	`l_stmt  CLOB;`
	`l_pkgown varchar2(30);`
	`l_pkgnam varchar2(30);`
	`l_procnm varchar2(30);`
	`l_cur_schema varchar2(30);`
	`l_xidusn   number;`
	`l_xidslt   number;`
	`l_xidsqn   number;`
	`l_exit_status number;`
	`l_skip_action number;`
	`Begin`
	`-- read all relevant info`
	`dbms_logstdby_context.get_context(name => 'STATEMENT', value => l_stmt);`
	`dbms_logstdby_context.get_context(name => 'PACKAGE_SCHEMA', value =>`
	`l_pkgown);`
	`dbms_logstdby_context.get_context(name => 'PACKAGE_NAME', value =>`
	`l_pkgnam);`
	`dbms_logstdby_context.get_context(name => 'PROCEDURE_NAME', value =>`
	`l_procnm);`
	`dbms_logstdby_context.get_context(name => 'CURRENT_SCHEMA', value =>`
	`l_cur_schema);`
	`dbms_logstdby_context.get_context(name => 'XIDUSN', value => l_xidusn);`
	`dbms_logstdby_context.get_context(name => 'XIDSLT', value => l_xidslt);`
	`dbms_logstdby_context.get_context(name => 'XIDSQN', value => l_xidsqn);`
	`dbms_logstdby_context.get_context(name => 'EXIT_STATUS', value =>`
	`l_ext_status);`
	
	`if 0 == l_ext_status then`
	`Insert Into sec_mgr.logit Values`
	`      ('Success: '||l_pkgown||'.'||l_pkgnm||'.'||l_procnm|| ' by '||`
	`l_current_user);`
	
	`If l_current_user != 'TESTSCHEMA' Then`
	`      l_skip_action := DBMS_LOGSTDBY.SKIP_ACTION_APPLY;`
	`    Else`
	`      l_skip_action := DBMS_LOGSTDBY.SKIP_ACTION_SKIP;`
	`    End If;`
	`  End If;`
	
	`dbms_logstdby_context.set_context(name=>'SKIP_ACTION',`
	`value => l_skip_action);`
	
	`End skip_drop_policy;`
	
	`EXECUTE DBMS_LOGSTDBY.SKIP( -`
	`     stmt => 'PL/SQL', -`
	`     schema_name => 'SYS', -`
	`     object_name => 'DBMS_RLS.DROP_POLICY', -`
	`     proc_name => 'SEC_MGR.SKIP_DROP_POLICY' -`
	`     use_like=> FALSE);`

Table 107-14 (Cont.) SKIP Procedure Parameters

Parameter	Description
use_like	Allows pattern matching to isolate the tables that you want to skip on the logical standby database. The use_like parameter matches a portion of one character value to another by searching the first value for the pattern specified by the second, and calculates strings using characters as defined by the input character set. This parameter follows the same rules for pattern matching described in *Oracle Database SQL Language Reference*.
esc	Identifies an escape character (such as the character "/") that you can use for pattern matching. If the escape character appears in the pattern before the character "%" or "_" then Oracle interprets this character literally in the pattern, rather than as a special pattern matching character. See *Oracle Database SQL Language Reference* for more information about pattern matching.

Usage Notes

- This procedure requires DBA privileges to execute.
- You cannot associate a stored procedure to be invoked in the context of a DML statement. For example, the following statement returns the ORA-16104: invalid Logical Standby option requested error:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP(-
     stmt => 'DML', -
     schema_name => 'HR', -
     object_name => 'EMPLOYEES', -
     proc_name => 'DML_HANDLER');
```

  Also, if an event matches multiple rules either because of the use of wildcards while specifying the rule or because of a specification of overlapping rules. For example, if you specify a rule for the SCHEMA_DDL event for the HR.EMPLOYEES table, and a rule for the ALTER TABLE event for the HR.EMPLOYEES table, only one of the matching procedures will be invoked (alphabetically, by procedure). In the following code example, consider the following rules:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP( -
     stmt => 'SCHEMA_DDL', -
     schema_name => 'HR', -
     object_name => 'EMPLOYEES', -
     proc_name => 'SCHEMA_DDL_HANDLER');
SQL> EXECUTE DBMS_LOGSTDBY.SKIP( -
     stmt => 'ALTER TABLE', -
     schema_name => 'HR', -
     object_name => 'EMPLOYEES', -
     proc_name => 'TABLE_ALTER_HANDLER');
```

  On encountering an ALTER TABLE statement, the schema_ddl_handler procedure will be invoked because its name will be at the top of an alphabetically sorted list of procedures that are relevant to the statement.Collisions on a rule set because of a specification containing wildcard entries are resolved in a similar fashion. For example, the rules in the following example will result in the empddl_handler procedure being invoked upon encountering the ALTER TABLE HR.EMPLOYEES ADD COLUMN RATING NUMBER statement:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP(-
     stmt => 'ALTER TABLE', -
```

```
     schema_name => 'HR', -
     object_name => 'EMP%', -
     proc_name => 'EMPDDL_HANDLER');
SQL> EXECUTE DBMS_LOGSTDBY.SKIP( -
     stmt => 'ALTER TABLE', -
     schema_name => 'HR', -
     object_name => 'EMPLOYEES', -
     proc_name => 'EMPLOYEE_DDL_HANDLER');
```

- Use the SKIP procedure with caution, particularly when skipping DDL statements. If a CREATE TABLE statement is skipped, for example, you must also specify other DDL statements that refer to that table in the SKIP procedure. Otherwise, the statements will fail and cause an exception. When this happens, SQL Apply stops running.
- Before calling the SKIP procedure, SQL Apply must be halted. Do this by issuing an ALTER DATABASE STOP LOGICAL STANDBY APPLY statement. Once all desired filters have been specified, issue an ALTER DATABASE START LOGICAL STANDBY APPLY IMMEDIATE statement to start SQL Apply using the new filter settings.
- See the UNSKIP procedure for information about reversing (undoing) the settings of the SKIP procedure.
- For USER statements, the SCHEMA_NAME parameter will be the user and specify '%' for the OBJECT_NAME parameter.
- If the PROC_NAME parameter is supplied, it must already exist in DBA_PROCEDURES and it must execute with DEFINER rights. If the procedure is declared with INVOKER rights, the ORA-1031: insufficient privileges message will be returned.
- If the procedure returns a REPLACEMENT statement, the REPLACEMENT statement will be executed using the SYSTEM and OBJECT privileges of the owner of the procedure.
- The PL/SQL block of a SKIP procedure cannot contain transaction control statements (for example, COMMIT, ROLLBACK, SAVEPOINT, and SET CONSTRAINT) unless the block is declared to be an autonomous transaction.

Skip Statement Options

Table 107-15 lists the supported values for the stmt parameter of the SKIP procedure. The left column of the table lists the keywords that may be used to identify the set of SQL statements to the right of the keyword. In addition, any of the SQL statements listed in the sys.audit_actions table (shown in the right column of Table 107-15) are also valid values. Note that keywords are generally defined by database object.

Table 107-15 Supported Values for the stmt Parameter

Keyword	Associated SQL Statements
There is no keyword for this group of SQL statements.	GRANT REVOKE ANALYZE TABLE ANALYZE INDEX ANALYZE CLUSTER
CLUSTER	AUDIT CLUSTER CREATE CLUSTER DROP CLUSTER TRUNCATE CLUSTER

Table 107-15 (Cont.) Supported Values for the `stmt` Parameter

Keyword	Associated SQL Statements
CONTAINER	See "Skipping Containers"
CONTEXT	CREATE CONTEXT DROP CONTEXT
DATABASE LINK	CREATE DATABASE LINK CREATE PUBLIC DATABASE LINK DROP DATABASE LINK DROP PUBLIC DATABASE LINK
DIMENSION	ALTER DIMENSION CREATE DIMENSION DROP DIMENSION
DIRECTORY[1]	CREATE DIRECTORY DROP DIRECTORY
DML	Includes DML statements on a table (for example: INSERT, UPDATE, and DELETE)
INDEX	ALTER INDEX CREATE INDEX DROP INDEX
NON_SCHEMA_DDL	*All DDL that does not pertain to a particular schema* **Note:** SCHEMA_NAME and OBJECT_NAME must be null
PL/SQL[2]	Execute Oracle-supplied package.
PROCEDURE[3]	ALTER FUNCTION ALTER PACKAGE ALTER PACKAGE BODY ALTER PROCEDURE CREATE FUNCTION CREATE LIBRARY CREATE PACKAGE CREATE PACKAGE BODY CREATE PROCEDURE DROP FUNCTION DROP LIBRARY DROP PACKAGE DROP PACKAGE BODY DROP PROCEDURE
PROFILE	ALTER PROFILE CREATE PROFILE DROP PROFILE

Table 107-15 (Cont.) Supported Values for the `stmt` Parameter

Keyword	Associated SQL Statements
ROLE	ALTER ROLE CREATE ROLE DROP ROLE SET ROLE
ROLLBACK STATEMENT	ALTER ROLLBACK SEGMENT CREATE ROLLBACK SEGMENT DROP ROLLBACK SEGMENT
SCHEMA_DDL	*All DDL statements that create, modify, or drop schema objects (for example: tables, indexes, and columns)* **Note:** SCHEMA_NAME and OBJECT_NAME must *not* be null
SEQUENCE	ALTER SEQUENCE CREATE SEQUENCE DROP SEQUENCE
SYNONYM	CREATE PUBLIC SYNONYM CREATE SYNONYM DROP PUBLIC SYNONYM DROP SYNONYM
SYSTEM AUDIT	AUDIT *SQL_statements* NOAUDIT *SQL_statements*
TABLE	CREATE TABLE ALTER TABLE DROP TABLE TRUNCATE TABLE
TABLESPACE	CREATE TABLESPACE DROP TABLESPACE ALTER TABLESPACE
TRIGGER	ALTER TRIGGER CREATE TRIGGER DISABLE ALL TRIGGERS DISABLE TRIGGER DROP TRIGGER ENABLE ALL TRIGGERS ENABLE TRIGGER

Table 107-15 (Cont.) Supported Values for the `stmt` Parameter

Keyword	Associated SQL Statements
TYPE	ALTER TYPE ALTER TYPE BODY CREATE TYPE CREATE TYPE BODY DROP TYPE DROP TYPE BODY
USER	ALTER USER CREATE USER DROP USER
VIEW	CREATE VIEW DROP VIEW
VIEW	CREATE VIEW DROP VIEW

[1] All directory objects are owned by SYS, but for the purpose of filtering them with a skip directive the schema should be specified as '%"'.
[2] See *Oracle Data Guard Concepts and Administration* for information about supported packages.
[3] Java schema objects (sources, classes, and resources) are considered the same as procedure for purposes of skipping (ignoring) SQL statements.

Exceptions

Table 107-16 DBMS_LOGSTDBY.SKIP Procedure Exceptions

Exception	Description
ORA-01031	Insufficient privileges: • Procedure used INVOKER rights • Procedure needs DBA privileges
ORA-16103	Logical standby apply must be stopped to allow this operation.
ORA-16104	Invalid logical standby option requested.
ORA-16203	"Unable to interpret SKIP procedure return values." Indicates that a SKIP procedure has either generated an exception or has returned ambiguous values. You can identify the offending procedure by examining the DBA_LOGSTDBY_EVENTS view.
ORA-16236	Logical standby metadata operation in progress.

Examples

Example 1. Skipping all DML and DDL changes made to a schema
The following example shows how to specify rules so that SQL Apply will skip both DDL and DML statements made to the HR schema.

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP(STMT => 'SCHEMA_DDL', -
     schema_name => 'HR', -
     object_name => '%', -
     proc_name => null);
SQL> EXECUTE DBMS_LOGSTDBY.SKIP(STMT => 'DML', -
     schema_name => 'HR', -
     object_name => '%', -
     proc_name => null);
```

Example 2. Creating a procedure to handle different file system organization
For example, if the file system organization in the logical standby database is different than that in the primary database, you can write a `SKIP` procedure to handle DDL statements with file specifications transparently.The following procedure can handle DDL statements as long as you follow a specific naming convention for the file specification string.

1. Create the `SKIP` procedure to handle tablespace DDL statements:

```
CREATE OR REPLACE PROCEDURE sys.handle_tbs_ddl
IS
l_old_stmt varchar2(4000);
l_stmt_typ varcahr2(40);
l_schema   varchar2(30);
l_name     varchar2(30);
l_xidusn   number;
l_xidslt   number;
l_xidsqn   number;
l_skip_action number;
l_new_stmt varchar2(4000);

-- read all information
dbms_logstdby_context.get_context(name=>'STATEMENT',value=>l_old_stmt);
  dbms_logstdby_context.get_context(name=>'STATEMENT_TYPE',value=>l_stmt_type);
  dbms_logstdby_context.get_context(name=>'OWNER',value=>l_schema);
  dbms_logstdby_context.get_context(name=>'NAME',value=>l_name);
  dbms_logstdby_context.get_context(name=>'XIDUSN',value=>l_xidusn);
  dbms_logstdby_context.get_context(name=>'XIDSLT',value=>l_xidslt);
  dbms_logstdby_context.get_context(name=>'XIDSQN',value=>l_xidsqn);
  dbms_logstdby_context.get_context(name=>'CONTAINER_NAME',value=>l_conname);

--
-- All primary file specification that contains a directory
-- /usr/orcl/primary/dbs
-- should go to /usr/orcl/stdby directory specification

  BEGIN
  l_new_stmt := replace (l_old_stmt, '/usr/orcl/primary/dbs','/usr/orcl/stdby');
l_skip_action := DBMS_LOGSTDBY.SKIP_ACTION_REPLACE;
  EXCEPTION
  WHEN OTHERS THEN
    l_skip_action := DBMS_LOGSTDBY.SKIP_ACTION_ERROR;
    l_new_stmt := NULL;
```

```
  END;

  dbms_logstdby_context.set_context(name=>new_statement, value =>
l_new_stmt);
dbms_logstdby_context.set_context(name=>'SKIP_ACTION', value =>
l_skip_action);
END handle_tbs_ddl;
```

2. Register the SKIP procedure with SQL Apply:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP (stmt => 'TABLESPACE', -
             proc_name => 'SYS.HANDLE_TBS_DDL');
```

Skipping Containers

To skip a container (either a PDB or the root), use the CONTAINER keyword. All SQL statements executed on the container, as well as any other actions taken on the container, are skipped.

You can skip a particular PDB within a CDB. For example, the following command skips the PDB named PDB1. The command must be executed at the root level:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP(stmt => 'CONTAINER', object_name => 'PDB1');
```

As shown in the following example, you could also skip only the root of the CDB, but not any of the PDBs that exist under the root. The command must be executed at the root level:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP(stmt => 'CONTAINER', object_name => 'CDB$ROOT');
```

> **Note:**
>
> To create other skip rules for a container, create the rules from within the container. The container to which the rules will apply is automatically derived from the container in which the rules are created.

107.4.12 SKIP_ERROR Procedure

The SKIP_ERROR procedure specifies the action to take when a logical standby database detects an error.

Upon encountering an error, the logical standby database uses the criteria contained in this procedure to determine a course of action. The default action when a match is found is to skip the error and continue with applying changes. However, if a procedure is supplied, then SKIP_ERROR can take other actions depending on the situation. It can do nothing, which causes SQL Apply to stop, or it can change the error message text and stop SQL Apply, or it can actually skip the error.

Syntax

```
DBMS_LOGSTDBY.SKIP_ERROR (
     stmt                      IN VARCHAR2,
     schema_name               IN VARCHAR2 DEFAULT NULL,
     object_name               IN VARCHAR2 DEFAULT NULL,
     proc_name                 IN VARCHAR2 DEFAULT NULL,
     use_like                  IN BOOLEAN  DEFAULT NULL,
     esc                       IN CHAR1    DEFAULT NULL);
```

Parameters

Table 107-17 SKIP_ERROR Procedure Parameters

Parameter	Description
stmt	Either a keyword that identifies a set of SQL statements or a specific SQL statement. The use of keywords simplifies configuration because keywords, generally defined by the database object, identify all SQL statements that operate on the specified object. Table 107-15 shows a list of keywords and the equivalent SQL statements, either of which is a valid value for this parameter.
schema_name	The name of one or more schemas (wildcards are permitted) associated with the SQL statements identified by the stmt parameter. If not applicable, this value must be set to NULL.
object_name	The name of one or more objects (wildcards are permitted) associated with the SQL statements identified by the stmt. If not applicable, this value must be set to NULL.
proc_name	Name of a stored procedure to call when SQL Apply encounters an error and determines a particular statement matches the filter defined by the stmt, schema_name, and object_name parameters. Specify the procedure in the following format: '"schema"."package"."procedure"' This procedure returns an error message that directs SQL Apply to perform one of the following actions: • Silently skip the error and continue with SQL Apply • Replace the error message that would have been created with a custom one, and stop SQL Apply • Do nothing, causing SQL Apply to stop and the original error message to be logged The procedure registered with SQL Apply does not take any parameters. The context associated with LSBY_APPLY_CONTEXT can be used to retrieve all relevant information related to the error. See the DBMS_LOGSTDBY_CONTEXT package for a list of all parameters associated with LSBY_APPLY_CONTEXT. The parameters of interest for procedures registered with SKIP_ERROR are CONTAINER_NAME, STATEMENT, STATEMENT_TYPE, SCHEMA, NAME, XIDUSN, XIDSLT, XIDSQN, ERROR and NEW_ERROR.
use_like	Allows pattern matching to isolate the tables that you want to skip on the logical standby database. The use_like parameter matches a portion of one character value to another by searching the first value for the pattern specified by the second, and calculates strings using characters as defined by the input character set. This parameter follows the same rules for pattern matching described in *Oracle Database SQL Language Reference*.
esc	Identifies an escape character (such as the characters "%" or "_") that you can use for pattern matching. If the escape character appears in the pattern before the character "%" or "_" then Oracle interprets this character literally in the pattern, rather than as a special pattern matching character.

Usage Notes

- A stored procedure provided to the SKIP_ERROR procedure is called when SQL Apply encounters an error that could shut down the application of redo logs to the standby database.
- Running this stored procedure affects the error being written in the STATUS column of the DBA_LOGSTDBY_EVENTS table. The STATUS_CODE column remains unchanged. If the stored procedure is to have no effect, that is, apply will be stopped, then the NEW_ERROR is written to the events table. To truly have no effect, set NEW_ERROR to ERROR in the procedure.
- If the stored procedure requires that a shutdown be avoided, then you must set NEW_ERROR to NULL.
- This procedure requires DBA privileges to execute.
- For USER statements, the SCHEMA_NAME parameter will be the user and you should specify '%' for the OBJECT_NAME parameter.
- If the PROC_NAME parameter is specified, it must already exist in DBA_PROCEDURES and it must execute with DEFINERS rights. If the procedure is declared with INVOKERS rights, the ORA-1031: insufficient privileges message will be returned.
- The PL/SQL block of a SKIP_ERROR procedure cannot contain transaction control statements (for example: COMMIT, ROLLBACK, SAVEPOINT, and SET CONSTRAINT) unless the block is declared to be an autonomous transaction using the following syntax:

  ```
  PRAGMA AUTONOMOUS_TRANSACTION
  ```

Exceptions

Table 107-18 SKIP_ERROR Procedure Exceptions

Exception	Description
ORA-01031	Insufficient privileges: • Procedure used INVOKER rights • Procedure needs DBA privileges
ORA-16103	Logical Standby apply must be stopped to allow this operation
ORA-16104	invalid Logical Standby option requested
ORA-16236	Logical Standby metadata operation in progress

Example 1

The following example shows how to specify rules so that SQL Apply will skip any error raised from any GRANT DDL command.

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP_ERROR('GRANT')
```

Example 2

To skip errors on GRANT statements on SYS or HR schemas, define a procedure handle_error_ddl and register it. In the following example, assume that handle_error_ddl is a free-standing procedure in the SYS schema.

1. Create the error-handler procedure:

```
CREATE OR REPLACE PROCEDURE sys.handle_error_ddl
is
l_stmt    VARCHAR2(4000);
l_stmt_type VARCHAR2(40);
l_schema    VARCHAR2(30);
l_name      VARCHAR2(30);
l_xidusn      NUMBER;
l_xidslt      NUMBER;
l_xidsqn      NUMBER;
l_error     VARCHAR2(4000);
l_conname    VARCHAR2(30);
l_newerr   VARCHAR2(4000);

BEGIN
 dbms_logstdby_context.get_context(name=>'STATEMENT',value=>l_stmt);
  dbms_logstdby_context.get_context(name=>'STATEMENT_TYPE',value=>l_stmt_type);
  dbms_logstdby_context.get_context(name=>'SCHEMA',value=>l_schema);
  dbms_logstdby_context.get_context(name=>'NAME',value=>l_name);
  dbms_logstdby_context.get_context(name=>'XIDUSN',value=>l_xidusn);
  dbms_logstdby_context.get_context(name=>'XIDSLT',value=>l_xidslt);
  dbms_logstdby_context.get_context(name=>'XIDSQN',value=>l_xidsqn);
  dbms_logstdby_context.get_context(name=>'ERROR',value=>l_error);
  dbms_logstdby_context.get_context(name=>'CONTAINER_NAME',value=>l_conname);

-- default error to what we already have
l_new_error := l_error;

-- Ignore any GRANT errors on SYS or HR schemas

IF INSTR(UPPER(l_stmt), 'GRANT') > 0
THEN
IF l_schema is NULL
OR (l_schema is NOT NULL AND
(UPPER(l_schema) = 'SYS' OR
UPPER(l_schema) = 'HR')
THEN
l_new_error := NULL;
-- record the fact that we just skipped an error on 'SYS' or 'HR' schemas
-- code not shown here
END IF;
END IF;

dbms_logstdby_context.set_context(name => 'NEW_ERROR', value => l_new_error);

END handle_error_ddl;
/
```

2. Register the error handler with SQL Apply:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP_ERROR ( -
     statement => 'NON_SCHEMA_DDL', -
     schema_name => NULL, -
     object_name => NULL, -
     proc_name => 'SYS.HANDLE_ERROR_DDL');
```

107.4.13 SKIP_TRANSACTION Procedure

This procedure provides a way to skip (ignore) applying transactions to the logical standby database. You can skip specific transactions by specifying transaction identification information.

Syntax

```
DBMS_LOGSTDBY.SKIP_TRANSACTION (
     xidusn          IN NUMBER,
     xidslt          IN NUMBER,
     xidsqn          IN NUMBER,
     con_name_p      VARCHAR2     IN     DEFAULT  NULL
);
```

Parameters

Table 107-19 SKIP_TRANSACTION Procedure Parameters

Parameter	Description
XIDUSN NUMBER	Transaction ID undo segment number of the transaction being skipped
XIDSLT NUMBER	Transaction ID slot number of the transaction being skipped
XIDSQN NUMBER	Transaction ID sequence number of the transaction being skipped
con_name_p	The transaction name.

Usage Notes

If SQL Apply stops due to a particular transaction (for example, a DDL transaction), you can specify that transaction ID and then continue to apply. You can call this procedure multiple times for as many transactions as you want SQL Apply to ignore.

> **WARNING:**
>
> **SKIP_TRANSACTION** is an inherently dangerous operation. Do not invoke this procedure unless you have examined the transaction in question through the **V$LOGMNR_CONTENTS** view and have taken compensating actions at the logical standby database. **SKIP_TRANSACTION** is not the appropriate procedure to invoke to skip DML changes to a table.
>
> To skip a DML failure, use a **SKIP** procedure, such as **SKIP('DML','MySchema','MyFailed Table').** Using the **SKIP_TRANSACTION** procedure for DML transactions may skip changes for other tables, thus logically corrupting them.

- This procedure requires DBA privileges to execute.
- Use the DBA_LOGSTDBY_SKIP_TRANSACTION view to list the transactions that are going to be skipped by SQL Apply.

Exceptions

Table 107-20 SKIP_TRANSACTION Procedure Exceptions

Exception	Description
ORA-01031	Need DBA privileges
ORA-16103	Logical Standby apply must be stopped to allow this operation
ORA-16104	invalid Logical Standby option requested

Examples

To skip a DDL transaction with (XIDUSN, XIDSLT, XIDSQN) of (1.13.1726) you can register a rule as shown in the following example:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP_TRANSACTION (-
     XIDUSN => 1, XIDSLT => 13, XIDSQN => 1726);
```

107.4.14 UNSKIP Procedure

Use the UNSKIP procedure to delete rules specified earlier with the SKIP procedure.

The parameters specified in the UNSKIP procedure must match exactly for it to delete an already-specified rule.

The container_name argument is valid only in a CDB.

Syntax

```
DBMS_LOGSTDBY.UNSKIP (
     stmt                      IN VARCHAR2,
     schema_name               IN VARCHAR2 DEFAULT NULL,
     object_name               IN VARCHAR2 DEFUALT NULL,
     container_name            IN VARCHAR2 DEFAULT NULL);
```

Parameters

The parameter information for the UNSKIP procedure is the same as that described for the SKIP procedure. See Table 107-14 for complete parameter information.

Exceptions

Table 107-21 UNSKIP Procedure Exceptions

Exception	Description
ORA-01031	need DBA privileges to execute this procedure
ORA-16103	Logical Standby apply must be stopped to allow this operation
ORA-16104	invalid Logical Standby option requested

Usage Notes

> **WARNING:**
>
> If DML changes for a table have been skipped and not compensated for, you must follow the call to the **UNSKIP** procedure with a call to the **INSTANTIATE_TABLE** procedure to synchronize this table with those maintained by SQL Apply.

- This procedure requires DBA privileges to execute.
- Wildcards passed in the `schema_name` or the `object_name` parameter are not expanded. The wildcard character is matched at the character level. Thus, you can delete only one specified rule by invoking the `UNSKIP` procedure, and you will need a distinct `UNSKIP` procedure call to delete each rule that was previously specified.

  For example, assume you have specified the following two rules to skip applying DML statements to the `HR.EMPLOYEE` and `HR.EMPTEMP` tables:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP (STMT => 'DML',-
     SCHEMA_NAME => 'HR', -
     OBJECT_NAME => 'EMPLOYEE', -
     PROC_NAME => null);
SQL> EXECUTE DBMS_LOGSTDBY.SKIP (STMT => 'DML',-
     SCHEMA_NAME => 'HR', -
     OBJECT_NAME => 'EMPTEMP', -
     PROC_NAME => null);
```

  In the following example, the wildcard in the `TABLE_NAME` parameter cannot be used to delete the rules that were specified:

```
SQL> EXECUTE DBMS_LOGSTDBY.UNSKIP (STMT => 'DML',-
     SCHEMA_NAME => 'HR', -
     OBJECT_NAME => 'EMP%');
```

  In fact, this `UNSKIP` procedure matches neither of the rules, because the wildcard character in the `TABLE_NAME` parameter is not expanded. Instead, the wildcard character will be used in an exact match to find the corresponding `SKIP` rule.

107.4.15 UNSKIP_ERROR Procedure

Use the `UNSKIP_ERROR` procedure to delete rules specified earlier with the `SKIP_ERROR` procedure.

The parameters specified in the `UNSKIP_ERROR` procedure must match exactly for the procedure to delete an already-specified rule.

The `container_name` argument is valid only in a CDB.

Syntax

```
DBMS_LOGSTDBY.UNSKIP_ERROR (
     stmt                      IN VARCHAR2,
     schema_name               IN VARCHAR2 DEFAULT NULL,
```

```
    object_name              IN VARCHAR2 DEFAULT NULL,
    container_name           IN VARCHAR2 DEFAULT NULL);
```

Parameters

The parameter information for the UNSKIP_ERROR procedure is the same as that described for the SKIP_ERROR procedure. See Table 107-17 for complete parameter information.

Exceptions

Table 107-22 UNSKIP_ERROR Procedure Exceptions

Exception	Description
ORA-01031	Need DBA privileges
ORA-16103	Logical Standby apply must be stopped to allow this operation
ORA-16104	invalid Logical Standby option requested

Usage Notes

- This procedure requires DBA privileges to execute.
- Wildcards passed in the schema_name or the object_name parameters are not expanded. Instead, the wildcard character is treated as any other character and an exact match is made. Thus, you can delete only one specified rule by invoking the UNSKIP_ERROR procedure, and you need a distinct UNSKIP_ERROR procedure call to delete each rule that you previously specified.

  For example, assume you have specified the following two rules to handle the HR.EMPLOYEE and HR.EMPTEMP tables:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP_ERROR (STMT => 'DML',-
     SCHEMA_NAME => 'HR', -
     OBJECT_NAME => 'EMPLOYEE', -
     PROC_NAME => 'hr_employee_handler');
SQL> EXECUTE DBMS_LOGSTDBY.SKIP_ERROR (STMT => 'DML',-
     SCHEMA_NAME => 'HR', -
     OBJECT_NAME => 'EMPTEMP', -
     PROC_NAME => 'hr_tempemp_handler');
```

  In this case, the following UNSKIP procedure cannot be used to delete the rules that you have specified:

```
SQL> EXECUTE DBMS_LOGSTDBY.UNSKIP_ERROR (STMT => 'DML',-
     SCHEMA_NAME => 'HR', -
     OBJECT_NAME => 'EMP%');
```

  In fact, the UNSKIP procedure will match neither of the rules, because the wildcard character in the OBJECT_NAME parameter will not be expanded.

Example

To remove a handler that was previously registered with SQL Apply from getting called on encountering an error, you can issue the following statement:

```
DBMS_LOGSTDBY.UNSKIP_ERROR ( -
      statement => 'NON_SCHEMA_DDL', -
      schema_name => NULL, -
      object_name => NULL);
```

107.4.16 UNSKIP_TRANSACTION Procedure

Use the UNSKIP_TRANSACTION procedure to delete rules specified earlier with the SKIP_TRANSACTION procedure.

The parameters specified in the UNSKIP_TRANSACTION procedure must match exactly for the procedure to delete an already-specified rule.

Syntax

```
DBMS_LOGSTDBY.UNSKIP_TRANSACTION (
     xidusn_p         IN NUMBER,
     xidslt_p         IN NUMBER,
     xidsqn_p         IN NUMBER);
```

Parameters

Table 107-23 UNSKIP_TRANSACTION Procedure Parameters

Parameter	Description
XIDUSN	Transaction ID undo segment number of the transaction being skipped
XIDSLT	Transaction ID slot number of the transaction being skipped
XIDSQN	Transaction ID sequence number of the transaction being skipped

Exceptions

Table 107-24 UNSKIP_TRANSACTION Procedure Exceptions

Exception	Description
ORA-01031	need DBA privileges to execute this procedure
ORA-16103	Logical Standby apply must be stopped to allow this operation
ORA-16104	invalid Logical Standby option requested

Usage Notes

- This procedure requires DBA privileges to execute.
- Query the DBA_LOGSTDBY_SKIP_TRANSACTION view to list the transactions that are going to be skipped by SQL Apply.

Examples

To remove a rule that was originally specified to skip the application of a transaction with (XIDUSN, XIDSLT, XIDSQN) of (1.13.1726) issue the following statement:

```
SQL> DBMS_LOGSTDBY.UNSKIP_TRANSACTION (XIDUSN => 1, XIDSLT => 13, XIDSQN =>
1726);
```

108
DBMS_LOGMNR_D

The DBMS_LOGMNR_D package, one of a set of LogMiner packages, contains two subprograms: the BUILD procedure and the SET_TABLESPACE procedure.

- The BUILD procedure extracts the LogMiner data dictionary to either the redo log files or to a flat file. This information is saved in preparation for future analysis of redo log files using the LogMiner tool.
- The SET_TABLESPACE procedure re-creates all LogMiner tables in an alternate tablespace.

  The **LogMiner data dictionary** consists of the memory data structures and the database tables that are used to store and retrieve information about objects and their versions. It is referred to as the **LogMiner dictionary** throughout the LogMiner documentation.

This chapter contains the following topics:

- Overview
- Security Model
- Summary of DBMS_LOGMNR_D Subprograms

> **See Also:**
>
> *Oracle Database Utilities* for information regarding LogMiner.

108.1 DBMS_LOGMNR_D Overview

LogMiner requires a dictionary to translate object IDs into object names when it returns redo data to you.

LogMiner gives you three options for supplying the dictionary:

- Using the online catalog
- Extracting a LogMiner dictionary to the redo log files
- Extracting a LogMiner dictionary to a flat file

Use the BUILD procedure to extract the LogMiner dictionary to the redo log files or a flat file. If you want to specify the online catalog as the dictionary source, you do so when you start LogMiner with the DBMS_LOGMNR.START_LOGMNR package.

Use the SET_TABLESPACE procedure if you want LogMiner tables to use a tablespace other than the default SYSAUX tablespace.

> **See Also:**
>
> DBMS_LOGMNR for information on the package subprograms used in running a LogMiner session.

108.2 DBMS_LOGMNR_D Security Model

You must have the `EXECUTE_CATALOG_ROLE` role to use the `DBMS_LOGMNR_D` package.

108.3 Summary of DBMS_LOGMNR_D Subprograms

This table lists and briefly describes the DBMS_LOGMNR_D subprograms.

In a multitenant container database (CDB), some subprograms must be called from the root. There may be other differences as well. See the individual subprogram descriptions for details.

Table 108-1 DBMS_LOGMNR_D Package Subprograms

Subprogram	Description
BUILD Procedure	Extracts the LogMiner dictionary to either a flat file or one or more redo log files
SET_TABLESPACE Procedure	Re-creates all LogMiner tables in an alternate tablespace

108.3.1 BUILD Procedure

This procedure extracts the LogMiner data dictionary to either the redo log files or to a flat file.

The following considerations apply to a multitenant container database (CDB) environment.

- In a CDB environment, when you extract to the redo log files, the `BUILD` procedure must be called from the root database. The LogMiner data dictionary for the entire CDB is extracted to the redo log files.
- In a CDB environment, when you extract to flat files, you can mine only one pluggable database (PDB) at a time. You must first explicitly build the flat file dictionary for that specific PDB by running the `BUILD` procedure from it. The LogMiner data dictionary for each PDB for which the `BUILD` procedure is run is extracted to a flat file.
- You cannot add or remove PDBs from a CDB while this procedure is executing.

Syntax

```
DBMS_LOGMNR_D.BUILD (
     dictionary_filename  IN  VARCHAR2,
     dictionary_location  IN  VARCHAR2,
     options              IN  NUMBER);
```

Parameters

Table 108-2 BUILD Procedure Parameters

Parameter	Description
dictionary_filename	Specifies the name of the LogMiner dictionary file.
dictionary_location	Specifies the directory object for the LogMiner dictionary file.
options	Specifies that the LogMiner dictionary is written to either a flat file (STORE_IN_FLAT_FILE) or the redo log files (STORE_IN_REDO_LOGS).

Exceptions

Table 108-3 BUILD Procedure Exceptions

Exception	Description
ORA-01302	Dictionary build options are missing or incorrect. This error is returned under the following conditions: • If the value of the OPTIONS parameter is not one of the supported values (STORE_IN_REDO_LOGS, STORE_IN_FLAT_FILE) or is not specified • If the STORE_IN_REDO_LOGS option is not specified and neither the dictionary_filename nor the dictionary_location parameter is specified • If the STORE_IN_REDO_LOGS option is specified and either the dictionary_filename or the dictionary_location parameter is specified
ORA-01308	Initialization parameter UTL_FILE_DIR is not set.
ORA-01336	Specified dictionary file cannot be opened. This error is returned under the following conditions: • The dictionary file is read-only.

Note:

In prior releases, you used the UTL_FILE_DIR initialization parameter to specify a directory location. However, as of Oracle Database 18*c*, the UTL_FILE_DIR initialization parameter is desupported. It is still supported for backward compatibility, but Oracle recommends that you instead use directory objects.

Table 108-3 (Cont.) BUILD Procedure Exceptions

Exception	Description
ORA-01308	Dictionary directory is not set. This error is returned under the following conditions: • The specified value for the `dictionary_location` is not a directory object. • The specified value for the `dictionary_location` is a directory object that is defined to be a file path that cannot be accessed .

Usage Notes

- To extract the LogMiner dictionary to a flat file, you must supply a filename and location. The location must be specified as a database directory object. (See `CREATE DIRECTORY` in the Oracle Database SQL Language Reference.)

  To extract the LogMiner dictionary to the redo log files, specify only the `STORE_IN_REDO_LOGS` option. The size of the LogMiner dictionary may cause it to be contained in multiple redo log files.

  The combinations of parameters used result in the following behavior:

  – If you do not specify any parameters, an error is returned.

  – If you specify a filename and location, without any options, the LogMiner dictionary is extracted to a flat file with that name.

  – If you specify a filename and location, as well as the `STORE_IN_FLAT_FILE` option, the LogMiner dictionary is extracted to a flat file with the specified name.

  – If you do not specify a filename and location, but do specify the `STORE_IN_REDO_LOGS` option, the LogMiner dictionary is extracted to the redo log files.

  – If you specify a filename and location, as well as the `STORE_IN_REDO_LOGS` option, an error is returned.

  – If you do not specify a filename and location, but do specify the `STORE_IN_FLAT_FILE` option, an error is returned.

- Ideally, the LogMiner dictionary file will be created after all database dictionary changes have been made and prior to the creation of any redo log files that are to be analyzed. As of Oracle9*i* release 1 (9.0.1), you can use LogMiner to dump the LogMiner dictionary to the redo log files or a flat file, perform DDL operations, and dynamically apply the DDL changes to the LogMiner dictionary.
- The database must be open when you run the `DBMS_LOGMNR_D.BUILD` procedure.
- When extracting a LogMiner dictionary to a flat file, the procedure queries the dictionary tables of the current database and creates a text-based file containing the contents of the tables. To extract a LogMiner dictionary to a flat file, the following conditions must be met:

  – You must specify a directory for use by the PL/SQL procedure. To do so, first create an Oracle directory object with a pathname that specifies where the dictionary file is to be generated. For example:

```
create directory my_dictionary_dir as '/oracle/dictionary';
```

Be aware that the DDL_DICT_TRACKING option to the DBMS_LOGMNR.START_LOGMNR procedure is not supported for flat file dictionaries created prior to Oracle9*i*. If you attempt to use the DDL_DICT_TRACKING option with a LogMiner database extracted to a flat file prior to Oracle9*i*, the ORA-01330 error (problem loading a required build table) is returned.

- To extract a LogMiner dictionary file to the redo log files, the following conditions must be met:
  - The DBMS_LOGMNR_D.BUILD procedure must be run on a system that is running Oracle9*i* or later.
  - Archivelog mode must be enabled in order to generate usable redo log files.
  - The COMPATIBLE parameter in the initialization parameter file must be set to 9.2.0 or higher.
  - The database to which LogMiner is attached must be Oracle9*i* or later.

  In addition, supplemental logging (at least the minimum level) should be enabled to ensure that you can take advantage of all the features that LogMiner offers.

Examples

Example 1: Extracting the LogMiner Dictionary to a Flat File

The following example extracts the LogMiner dictionary file to a flat file named dictionary.ora in a specified path (/oracle/database).

```
SQL> create directory my_dictionary_dir as '/oracle/database';
SQL> EXECUTE dbms_logmnr_d.build(dictionary_location=>my_dictionary_dir, -
                                 dictionary_filename=>'dictionary.ora', -
                                options => dbms_logmnr_d.store_in_flat_file);
```

Example 2: Extracting the LogMiner Dictionary to the Redo Log Files

The following example extracts the LogMiner dictionary to the redo log files.

```
SQL> EXECUTE dbms_logmnr_d.build( -
     options => dbms_logmnr_d.store_in_redo_logs);
```

108.3.2 SET_TABLESPACE Procedure

This procedure moves LogMiner tables from the default SYSAUX tablespace to an alternate tablespace.

By default, all LogMiner tables are created to use the SYSAUX tablespace. However, it may be desirable to have LogMiner tables use an alternate tablespace. Use this procedure to move LogMiner tables to this alternate tablespace

In a CDB, only the LogMiner metadata in the local container is moved to the requested tablespace.

Syntax

```
DBMS_LOGMNR_D.SET_TABLESPACE (
     new_tablespace        IN VARCHAR2);
```

Parameters

Table 108-4 SET_TABLESPACE Parameter

Parameter	Description
new_tablespace	A string naming a preexisting tablespace. To move all LogMiner tables to employ this tablespace, supply this parameter.

Usage Notes

- Users upgrading from earlier versions of Oracle Database may find LogMiner tables in the SYSTEM tablespace. Oracle encourages such users to consider using the SET_TABLESPACE procedure to move the tables to the SYSAUX tablespace once they are confident that they will not be downgrading to an earlier version of Oracle Database.
- Users of this routine must supply an existing tablespace.

Example: Using the DBMS_LOGMNR_D.SET_TABLESPACE Procedure

The following example shows the creation of an alternate tablespace and execution of the DBMS_LOGMNR_D.SET_TABLESPACE procedure.

```
SQL> CREATE TABLESPACE  logmnrts$ datafile '/usr/oracle/dbs/logmnrts.f'
     SIZE 25 M REUSE AUTOEXTEND ON MAXSIZE UNLIMITED;

SQL> EXECUTE dbms_logmnr_d.set_tablespace('logmnrts$');
```

109
DBMS_LOGSTDBY_CONTEXT

As of Oracle Database 12*c* release 1 (12.1), SQL Apply processes have access to a context namespace called `LSBY_APPLY_CONTEXT`. You can use the procedures provided in the `DBMS_LOGSTDBY_CONTEXT` package to set and retrieve various parameters associated with `LSBY_APPLY_CONTEXT`. This is useful when writing skip procedures that are registered with SQL Apply using the `DBMS_LOGSTBDY.SKIP` and `DBMS_LOGSTDBY.SKIP_ERROR` procedures.

This chapter contains the following topics:

- Overview
- Security Model
- Summary of DBMS_LOGSTDBY_CONTEXT Subprograms

> **See Also:**
>
> *Oracle Data Guard Concepts and Administration* for more information about SQL Apply and logical standby databases

109.1 DBMS_LOGSTDBY_CONTEXT Overview

SQL Apply processes have access to a context namespace called `LSBY_APPLY_CONTEXT`.

The following table lists the predefined parameters associated with `LSBY_APPLY_CONTEXT` that you can set and retrieve by using the procedures provided in the `DBMS_LOGSTDBY_CONTEXT` package. The ability to set and retrieve the parameters in this way is useful when writing skip procedures that are registered with SQL Apply using the `DBMS_LOGSTBDY.SKIP` and `DBMS_LOGSTDBY.SKIP_ERROR` procedures.

Table 109-1 Predefined Parameters of Namespace LSBY_APPLY_CONTEXT

Parameter	Description
`STATEMENT`	First 4000 bytes of the statement that the Apply process is processing.
`STATEMENT_TYPE`	See Table 107-15 for a list of various statement types.
`PACKAGE_SCHEMA`	Schema that owns the PL/SQL package being processed (if applicable).
`PACKAGE_NAME`	Name of the PL/SQL package being processed (if applicable).
`PROCEDURE_NAME`	Name of the PL/SQL procedure being processed (if applicable).
`CURRENT_SCHEMA`	Current schema in effect when the DDL or PL/SQL procedure was executed at the primary.
`XIDUSN`	XIDUSN of the transaction at the primary database.

Table 109-1 (Cont.) Predefined Parameters of Namespace LSBY_APPLY_CONTEXT

Parameter	Description
XIDSLT	XIDSLT of the transaction at the primary database.
XIDSQN	XIDSQN of the transaction at the primary database.
SCHEMA	Schema that owns the object being processed by SQL Apply (in the case of DML or DDL operations).
NAME	Object name being processed by SQL Apply (in case of DML or DDL operations).
CONTAINER_NAME	Container where the target object or the PL/SQL procedure resides (in the case of a multitenant container database (CDB)).
ERROR	Text of the original error encountered by the SQL Apply process (if applicable).
NEW_ERROR	Text of the new error to be raised by the SQL Apply process (if applicable, See the DBMS_LOGSTDBY SKIP_ERROR Procedure).
NEW_STMT	Text of the replacement statement that SQL Apply must execute (If applicable, See the DBMS_LOGSTDBY SKIP Procedure).
SKIP_ACTION	The skip action to be performed by SQL Apply (See the DBMS_LOGSTDBY SKIP Procedure).

109.2 DBMS_LOGSTDBY_CONTEXT Security Model

The security model for the DBMS_LOGSTDBY_CONTEXT package is the same as for the DBMS_LOGSTDBY package.

> **See Also:**
>
> DBMS_LOGSTDBY

109.3 Summary of DBMS_LOGSTDBY_CONTEXT Subprograms

This table lists and briefly describes the DBMS_LOGSTDBY_CONTEXT package subprograms.

Table 109-2 DBMS_LOGSTDBY_CONTEXT Package Subprograms

Subprogram	Description
CLEAR_ALL_CONTEXT Procedure	Clears all parameters contained within namespace LSBY_APPLY_CONTEXT.
CLEAR_CONTEXT Procedure	Clears the specific parameter.
GET_CONTEXT Procedure	Retrieves the value for the specified parameter.

Table 109-2 (Cont.) DBMS_LOGSTDBY_CONTEXT Package Subprograms

Subprogram	Description
SET_CONTEXT Procedure	Sets the named parameter with the specified value.

109.3.1 CLEAR_ALL_CONTEXT Procedure

This procedure clears all parameters contained within namespace `LSBY_APPLY_CONTEXT`.

Syntax

```
DBMS_LOGSTDBY_CONTEXT.CLEAR_ALL_CONTEXT;
```

Parameters

None

109.3.2 CLEAR_CONTEXT Procedure

This procedure clears the specific parameter.

Syntax

```
DBMS_LOGSTDBY_CONTEXT.CLEAR_CONTEXT (
   name            IN VARCHAR2);
```

Parameters

Table 109-3 *CLEAR_CONTEXT Procedure Parameters*

Parameter	Description
name	Name of the parameter to be cleared.

109.3.3 GET_CONTEXT Procedure

This procedure retrieves the value for the specified parameter.

Syntax

```
DBMS_LOGSTDBY_CONTEXT.GET_CONTEXT (
   name            IN VARCHAR2,
   value           OUT VARCHAR2);
```

Parameters

Table 109-4 *GET_CONTEXT Procedure Parameters*

Parameter	Description
name	Name of the parameter.
value	The value retrieved for the parameter.

109.3.4 SET_CONTEXT Procedure

This procedure sets the named parameter with the specified value.

Syntax

```
DBMS_LOGSTDBY_CONTEXT.SET_CONTEXT (
   name            IN VARCHAR2
   value           IN VARCHAR2);
```

Parameters

Table 109-5 *SET_CONTEXT Procedure Parameters*

Parameter	Description
name	Name of the parameter to be set.
value	Value to be assigned to the parameter being set.

110
DBMS_MEMOPTIMIZE

The DBMS_MEMOPTIMIZE package provides the interface for managing the Memoptimized Rowstore data buffered in the large pool and the memoptimize pool.

This chapter contains the following topics:

- DBMS_MEMOPTIMIZE Overview
- Summary of DBMS_MEMOPTIMIZE Subprograms

110.1 DBMS_MEMOPTIMIZE Overview

The DBMS_MEMOPTIMIZE package provides the interface for managing Memoptimized Rowstore data buffered in the large pool and the memoptimize pool.

The Memoptimized Rowstore provides the following functionality:

- Fast Ingest

  Fast ingest optimizes the processing of high-frequency, single-row data inserts. Fast ingest uses the large pool in the SGA for buffering the inserts before writing them to disk.

- Fast Lookup

  Fast lookup enables fast retrieval of data for high-frequency queries. Fast lookup uses a separate memory area in the SGA called the *memoptimize pool* for buffering data queried from tables.

The DBMS_MEMOPTIMIZE package provides the following operations related to the Memoptimized Rowstore:

- Fast ingest operations:
  - Provide the low high-water mark (low HWM) of the sequence numbers of rows that have been successfully written from the large pool to disk across all the sessions.
  - Provide the high-water mark (HWM) sequence number of the row that has been written to the large pool for the current session.
  - Flush all the fast ingest data from the large pool to disk for the current session.
- Fast lookup operations:
  - Remove data for a table from the memoptimize pool.
  - Populate data for a table in the memoptimize pool.

110.2 Summary of DBMS_MEMOPTIMIZE Subprograms

This table lists the DBMS_MEMOPTIMIZE subprograms and briefly describes them.

Table 110-1 DBMS_MEMOPTIMIZE Package Subprograms Related to Fast Ingest

Procedure	Description
GET_APPLY_HWM_SEQID Function	Returns the low high-water mark (low HWM) of the sequence numbers of rows that have been successfully written to disk globally across all the sessions.
GET_WRITE_HWM_SEQID Function	Returns the high-water mark (HWM) sequence number of the row that has been written to the large pool for the current session.
WRITE_END Procedure	Flushes all the fast ingest data from the large pool to disk for the current session.

Table 110-2 DBMS_MEMOPTIMIZE Package Subprograms Related to Fast Lookup

Procedure	Description
DROP_OBJECT Procedure	Removes data for a table from the memoptimize pool.
POPULATE Procedure	Populates data for a table in the memoptimize pool.

110.2.1 DROP_OBJECT Procedure

This procedure removes data for a table from the memoptimize pool.

Syntax

```
DBMS_MEMOPTIMIZE.DROP_OBJECT (
   schema_name         IN VARCHAR2,
   table_name          IN VARCHAR2,
   partition_name      IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 110-3 DROP_OBJECT Procedure Parameters

Parameter	Description
schema_name	Name of the schema.
table_name	Name of the table for which the data needs to be removed from the memoptimize pool.
partition_name	Name of the table partition for which the data needs to be removed from the memoptimize pool. This is an optional parameter and its default value is NULL.

110.2.2 GET_APPLY_HWM_SEQID Function

This function returns the low high-water mark (low HWM) of sequence numbers of the records that have been successfully written to disk across all the sessions.

Syntax

```
DBMS_MEMOPTIMIZE.GET_APPLY_HWM_SEQID
  RETURN number;
```

Return Value

Returns the low high-water mark (low HWM) of sequence numbers of the records that have been successfully written to disk across all the sessions.

110.2.3 GET_WRITE_HWM_SEQID Function

This function returns the high-water mark (HWM) sequence number of the record that has been written to the large pool for the current session.

Syntax

```
DBMS_MEMOPTIMIZE.GET_WRITE_HWM_SEQID
  RETURN number;
```

Return Value

Returns the high-water mark (HWM) sequence number of the record that has been written to the large pool for the current session.

110.2.4 POPULATE Procedure

This procedure populates the data for a table in the memoptimize pool.

Syntax

```
DBMS_MEMOPTIMIZE.POPULATE (
   schema_name        IN VARCHAR2,
   table_name         IN VARCHAR2,
   partition_name     IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 110-4 POPULATE Procedure Parameters

Parameter	Description
schema_name	Name of the schema.
table_name	Name of the table for which the data needs to be populated in the memoptimize pool.

Table 110-4 (Cont.) POPULATE Procedure Parameters

Parameter	Description
`partition_name`	Name of the table partition for which the data needs to be populated in the memoptimize pool. This is an optional parameter and its default value is `NULL`.

110.2.5 WRITE_END Procedure

This procedure flushes all the fast ingest data from the large pool to disk for the current session.

Syntax

```
DBMS_MEMOPTIMIZE.WRITE_END;
```

111
DBMS_MEMOPTIMIZE_ADMIN

The DBMS_MEMOPTIMIZE_ADMIN package provides the interface for flushing the Memoptimized Rowstore data buffered in the large pool to disk.

This chapter contains the following topics:

- DBMS_MEMOPTIMIZE_ADMIN Overview
- Summary of DBMS_MEMOPTIMIZE_ADMIN Subprograms

111.1 DBMS_MEMOPTIMIZE_ADMIN Overview

The DBMS_MEMOPTIMIZE_ADMIN package provides the interface for flushing the Memoptimized Rowstore data that is buffered in the large pool to disk.

The Memoptimized Rowstore provides the following functionality:

- Fast Ingest

  Fast ingest optimizes the processing of high-frequency, single-row data inserts. Fast ingest uses the large pool in the SGA for buffering the inserts before writing them to disk.

- Fast Lookup

  Fast lookup enables fast retrieval of data for high-frequency queries. Fast lookup uses a separate memory area in the SGA called the *memoptimize pool* for buffering the data queried from tables.

The DBMS_MEMOPTIMIZE_ADMIN package provides the following operation related to fast ingest of the Memoptimized Rowstore:

- Flush fast ingest data from the large pool to disk for all sessions.

111.2 Summary of DBMS_MEMOPTIMIZE_ADMIN Subprograms

This table lists the DBMS_MEMOPTIMIZE_ADMIN subprograms and briefly describes them.

Table 111-1 DBMS_MEMOPTIMIZE_ADMIN Package Subprograms

Procedure	Description
WRITES_FLUSH Procedure	Flushes all the fast ingest data of the Memoptimize Rowstore from the large pool to disk for all the sessions.

111.2.1 WRITES_FLUSH Procedure

This procedure flushes all the fast ingest data of the Memoptimized Rowstore from the large pool to disk for all the sessions.

Syntax

```
DBMS_MEMOPTIMIZE_ADMIN.WRITES_FLUSH;
```

112
DBMS_METADATA

The DBMS_METADATA package provides a way for you to retrieve metadata from the database dictionary as XML or creation DDL and to submit the XML to re-create the object.

> **See Also:**
>
> *Oracle Database Utilities* for more information and for examples of using the DBMS_METADATA package.

This chapter contains the following topics:

- Overview
- Security Model
- Rules and Limits
- Data Structures - Object and Table Types
- Subprogram Groupings
  - Subprograms for Retrieving Multiple Objects From the Database
  - Subprograms for Submitting XML to the Database
- Summary of All DBMS_METADATA Subprograms

112.1 DBMS_METADATA Overview

You can use the DBMS_METADATA package to retrieve metadata and to submit XML.

Retrieving Metadata

If you are retrieving metadata, you can specify:

- The kind of object to be retrieved. This can be either a particular object type (such as a table, index, or procedure) or a heterogeneous collection of object types that form a logical unit (such as a database export or schema export).
- Optional selection criteria, such as owner or name.
- Parse items (attributes of the returned objects to be parsed and returned separately).
- Optional transformations on the output, implemented by XSLT (Extensible Stylesheet Language Transformation) scripts. By default the output is represented in XML, but you can specify transformations (into SQL DDL, for example), which are implemented by XSLT stylesheets stored in the database or externally.

DBMS_METADATA provides the following retrieval interfaces:

- For programmatic use: OPEN, SET_FILTER, SET_COUNT, GET_QUERY, SET_PARSE_ITEM, ADD_TRANSFORM, SET_TRANSFORM_PARAM, SET_REMAP_PARAM, FETCH_xxx, and CLOSE retrieve multiple objects.
- For use in SQL queries and for browsing: GET_XML, GET_DDL and GET_SXML return metadata for a single named object. The GET_DEPENDENT_XML, GET_DEPENDENT_DDL, GET_GRANTED_XML, and GET_GRANTED_DDL interfaces return metadata for one or more dependent or granted objects. These procedures do not support heterogeneous object types.

Submitting XML

If you are submitting XML, you specify:

- The type of object
- Optional transform parameters to modify the object (for example, changing the object's owner)
- Parse items (attributes of the submitted objects to be parsed and submitted separately)
- Whether to execute the operation or simply return the generated DDL

DBMS_METADATA provides a programmatic interface for submission of XML. It is comprised of the following procedures: OPENW, ADD_TRANSFORM, SET_TRANSFORM_PARAM, SET_REMAP_PARAM, SET_PARSE_ITEM, CONVERT, PUT, and CLOSE.

112.2 DBMS_METADATA Security Model

The DBMS_METADATA package considers a privileged user to be one who is connected as user SYS or who has the SELECT_CATALOG_ROLE role.

The object views of the Oracle metadata model implement security as follows:

- Nonprivileged users can see the metadata of only their own objects.
- Nonprivileged users can also retrieve public synonyms, system privileges granted to them, and object privileges granted to them or by them to others. This also includes privileges granted to PUBLIC.
- If callers request objects they are not privileged to retrieve, no exception is raised; the object is simply not retrieved.
- If nonprivileged users are granted some form of access to an object in someone else's schema, they will be able to retrieve the grant specification through the Metadata API, but not the object's actual metadata.
- In stored procedures, functions, and definers-rights packages, roles (such as SELECT_CATALOG_ROLE) are disabled. Therefore, such a PL/SQL program can only fetch metadata for objects in its own schema. If you want to write a PL/SQL program that fetches metadata for objects in a different schema (based on the invoker's possession of SELECT_CATALOG_ROLE), you must make the program invokers-rights.
- For all objects that have passwords, except database links (for example, users and roles), the following rules apply:
  - A user who has the SELECT_CATALOG_ROLE can see all metadata for an object except the passwords for that object.

  - The SYS user, users who have the EXP_FULL_DATABASE role, and users who own an object can see all metadata for that object, including passwords.

- For database links the password is never displayed. For security reasons Oracle restricts visibility of the password value to SYS users who query the link$.passwordx column directly. Instead of the password, DBMS_METADATA returns the following invalid syntax:

  ```
  IDENTIFIED BY VALUES ':1'
  ```

  A user who knows the password of the database link can manually replace the :1 with the password.

112.3 Rules and Limits

In an Oracle Shared Server (OSS) environment, the DBMS_METADATA package must disable session migration and connection pooling.

This results in any shared server process that is serving a session running the package to effectively become a default, dedicated server for the life of the session. You should ensure that sufficient shared servers are configured when the package is used and that the number of servers is not artificially limited by too small a value for the MAX_SHARED_SERVERS initialization parameter.

112.4 DBMS_METADATA Data Structures - Object and Table Types

The DBMS_METADATA package defines, in the SYS schema, the OBJECT and TABLE types shown in this code.

```
CREATE TYPE sys.ku$_parsed_item AS OBJECT (
  item            VARCHAR2(30),
  value           VARCHAR2(4000),
  object_row      NUMBER )
/

CREATE PUBLIC SYNONYM ku$_parsed_item FOR sys.ku$_parsed_item;

CREATE TYPE sys.ku$_parsed_items IS TABLE OF sys.ku$_parsed_item
/

CREATE PUBLIC SYNONYM ku$_parsed_items FOR sys.ku$_parsed_items;

CREATE TYPE sys.ku$_ddl AS OBJECT (
   ddlText        CLOB,
parsedItems sys.ku$_parsed_items )
/

CREATE PUBLIC SYNONYM ku$_ddl FOR sys.ku$_ddl;

CREATE TYPE sys.ku$_ddls IS TABLE OF sys.ku$_ddl
/

CREATE PUBLIC SYNONYM ku$_ddls FOR sys.ku$_ddls;

CREATE TYPE sys.ku$_multi_ddl AS OBJECT (
   object_row     NUMBER,
   ddls           sys.ku$_ddls )
```

```
/

CREATE OR REPLACE PUBLIC SYNONYM ku$_multi_ddl FOR sys.ku$_multi_ddl;

CREATE TYPE sys.ku$_multi_ddls IS TABLE OF sys.ku$_multi_ddl;
/

CREATE OR REPLACE PUBLIC SYNONYM ku$_multi_ddls FOR
                          sys.ku$_multi_ddls;

CREATE TYPE sys.ku$_ErrorLine IS OBJECT (
   errorNumber    NUMBER,
   errorText      VARCHAR2(2000) )
/

CREATE PUBLIC SYNONYM ku$_ErrorLine FOR sys.ku$_ErrorLine;

CREATE TYPE sys.ku$_ErrorLines IS TABLE OF sys.ku$_ErrorLine
/
CREATE PUBLIC SYNONYM ku$ErrorLines FOR sys.ku$_ErrorLines;

CREATE TYPE sys.ku$_SubmitResult AS OBJECT (
   ddl          sys.ku$_ddl,
   errorLines   sys.ku$_ErrorLines );
/

CREATE TYPE sys.ku$_SubmitResults IS TABLE OF sys.ku$_SubmitResult
/

CREATE PUBLIC SYNONYM ku$_SubmitResults FOR sys.ku$_SubmitResults;
```

> **Note:**
>
> The maximum size of the `VARCHAR2`, `NVARCHAR2`, and `RAW` datatypes has been increased to 32 KB when the `COMPATIBLE` initialization parameter is set to 12.0 and the `MAX_STRING_SIZE` initialization parameter is set to `EXTENDED`. The `DBMS_METADATA` package supports this increased size unless the version of the metadata is earlier than Oracle Database 12*c* Release 1 (12.1).

112.5 DBMS_METADATA Subprogram Groupings

The `DBMS_METADATA` subprograms retrieve objects from, and submit XML to, a database. Some subprograms are used for both activities, while others are used only for retrieval or only for submission.

- Table 112-1 provides a summary, in alphabetical order, of `DBMS_METADATA` subprograms used to retrieve multiple objects from a database.
- Table 112-2 provides a summary, in alphabetical order, of `DBMS_METADATA` subprograms used to submit XML metadata to a database.

112.5.1 DBMS_METADATA Subprograms for Retrieving Multiple Objects From the Database

DBMS_METADATA uses these subprograms used for retrieving multiple objects from the database.

Table 112-1 DBMS_METADATA Subprograms for Retrieving Multiple Objects

Subprogram	Description
ADD_TRANSFORM Function	Specifies a transform that FETCH_xxx applies to the XML representation of the retrieved objects
CLOSE ProcedureCLOSE Procedure	Invalidates the handle returned by OPEN and cleans up the associated state
FETCH_xxx Functions and Procedures	Returns metadata for objects meeting the criteria established by OPEN, SET_FILTER, SET_COUNT, ADD_TRANSFORM, and so on
GET_QUERY Function	Returns the text of the queries that are used by FETCH_xxx
GET_xxx Functions	Fetches the metadata for a specified object as XML, SXML, or DDL, using only a single call
OPEN Function	Specifies the type of object to be retrieved, the version of its metadata, and the object model
SET_COUNT Procedure	Specifies the maximum number of objects to be retrieved in a single FETCH_xxx call
SET_FILTER Procedure	Specifies restrictions on the objects to be retrieved, for example, the object name or schema
SET_PARSE_ITEM Procedure	Enables output parsing by specifying an object attribute to be parsed and returned
SET_TRANSFORM_PARAM and SET_REMAP_PARAM Procedures	Specifies parameters to the XSLT stylesheets identified by transform_handle

112.5.2 DBMS_METADATA Subprograms for Submitting XML to the Database

DBMS_METADATA uses these subprograms for submitting XML to the database.

Table 112-2 DBMS_METADATA Subprograms for Submitting XML

Subprogram	Description
ADD_TRANSFORM Function	Specifies a transform for the XML documents
CLOSE ProcedureCLOSE Procedure	Closes the context opened with OPENW
CONVERT Functions and Procedures	Converts an XML document to DDL
OPENW Function	Opens a write context
PUT Function	Submits an XML document to the database
SET_PARSE_ITEM Procedure	Specifies an object attribute to be parsed

Table 112-2 (Cont.) DBMS_METADATA Subprograms for Submitting XML

Subprogram	Description
SET_TRANSFORM_PARAM and SET_REMAP_PARAM Procedures	SET_TRANSFORM_PARAM specifies a parameter to a transform SET_REMAP_PARAM specifies a remapping for a transform

112.6 Summary of All DBMS_METADATA Subprograms

This table lists the DBMS_METADATA subprograms and briefly describes them.

Table 112-3 DBMS_METADATA Package Subprograms

Subprogram	Description
ADD_TRANSFORM Function	Specifies a transform that FETCH_xxx applies to the XML representation of the retrieved objects
CLOSE ProcedureCLOSE Procedure	Invalidates the handle returned by OPEN and cleans up the associated state
CONVERT Functions and Procedures	Converts an XML document to DDL
FETCH_xxx Functions and Procedures	Returns metadata for objects meeting the criteria established by OPEN, SET_FILTER, SET_COUNT, ADD_TRANSFORM, and so on
GET_xxx Functions	Fetches the metadata for a specified object as XML, SXML, or DDL, using only a single call
GET_QUERY Function	Returns the text of the queries that are used by FETCH_XXX
OPEN Function	Specifies the type of object to be retrieved, the version of its metadata, and the object model
OPENW Function	Opens a write context
PUT Function	Submits an XML document to the database
SET_COUNT Procedure	Specifies the maximum number of objects to be retrieved in a single FETCH_XXX call
SET_FILTER Procedure	Specifies restrictions on the objects to be retrieved, for example, the object name or schema
SET_PARSE_ITEM Procedure	Enables output parsing by specifying an object attribute to be parsed and returned
SET_TRANSFORM_PARAM and SET_REMAP_PARAM Procedures	Specifies parameters to the XSLT stylesheets identified by transform_handle

112.6.1 ADD_TRANSFORM Function

The DBMS_METADATA.ADD_TRANSFORM function is used for both retrieval and submission.

- When this procedure is used to retrieve objects, it specifies a transform that FETCH_xxx applies to the XML representation of the retrieved objects.

- When used to submit objects, it specifies a transform that `CONVERT` or `PUT` applies to the XML representation of the submitted objects. It is possible to add more than one transform.

> **See Also:**
>
> – Subprograms for Retrieving Multiple Objects From the Database
> – Subprograms for Submitting XML to the Database
> – "SET_TRANSFORM_PARAM and SET_REMAP_PARAM Procedures" for information about how to modify and customize transform output

Syntax

```
DBMS_METADATA.ADD_TRANSFORM (
   handle       IN NUMBER,
   name         IN VARCHAR2,
   encoding     IN VARCHAR2 DEFAULT NULL,
   object_type  IN VARCHAR2 DEFAULT NULL)
 RETURN NUMBER;
```

Parameters

Table 112-4 ADD_TRANSFORM Function Parameters

Parameters	Description
`handle`	The handle returned from `OPEN` when this transform is used to retrieve objects. Or the handle returned from `OPENW` when this transform is used in the submission of XML metadata.
`name`	The name of the transform. The name can be an internal keyword like `DDL` to use internally stored stylesheets. If the name contains a colon, it is interpreted as `directory_object_name:file_name` of a user-supplied Extensible Stylesheet Language Transformation (XSLT) script. Otherwise, name designates a transform implemented by `DBMS_METADATA`. See Table 112-5 for descriptions of available transforms.
`encoding`	The name of the Globalization Support character set in which the stylesheet pointed to by name is encoded. This is only valid if name is a URL. If left NULL and the URL is external to the database, UTF-8 encoding is assumed. If left `NULL` and the URL is internal to the database (that is, it begins with `/oradb/`), then the encoding is assumed to be the database character set.

Table 112-4 (Cont.) ADD_TRANSFORM Function Parameters

Parameters	Description
object_type	The definition of this parameter depends upon whether you are retrieving objects or submitting XML metadata. 1. When you use ADD_TRANFORM to retrieve objects, the following definition of object_type applies: Designates the object type to which the transform applies. (Note that this is an object type name, not a path name.) By default the transform applies to the object type of the OPEN handle. When the OPEN handle designates a heterogeneous object type, the following behavior can occur: • if object_type is omitted, the transform applies to all object types within the heterogeneous collection • if object_type is specified, the transform only applies to that specific object type within the collection If you omit this parameter you can add the DDL transform to all objects in a heterogeneous collection with a single call. If you supply this parameter, you can add a transform for a specific object type. 2. When you use ADD_TRANSFORM in the submission of XML metadata, this parameter is the object type to which the transform applies. By default, it is the object type of the OPENW handle. Because the OPENW handle cannot designate a heterogeneous object type, the caller would normally leave this parameter NULL in the ADD_TRANSFORM calls.

The following table describes the transforms available on the ADD_TRANSFORM function.

Because new transforms are occasionally added, you might want to query the DBMS_METADATA_TRANSFORMS view to see all valid Oracle-supplied transforms for specific object types.

Table 112-5 Transforms Available on ADD_TRANSFORM Function

Object Type	Transform Name	Input Doc Type	Output Doc Type	Description
All	DDL	XML	DDL	Convert XML to SQL to create the object
All	MODIFY	XML	XML	Modify XML document according to transform parameters
Subset	SXML	XML	SXML	Convert XML to SXML
Subset	MODIFYSXML	SXML	SXML	Modify SXML document according to transform parameters
Subset	SXMLDDL	SXML	DDL	Convert SXML to DDL

Table 112-5 (Cont.) Transforms Available on ADD_TRANSFORM Function

Object Type	Transform Name	Input Doc Type	Output Doc Type	Description
Subset	ALTERXML	SXML difference document	ALTER_XML	Generate ALTER_XML from SXML difference document. (See the DBMS_METADATA_DIFF PL/SQL package for more information about SXML difference format.) The following parameters are valid for the ALTERXML transform: • XPATH - The XPATH of the object being altered • NAME - Name of the object being altered • ALTERABLE - Affirms that the object can be altered. If the object cannot be altered, a NOT_ALTERABLE element is inserted whose value indicates the reason. • CLAUSE_TYPE - The type of clause (for example, ADD_COLUMN) • COLUMN_ATTRIBUTE - The attribute being modified • CONSTRAINT_TYPE - The type of constraint (for example, UNIQUE or PRIMARY)
Subset	ALTERDDL	ALTER_XML	ALTER_DDL	Convert ALTER_XML to ALTER_DDL

Return Values

The opaque handle that is returned is used as input to SET_TRANSFORM_PARAM and SET_REMAP_PARAM. Note that this handle is different from the handle returned by OPEN or OPENW; it refers to the transform, not the set of objects to be retrieved.

Usage Notes

- With no transforms added, objects are returned by default as XML documents. You call ADD_TRANSFORM to specify the XSLT stylesheets to be used to transform the returned XML documents.
- You can call ADD_TRANSFORM more than once to apply multiple transforms to XML documents. The transforms are applied in the order in which they were specified, the output of the first transform being used as input to the second, and so on.
- The output of a DDL transform is *not* an XML document. Therefore, no transform should be added after the DDL transform.
- Each transform expects a certain format XML document as input. If the input document is unspecified, metadata XML format is assumed.
- When the ALTERXML transform is used, parse items are returned in a PARSE_LIST element of the ALTER_XML document. Each PARSE_LIST_ITEM element contains an ITEM and a VALUE. For example:

```
<PARSE_LIST>
 <PARSE_LIST_ITEM>
  <ITEM>XPATH</ITEM>
  <VALUE>/sxml:TABLE/sxml:RELATIONAL_TABLE/sxml:COL_LIST/
sxml:COL_LIST_ITEM[14]</VALUE>
 </PARSE_LIST_ITEM>
 <PARSE_LIST_ITEM>
  <ITEM>NAME</ITEM>
  <VALUE>Z1</VALUE>
 </PARSE_LIST_ITEM>
 <PARSE_LIST_ITEM>
  <ITEM>CLAUSE_TYPE</ITEM>
  <VALUE>ADD_COLUMN</VALUE>
 </PARSE_LIST_ITEM>
 <PARSE_LIST_ITEM>
  <ITEM>COLUMN_ATTRIBUTE</ITEM>
  <VALUE>NOT_NULL</VALUE>
 </PARSE_LIST_ITEM>
</PARSE_LIST>
```

Exceptions

- `INVALID_ARGVAL`. A `NULL` or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- `INVALID_OPERATION`. `ADD_TRANSFORM` was called after the first call to `FETCH_xxx` for the `OPEN` context. After the first call to `FETCH_xxx` is made, no further calls to `ADD_TRANSFORM` for the current `OPEN` context are permitted.
- `INCONSISTENT_ARGS`. The arguments are inconsistent. Possible inconsistencies include the following:
  - `encoding` is specified even though name is not a URL.
  - `object_type` is not part of the collection designated by handle.

112.6.2 CLOSE Procedure

This procedure is used for both retrieval and submission. This procedure invalidates the handle returned by `OPEN` (or `OPENW`) and cleans up the associated state.

> **See Also:**
>
> For more information about related subprograms:
>
> - Subprograms for Retrieving Multiple Objects From the Database
> - Subprograms for Submitting XML to the Database

Syntax

```
DBMS_METADATA.CLOSE (
   handle  IN NUMBER);
```

Parameters

Table 112-6 CLOSE Procedure Parameters

Parameter	Description
handle	The handle returned from OPEN (or OPENW).

Usage Notes

> **Note:**
>
> The following notes apply only to object retrieval

You can prematurely terminate the stream of objects established by OPEN or (OPENW).

- If a call to FETCH_xxx returns NULL, indicating no more objects, a call to CLOSE is made transparently. In this case, you can still call CLOSE on the handle and not get an exception. (The call to CLOSE is not required.)
- If you know that only one specific object will be returned, you should explicitly call CLOSE after the single FETCH_xxx call to free resources held by the handle.

Exceptions

- INVALID_ARGVAL. The value for the handle parameter is NULL or invalid.

112.6.3 CONVERT Functions and Procedures

The DBMS_METADATA.CONVERT functions and procedures transform input XML documents.

The CONVERT functions return creation DDL. The CONVERT procedures return either XML or DDL, depending on the specified transforms.

> **See Also:**
>
> - Subprograms for Submitting XML to the Database

Syntax

The CONVERT functions are as follows:

```
DBMS_METADATA.CONVERT (
   handle   IN NUMBER,
   document IN sys.XMLType)
 RETURN sys.ku$_multi_ddls;

DBMS_METADATA.CONVERT (
  handle   IN NUMBER,
```

```
  document IN CLOB)
 RETURN sys.ku$_multi_ddls;
```

The CONVERT procedures are as follows:

```
DBMS_METADATA.CONVERT (
  handle   IN NUMBER,
  document IN sys.XMLType,
  result   IN OUT NOCOPY CLOB);

DBMS_METADATA.CONVERT (
  handle   IN NUMBER,
  document IN CLOB,
  result   IN OUT NOCOPY CLOB);
```

Parameters

Table 112-7 CONVERT Subprogram Parameters

Parameter	Description
handle	The handle returned from OPENW
document	The XML document containing object metadata of the type of the OPENW handle
result	The converted document

Return Values

Either XML or DDL, depending on the specified transforms.

Usage Notes

You can think of CONVERT as the second half of FETCH_xxx, either FETCH_DDL (for the function variants) or FETCH_CLOB (for the procedure variants). There are two differences:

- FETCH_xxx gets its XML document from the database, but CONVERT gets its XML document from the caller
- FETCH_DDL returns its results in a sys.ku$_ddls nested table, but CONVERT returns a sys.ku$_multi_ddls nested table

The transforms specified with ADD_TRANSFORM are applied in turn, and the result is returned to the caller. For the function variants, the DDL transform must be specified. If parse items were specified, they are returned in the parsedItems column. Parse items are ignored by the procedure variants.

The encoding of the XML document is embedded in its CLOB or XMLType representation. The version of the metadata is embedded in the XML. The generated DDL is valid for the database version specified in OPENW.

Exceptions

- INVALID_ARGVAL. A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- INCONSISTENT_OPERATION. No transform was specified. The DDL transform was not specified (function variants only).

- `INCOMPATIBLE_DOCUMENT`. The version of the XML document is not compatible with this version of the software.

112.6.4 FETCH_xxx Functions and Procedures

These functions and procedures return metadata for objects meeting the criteria established by `OPEN`, `SET_FILTER`, `SET_COUNT`, `ADD_TRANSFORM`, and so on.

See "Usage Notes" for the variants.

> **See Also:**
>
> For more information about related subprograms:
>
> - Subprograms for Retrieving Multiple Objects From the Database

Syntax

The `FETCH` functions are as follows:

```
DBMS_METADATA.FETCH_XML (
   handle  IN NUMBER)
RETURN sys.XMLType;

DBMS_METADATA.FETCH_DDL (
   handle  IN NUMBER)
RETURN sys.ku$_ddls;

DBMS_METADATA.FETCH_CLOB (
   handle       IN NUMBER,
   cache_lob    IN BOOLEAN DEFAULT TRUE,
   lob_duration IN PLS INTEGER DEFAULT DBMS_LOB.SESSION)
RETURN CLOB;
```

The `FETCH` procedures are as follows:

```
DBMS_METADATA.FETCH_CLOB (
   handle  IN NUMBER,
   doc     IN OUT NOCOPY CLOB);

DBMS_METADATA.FETCH_XML_CLOB (
   handle  IN NUMBER,
   doc     IN OUT NOCOPY CLOB,
   parsed_items OUT sys.ku$_parsed_items,
   object_type_path OUT VARCHAR2);
```

Parameters

Table 112-8 FETCH_xxx Function Parameters

Parameters	Description
`handle`	The handle returned from `OPEN`.
`cache_lob`	TRUE=read LOB into buffer cache

Table 112-8 (Cont.) FETCH_xxx Function Parameters

Parameters	Description
lob_duration	The duration for the temporary LOB created by FETCH_CLOB, either DBMS_LOB.SESSION (the default) or DBMS_LOB.CALL.
doc	The metadata for the objects, or NULL if all objects have been returned.
parsed_items	A nested table containing the items specified by SET_PARSE_ITEM. If SET_PARSE_ITEM was not called, a NULL is returned.
object_type_path	For heterogeneous object types, this is the full path name of the object type for the objects returned by the call to FETCH_XXX. If handle designates a homogeneous object type, a NULL is returned.

Return Values

The metadata for the objects or NULL if all objects have been returned.

Usage Notes

These functions and procedures return metadata for objects meeting the criteria established by the call to OPEN that returned the handle, and subsequent calls to SET_FILTER, SET_COUNT, ADD_TRANSFORM, and so on. Each call to FETCH_xxx returns the number of objects specified by SET_COUNT (or less, if fewer objects remain in the underlying cursor) until all objects have been returned. After the last object is returned, subsequent calls to FETCH_xxx return NULL and cause the stream created by OPEN to be transparently closed.

There are several different FETCH_xxx functions and procedures:

- The FETCH_XML function returns the XML metadata for an object as an XMLType. It assumes that if any transform has been specified, that transform will produce an XML document. In particular, it assumes that the DDL transform has not been specified.
- The FETCH_DDL function returns the DDL (to create the object) in a sys.ku$_ddls nested table. It assumes that the DDL transform has been specified. Each row of the sys.ku$_ddls nested table contains a single DDL statement in the ddlText column; if requested, parsed items for the DDL statement will be returned in the parsedItems column. Multiple DDL statements may be returned under the following circumstances:
  - When you call SET_COUNT to specify a count greater than 1
  - When an object is transformed into multiple DDL statements. For example, A TYPE object that has a DDL transform applied to it can be transformed into both CREATE TYPE and CREATE TYPE BODY statements. A TABLE object can be transformed into a CREATE TABLE, and one or more ALTER TABLE statements
- The FETCH_CLOB function simply returns the object, transformed or not, as a CLOB. By default, the CLOB is read into the buffer cache and has session duration, but these defaults can be overridden with the cache_lob and lob_duration parameters.

- The FETCH_CLOB procedure returns the objects by reference in an IN OUT NOCOPY parameter. This is faster than the function variant, which returns LOBs by value, a practice that involves an expensive LOB copy.
- The FETCH_XML_CLOB procedure returns the XML metadata for the objects as a CLOB in an IN OUT NOCOPY parameter. This helps to avoid LOB copies, which can consume a lot of resources. It also returns a nested table of parse items and the full path name of the object type of the returned objects.
- All LOBs returned by FETCH_xxx are temporary LOBs. You must free the LOB. If the LOB is supplied as an IN OUT NOCOPY parameter, you must also create the LOB.
- If SET_PARSE_ITEM was called, FETCH_DDL and FETCH_XML_CLOB return attributes of the object's metadata (or the DDL statement) in a sys.ku$_parsed_items nested table. For FETCH_XML_CLOB, the nested table is an OUT parameter. For FETCH_DDL, it is a column in the returned sys.ku$_ddls nested table. Each row of the nested table corresponds to an item specified by SET_PARSE_ITEM and contains the following columns:
  - item—the name of the attribute as specified in the name parameter to SET_PARSE_ITEM.
  - value—the attribute value, or NULL if the attribute is not present in the DDL statement.
  - object-row—a positive integer indicating the object to which the parse item applies. If multiple objects are returned by FETCH_xxx, (because SET_COUNT specified a count greater than 1) then object_row=1 for all items for the first object, 2 for the second, and so on.
- The rows of the sys.ku$_parsed_items nested table are ordered by ascending object_row, but otherwise the row order is undetermined. To find a particular parse item within an object row the caller must search the table for a match on item.
- In general there is no guarantee that a requested parse item will be returned. For example, the parse item may not apply to the object type or to the particular line of DDL, or the item's value may be NULL.
- If SET_PARSE_ITEM was not called, NULL is returned as the value of the parsed items nested table.
- It is expected that the same variant of FETCH_xxx will be called for all objects selected by OPEN. That is, programs will not intermix calls to FETCH_XML, FETCH_DDL, FETCH_CLOB, and so on using the same OPEN handle. The effect of calling different variants is undefined; it might do what you expect, but there are no guarantees.
- Every object fetched will be internally consistent with respect to on-going DDL (and the subsequent recursive DML) operations against the dictionary. In some cases, multiple queries may be issued, either because the object type is heterogeneous or for performance reasons (for example, one query for heap tables, one for index-organized tables). Consequently the FETCH_xxx calls may in fact be fetches from different underlying cursors (meaning that read consistency is not guaranteed).

Exceptions

Most exceptions raised during execution of the query are propagated to the caller. Also, the following exceptions may be raised:

- INVALID_ARGVAL. A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- INCONSISTENT_OPERATION. Either FETCH_XML was called when the DDL transform had been specified, or FETCH_DDL was called when the DDL transform had *not* been specified.

112.6.5 GET_xxx Functions

`GET_xxx` functions let you fetch metadata for objects with a single call.

These `GET_xxx` functions are:

- `GET_XML`
- `GET_DDL`
- `GET_SXML`
- `GET_DEPENDENT_XML`
- `GET_DEPENDENT_DDL`
- `GET_GRANTED_XML`
- `GET_GRANTED_DDL`

> **See Also:**
>
> For more information about related subprograms:
>
> – Subprograms for Retrieving Multiple Objects From the Database

Syntax

```
DBMS_METADATA.GET_XML (
object_type     IN VARCHAR2,
name            IN VARCHAR2,
schema          IN VARCHAR2 DEFAULT NULL,
version         IN VARCHAR2 DEFAULT 'COMPATIBLE',
model           IN VARCHAR2 DEFAULT 'ORACLE',
transform       IN VARCHAR2 DEFAULT NULL)
RETURN CLOB;

DBMS_METADATA.GET_DDL (
object_type     IN VARCHAR2,
name            IN VARCHAR2,
schema          IN VARCHAR2 DEFAULT NULL,
version         IN VARCHAR2 DEFAULT 'COMPATIBLE',
model           IN VARCHAR2 DEFAULT 'ORACLE',
transform       IN VARCHAR2 DEFAULT 'DDL')
RETURN CLOB;

DBMS_METADATA.GET_SXML (
object_type     IN VARCHAR2,
name            IN VARCHAR2 DEFAULT NULL,
schema          IN VARCHAR2 DEFAULT NULL,
version         IN VARCHAR2 DEFAULT 'COMPATIBLE',
model           IN VARCHAR2 DEFAULT 'ORACLE',
transform       IN VARCHAR2 DEFAULT 'SXML')
RETURN CLOB;

DBMS_METADATA.GET_DEPENDENT_XML (
object_type        IN VARCHAR2,
base_object_name   IN VARCHAR2,
base_object_schema IN VARCHAR2 DEFAULT NULL,
```

```
version            IN VARCHAR2 DEFAULT 'COMPATIBLE',
model              IN VARCHAR2 DEFAULT 'ORACLE',
transform          IN VARCHAR2 DEFAULT NULL,
object_count       IN NUMBER   DEFAULT 10000)
RETURN CLOB;

DBMS_METADATA.GET_DEPENDENT_DDL (
object_type         IN VARCHAR2,
base_object_name    IN VARCHAR2,
base_object_schema  IN VARCHAR2 DEFAULT NULL,
version             IN VARCHAR2 DEFAULT 'COMPATIBLE',
model               IN VARCHAR2 DEFAULT 'ORACLE',
transform           IN VARCHAR2 DEFAULT 'DDL',
object_count        IN NUMBER   DEFAULT 10000)
RETURN CLOB;

DBMS_METADATA.GET_GRANTED_XML (
object_type     IN VARCHAR2,
grantee         IN VARCHAR2 DEFAULT NULL,
version         IN VARCHAR2 DEFAULT 'COMPATIBLE',
model           IN VARCHAR2 DEFAULT 'ORACLE',
transform       IN VARCHAR2 DEFAULT NULL,
object_count    IN NUMBER   DEFAULT 10000)
RETURN CLOB;

DBMS_METADATA.GET_GRANTED_DDL (
object_type     IN VARCHAR2,
grantee         IN VARCHAR2 DEFAULT NULL,
version         IN VARCHAR2 DEFAULT 'COMPATIBLE',
model           IN VARCHAR2 DEFAULT 'ORACLE',
transform       IN VARCHAR2 DEFAULT 'DDL',
object_count    IN NUMBER   DEFAULT 10000)
RETURN CLOB;
```

Parameters

Table 112-9 GET_xxx Function Parameters

Parameter	Description
object_type	The type of object to be retrieved. This parameter takes the same values as the OPEN object_type parameter, except that it cannot be a heterogeneous object type. The attributes of the object type must be appropriate to the function. That is, for GET_xxx it must be a named object.
name	The object name. It is used internally in a NAME filter. (If the name is longer than 30 characters, it will be used in a LONGNAME filter.) If this parameter is NULL, then no NAME or LONGNAME filter is specified. See Table 112-18 for a list of filters.
schema	The object schema. It is used internally in a SCHEMA filter. The default is the current user.
version	The version of metadata to be extracted. This parameter takes the same values as the OPEN version parameter.
model	The object model to use. This parameter takes the same values as the OPEN model parameter.

Table 112-9 (Cont.) GET_xxx Function Parameters

Parameter	Description
transform	The name of a transformation on the output. This parameter takes the same values as the ADD_TRANSFORM name parameter. For GET_XML this must not be DDL.
base_object_name	The base object name. It is used internally in a BASE_OBJECT_NAME filter.
base_object_schema	The base object schema. It is used internally in a BASE_OBJECT_SCHEMA filter. The default is the current user.
grantee	The grantee. It is used internally in a GRANTEE filter. The default is the current user.
object_count	The maximum number of objects to return. See SET_COUNT Procedure .

Return Values

The metadata for the specified object as XML or DDL.

Usage Notes

- These functions allow you to fetch metadata for objects with a single call. They encapsulate calls to OPEN, SET_FILTER, and so on. The function you use depends on the characteristics of the object type and on whether you want XML, SXML, or DDL.
  - GET_xxx is used to fetch named objects, especially schema objects (tables, views).
  - GET_DEPENDENT_xxx is used to fetch dependent objects (audits, object grants).
  - GET_GRANTED_xxx is used to fetch granted objects (system grants, role grants).
- For some object types you can use more than one function. For example, you can use GET_xxx to fetch an index by name, or GET_DEPENDENT_xxx to fetch the same index by specifying the table on which it is defined.
- GET_xxx only returns a single named object.
- For GET_DEPENDENT_xxx and GET_GRANTED_xxx, an arbitrary number of dependent or granted objects can match the input criteria. You can specify an object count when fetching these objects. (The default count of 10000 should be adequate in most cases.)
- If the DDL transform is specified, session-level transform parameters are inherited.
- If you invoke these functions from SQL*Plus, you should set the PAGESIZE to 0 and set LONG to some large number to get complete, uninterrupted output.

Exceptions

- INVALID_ARGVAL. A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- OBJECT_NOT_FOUND. The specified object was not found in the database.

Examples

Example: Fetch the XML Representation of SCOTT.EMP

To generate complete, uninterrupted output, set the `PAGESIZE` to 0 and set `LONG` to some large number, as shown, before executing your query.

```
SET LONG 2000000
SET PAGESIZE 0
SELECT DBMS_METADATA.GET_XML('TABLE','EMP','SCOTT')
FROM DUAL;
```

Example: Fetch the DDL for all Complete Tables in the Current Schema, Filter Out Nested Tables and Overflow Segments

This example fetches the DDL for all "complete" tables in the current schema, filtering out nested tables and overflow segments. The example uses `SET_TRANSFORM_PARAM` (with the handle value = `DBMS_METADATA.SESSION_TRANSFORM` meaning "for the current session") to specify that storage clauses are not to be returned in the SQL DDL. Afterwards, the example resets the session-level parameters to their defaults.

To generate complete, uninterrupted output, set the `PAGESIZE` to 0 and set `LONG` to some large number, as shown, before executing your query.

```
SET LONG 2000000
SET PAGESIZE 0
EXECUTE
DBMS_METADATA.SET_TRANSFORM_PARAM(DBMS_METADATA.SESSION_TRANSFORM,'STORAGE',false);
SELECT DBMS_METADATA.GET_DDL('TABLE',u.table_name)
     FROM USER_ALL_TABLES u
     WHERE u.nested='NO'
     AND (u.iot_type is null or u.iot_type='IOT');
EXECUTE DBMS_METADATA.SET_TRANSFORM_PARAM(DBMS_METADATA.SESSION_TRANSFORM,'DEFAULT');
```

Example: Fetch the DDL For All Object Grants On HR.EMPLOYEES

```
SELECT DBMS_METADATA.GET_DEPENDENT_DDL('OBJECT_GRANT',
    'EMPLOYEES','HR') FROM DUAL;
```

Example: Fetch the DDL For All System Grants Granted To SCOTT

```
SELECT DBMS_METADATA.GET_GRANTED_DDL('SYSTEM_GRANT','SCOTT')
    FROM DUAL;
```

112.6.6 GET_QUERY Function

This function returns the text of the queries that are used by `FETCH_xxx`. This function assists in debugging.

> **See Also:**
>
> For more information about related subprograms:
>
> - Subprograms for Retrieving Multiple Objects From the Database

Syntax

```
DBMS_METADATA.GET_QUERY (
   handle  IN NUMBER)
 RETURN VARCHAR2;
```

Parameters

Table 112-10 GET_QUERY Function Parameters

Parameter	Description
handle	The handle returned from OPEN. It cannot be the handle for a heterogeneous object type.

Return Values

The text of the queries that will be used by FETCH_xxx.

Exceptions

- INVALID_ARGVAL. A NULL or invalid value was supplied for the handle parameter.

112.6.7 OPEN Function

The DBMS_METADATA.OPEN function specifies the type of object to be retrieved, the version of its metadata, and the object model.

lThe return value is an opaque context handle for the set of objects to be used in subsequent calls.

> **See Also:**
>
> For more information about related subprograms:
>
> - Subprograms for Retrieving Multiple Objects From the Database

Syntax

```
DBMS_METADATA.OPEN (
   object_type  IN VARCHAR2,
   version      IN VARCHAR2 DEFAULT 'COMPATIBLE',
   model        IN VARCHAR2 DEFAULT 'ORACLE',
   network_link IN VARCHAR2 DEFAULT NULL)
 RETURN NUMBER;
```

Parameters

Table 112-11 Open Function Parameters

Parameter	Description
object_type	The type of object to be retrieved. Table 112-12 lists the valid type names and their meanings. These object types will be supported for the ORACLE model of metadata (see model in this table). The Attributes column in Table 112-12 specifies some object type attributes: • Schema objects, such as tables, belong to schemas. • Named objects have unique names (if they are schema objects, the name is unique to the schema). • Dependent objects, such as indexes, are defined with reference to a base schema object. • Granted objects are granted or assigned to a user or role and therefore have a named grantee. • Heterogeneous object types denote a collection of related objects of different types. See Table 112-13 for a listing of object types returned for the heterogeneous object type. These attributes are relevant when choosing object selection criteria. See "SET_FILTER Procedure" for more information.
version	The version of metadata to be extracted. Database objects or attributes that are incompatible with the version will not be extracted. Legal values for this parameter are as follows: COMPATIBLE (default)—the version of the metadata corresponds to the database compatibility level. LATEST—the version of the metadata corresponds to the database version. A specific database version. The value cannot be lower than 9.2.0.
model	Specifies which view to use, because the API can support multiple views on the metadata. Only the ORACLE model is supported.
network_link	The name of a database link to the database whose metadata is to be retrieved. If NULL (the default), metadata is retrieved from the database on which the caller is running

Table 112-12 provides the name, meaning, attributes, and notes for the DBMS_METADATA package object types. In the attributes column, S represents a schema object, N represents a named object, D represents a dependent object, G represents a granted object, and H represents a heterogeneous object.

Table 112-12 DBMS_METADATA: Object Types

Type Name	Meaning	Attributes	Notes
AQ_QUEUE	queues	SND	Dependent on table
AQ_QUEUE_TABLE	additional metadata for queue tables	ND	Dependent on table
AQ_TRANSFORM	transforms	SN	None
ASSOCIATION	associate statistics	D	None

Table 112-12 (Cont.) DBMS_METADATA: Object Types

Type Name	Meaning	Attributes	Notes
AUDIT	audits of SQL statements	DG	Modeled as dependent, granted object. The base object name is the statement audit option name (for example, ALTER SYSTEM). There is no base object schema. The grantee is the user or proxy whose statements are audited.
AUDIT_OBJ	audits of schema objects	D	None
CLUSTER	clusters	SN	None
COMMENT	comments	D	None
CONSTRAINT	constraints	SND	Does not include: • primary key constraint for IOT • column NOT NULL constraints • certain REF SCOPE and WITH ROWID constraints for tables with REF columns
CONTEXT	application contexts	N	None
DATABASE_EXPORT	all metadata objects in a database	H	Corresponds to a full database export
DB_LINK	database links	SN	Modeled as schema objects because they have owners. For public links, the owner is PUBLIC. For private links, the creator is the owner.
DEFAULT_ROLE	default roles	G	Granted to a user by ALTER USER
DIMENSION	dimensions	SN	None
DIRECTORY	directories	N	None
FGA_POLICY	fine-grained audit policies	D	Not modeled as named object because policy names are not unique.
FUNCTION	stored functions	SN	None
INDEX_STATISTICS	precomputed statistics on indexes	D	The base object is the index's table.
INDEX	indexes	SND	None
INDEXTYPE	indextypes	SN	None
JAVA_SOURCE	Java sources	SN	None
JOB	jobs	S	None
LIBRARY	external procedure libraries	SN	None
MATERIALIZED_VIEW	materialized views	SN	None
MATERIALIZED_VIEW_LOG	materialized view logs	D	None
OBJECT_GRANT	object grants	DG	None
OPERATOR	operators	SN	None
PACKAGE	stored packages	SN	By default, both package specification and package body are retrieved. See "SET_FILTER Procedure".

Table 112-12 (Cont.) DBMS_METADATA: Object Types

Type Name	Meaning	Attributes	Notes
PACKAGE_SPEC	package specifications	SN	None
PACKAGE_BODY	package bodies	SN	None
PROCEDURE	stored procedures	SN	None
PROFILE	profiles	N	None
PROXY	proxy authentications	G	Granted to a user by ALTER USER
REF_CONSTRAINT	referential constraint	SND	None
REFRESH_GROUP	refresh groups	SN	None
RESOURCE_COST	resource cost info		None
RLS_CONTEXT	driving contexts for enforcement of fine-grained access-control policies	D	Corresponds to the DBMS_RLS.ADD_POLICY_CONTENT procedure
RLS_GROUP	fine-grained access-control policy groups	D	Corresponds to the DBMS_RLS.CREATE_GROUP procedure
RLS_POLICY	fine-grained access-control policies	D	Corresponds to DBMS_RLS.ADD_GROUPED_POLICY. Not modeled as named objects because policy names are not unique.
RMGR_CONSUMER_GROUP	resource consumer groups	SN	Data Pump does not use these object types. Instead, it exports resource manager objects as procedural objects.
RMGR_INTITIAL_CONSUMER_GROUP	assign initial consumer groups to users	G	None
RMGR_PLAN	resource plans	SN	None
RMGR_PLAN_DIRECTIVE	resource plan directives	D	Dependent on resource plan
ROLE	roles	N	None
ROLE_GRANT	role grants	G	None
ROLLBACK_SEGMENT	rollback segments	N	None
SCHEMA_EXPORT	all metadata objects in a schema	H	Corresponds to user-mode export.
SEQUENCE	sequences	SN	None
SYNONYM	synonyms	See notes	Private synonyms are schema objects. Public synonyms are not, but for the purposes of this API, their schema name is PUBLIC. The name of a synonym is considered to be the synonym itself. For example, in CREATE PUBLIC SYNONYM FOO FOR BAR, the resultant object is considered to have name FOO and schema PUBLIC.
SYSTEM_GRANT	system privilege grants	G	None
TABLE	tables	SN	None

Table 112-12 (Cont.) DBMS_METADATA: Object Types

Type Name	Meaning	Attributes	Notes
TABLE_DATA	metadata describing row data for a table, nested table, or partition	SND	For partitions, the object name is the partition name. For nested tables, the object name is the storage table name. The base object is the top-level table to which the table data belongs. For nested tables and partitioning, this is the top-level table (*not* the parent table or partition). For nonpartitioned tables and non-nested tables this is the table itself.
TABLE_EXPORT	metadata for a table and its associated objects	H	Corresponds to table-mode export
TABLE_STATISTICS	precomputed statistics on tables	D	None
TABLESPACE	tablespaces	N	None
TABLESPACE_QUOTA	tablespace quotas	G	Granted with ALTER USER
TRANSPORTABLE_EXPORT	metadata for objects in a transportable tablespace set	H	Corresponds to transportable tablespace export
TRIGGER	triggers	SND	None
TRUSTED_DB_LINK	trusted links	N	None
TYPE	user-defined types	SN	By default, both type and type body are retrieved. See "SET_FILTER Procedure".
TYPE_SPEC	type specifications	SN	None
TYPE_BODY	type bodies	SN	None
USER	users	N	None
VIEW	views	SN	None
XMLSCHEMA	XML schema	SN	The object's name is its URL (which may be longer than 30 characters). Its schema is the user who registered it.
XS_USER	Real Application Security (RAS) user	N	Corresponds to RAS users
XS_ROLE	Real Application Security (RAS) role	N	Corresponds to RAS roles
XS_ROLESET	Real Application Security (RAS) rolesets	N	Corresponds to RAS rolesets
XS_ROLE_GRANT	Real Application Security (RAS) role grants	N	Corresponds to RAS role grants
XS_SECURITY_CLASS	Real Application Security (RAS) security class	SN	Corresponds to RAS security classes
XS_DATA_SECURITY	Real Application Security (RAS) data security policy	SN	Corresponds to RAS data security policies
XS_ACL	Real Application Security (RAS) ACL	SN	Corresponds to RAS access control lists (ACLs) and associated access control entries (ACEs)

Table 112-12 (Cont.) DBMS_METADATA: Object Types

Type Name	Meaning	Attributes	Notes
XS_ACL_PARAM	Real Application Security (RAS) ACL parameter	N	Corresponds to RAS access control lists (ACL) parameters
XS_NAMESPACE	Real Application Security (RAS) namespace	N	Corresponds to RAS namespaces.

Table 112-13 lists the types of objects returned for the major heterogeneous object types. For SCHEMA_EXPORT, certain object types are only returned if the INCLUDE_USER filter is specified at TRUE. In the table, such object types are marked INCLUDE_USER.

Table 112-13 Object Types Returned for the Heterogeneous Object Type

TYPE_BODY	Yes	Yes	No	Yes, if the types are used by tables in the transportable set
USER	Yes	INCLUDE_USER	No	No
VIEW	Yes	Yes	No	No
XMLSCHEMA	Yes	Yes	No	No

Return Values

An opaque handle to the class of objects. This handle is used as input to `SET_FILTER`, `SET_COUNT`, `ADD_TRANSFORM`, `GET_QUERY`, `SET_PARSE_ITEM`, `FETCH_xxx`, and `CLOSE`.

Exceptions

- `INVALID_ARGVAL`. A `NULL` or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- `INVALID_OBJECT_PARAM`. The `version` or `model` parameter was not valid for the `object_type`.

112.6.8 OPENW Function

This function specifies the type of object to be submitted and the object model. The return value is an opaque context handle.

> **See Also:**
>
> For more information about related subprograms:
>
> - Subprograms for Submitting XML to the Database

Syntax

```
DBMS_METADATA.OPENW
  (object_type  IN VARCHAR2,
  version       IN VARCHAR2 DEFAULT 'COMPATIBLE',
  model         IN VARCHAR2 DEFAULT 'ORACLE')
 RETURN NUMBER;
```

Parameters

Table 112-14 OPENW Function Parameters

Parameter	Description
`object_type`	The type of object to be submitted. Valid types names and their meanings are listed in Table 112-12. The type cannot be a heterogeneous object type.
`version`	The version of DDL to be generated by the `CONVERT` function. DDL clauses that are incompatible with the version will not be generated. The legal values for this parameter are as follows: • `COMPATIBLE` - This is the default. The version of the DDL corresponds to the database compatibility level. Database compatibility must be set to 9.2.0 or higher. • `LATEST` - The version of the DDL corresponds to the database version. • A specific database version. The value cannot be lower than 9.2.0.
`model`	Specifies which view to use. Only the Oracle proprietary (ORACLE) view is supported by `DBMS_METADATA`.

Return Values

An opaque handle to write context. This handle is used as input to the `ADD_TRANSFORM`, `CONVERT`, `PUT`, and `CLOSE` procedures.

Exceptions

- `INVALID_ARGVAL`. A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- `INVALID_OBJECT_PARAM`. The `model` parameter was not valid for the `object_type`.

112.6.9 PUT Function

This function submits an XML document containing object metadata to the database to create the object.

> **See Also:**
>
> For more information about related subprograms:
>
> - Subprograms for Submitting XML to the Database

Syntax

```
DBMS_METADATA.PUT (
   handle     IN             NUMBER,
   document   IN             sys.XMLType,
   flags      IN             NUMBER,
   results    IN OUT NOCOPY  sys.ku$_SubmitResults)
  RETURN BOOLEAN;

DBMS_METADATA.PUT (
   handle     IN             NUMBER,
   document   IN             CLOB,
   flags      IN             NUMBER,
   results    IN OUT NOCOPY  sys.ku$_SubmitResults)
 RETURN BOOLEAN;
```

Parameters

Table 112-15 PUT Function Parameters

Parameter	Description
`handle`	The handle returned from `OPENW`.
`document`	The XML document containing object metadata for the type of the `OPENW` handle.
`flags`	Reserved for future use
`results`	Detailed results of the operation.

Return Values

TRUE if all SQL operations succeeded; FALSE if there were any errors.

Usage Notes

The PUT function converts the XML document to DDL just as CONVERT does (applying the specified transforms in turn) and then submits each resultant DDL statement to the database. As with CONVERT, the DDL transform must be specified. The DDL statements and associated parse items are returned in the sys.ku$_SubmitResults nested table. With each DDL statement is a nested table of error lines containing any errors or exceptions raised by the statement.

The encoding of the XML document is embedded in its CLOB or XMLType representation. The version of the metadata is embedded in the XML. The generated DDL is valid for the database version specified in OPENW.

Exceptions

- INVALID_ARGVAL. A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- INCONSISTENT_OPERATION. The DDL transform was not specified.
- INCOMPATIBLE_DOCUMENT. The version of the XML document is not compatible with this version of the software.

112.6.10 SET_COUNT Procedure

This procedure specifies the maximum number of objects to be retrieved in a single FETCH_xxx call.

By default, each call to FETCH_xxx returns one object. You can use the SET_COUNT procedure to override this default. If FETCH_xxx is called from a client, specifying a count value greater than 1 can result in fewer server round trips and, therefore, improved performance.

For heterogeneous object types, a single FETCH_xxx operation only returns objects of a single object type.

> **See Also:**
>
> For more information about related subprograms:
>
> - Subprograms for Retrieving Multiple Objects From the Database

Syntax

```
DBMS_METADATA.SET_COUNT (
   handle           IN NUMBER,
   value            IN NUMBER,
   object_type_path IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 112-16 SET_COUNT Procedure Parameters

Parameter	Description
handle	The handle returned from OPEN.
value	The maximum number of objects to retrieve.
object_type_path	A path name designating the object types to which the count value applies. By default, the count value applies to the object type of the OPEN handle. When the OPEN handle designates a heterogeneous object type, behavior can be either of the following: • If object_type_path is omitted, then the count applies to all object types within the heterogeneous collection. • If object_type_path is specified, then the count only applies to the specific node (or set of nodes) within the tree of object types forming the heterogeneous collection.

Exceptions

- INVALID_ARGVAL. A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- INVALID_OPERATION. SET_COUNT was called after the first call to FETCH_xxx for the OPEN context. After the first call to FETCH_xxx is made, no further calls to SET_COUNT for the current OPEN context are permitted.
- INCONSISTENT_ARGS. object_type parameter is not consistent with handle.

112.6.11 SET_FILTER Procedure

This procedure specifies restrictions on the objects to be retrieved, for example, the object name or schema.

> **See Also:**
>
> For more information about related subprograms:
>
> - Subprograms for Retrieving Multiple Objects From the Database

Syntax

```
DBMS_METADATA.SET_FILTER (
   handle           IN NUMBER,
   name             IN VARCHAR2,
   value            IN VARCHAR2,
   object_type_path IN VARCHAR2 DEFAULT NULL);

DBMS_METADATA.SET_FILTER (
   handle            IN NUMBER,
   name              IN VARCHAR2,
   value             IN BOOLEAN DEFAULT TRUE,
   object_type_path  IN VARCHAR2 DEFAULT NULL);
```

```
DBMS_METADATA.SET_FILTER (
   handle            IN NUMBER,
   name              IN VARCHAR2,
   value             IN NUMBER,
   object_type_path  IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 112-17 SET_FILTER Procedure Parameters

Parameter	Description
handle	The handle returned from OPEN.
name	The name of the filter. For each filter, Table 112-18 lists the object_type it applies to, its name, its datatype (text or Boolean), and its meaning or effect (including its default value, if any). The Datatype column of Table 112-18 also indicates whether a text filter is an expression filter. An expression filter is the right-hand side of a SQL comparison (that is, a SQL comparison operator (=, !=, and so on.)) and the value compared against. The value must contain parentheses and quotation marks where appropriate. Note that in PL/SQL and SQL*Plus, two single quotes (*not* a double quote) are needed to represent an apostrophe. For example, an example of a NAME_EXPR filter in PL/SQL is as follows: 'IN (''DEPT'',''EMP'')' The filter value is combined with a particular object attribute to produce a WHERE condition in the query that fetches the objects. In the preceding example, the filter is combined with the attribute corresponding to an object name; objects named 'DEPT' and 'EMP' are selected.
value	The value of the filter. Text, Boolean, and Numeric filters are supported.
object_type_path	A path name designating the object types to which the filter applies. By default, the filter applies to the object type of the OPEN handle. When the OPEN handle designates a heterogeneous object type, you can use this parameter to specify a filter for a specific node or set of nodes within the tree of object types that form the heterogeneous collection. See Table 112-19 for a listing of some of the values for this parameter.

Table 112-18 describes the object type, name, datatype, and meaning of the filters available with the SET_FILTER procedure.

Table 112-18 SET_FILTER: Filters

Object Type	Name	Datatype	Meaning
Named objects	NAME	Text	Objects with this exact name are selected.
Named objects	NAME_EXPR	Text expression	The filter value is combined with the object attribute corresponding to the object name to produce a WHERE condition in the query that fetches the objects. By default, all named objects of object_type are selected.

Table 112-18 (Cont.) SET_FILTER: Filters

Object Type	Name	Datatype	Meaning
Named objects	EXCLUDE_NAME_EXPR	Text expression	The filter value is combined with the attribute corresponding to the object name to specify objects that are to be excluded from the set of objects fetched. By default, all named objects of the object type are selected.
TABLE_EXPORT	EXCLUDE_TABLES	Boolean	If TRUE, all paths associated with tables are excluded from the set of objects fetched. If FALSE (the default), all paths associated with tables are fetched.
Schema objects	SCHEMA	Text	Objects in this schema are selected. If the object type is SYNONYM, then specify PUBLIC to select public synonyms.
Schema objects	SCHEMA_EXPR	Text expression	The filter value is combined with the attribute corresponding to the object's schema. The default is determined as follows: - if BASE_OBJECT_SCHEMA is specified, then objects in that schema are selected; - otherwise, objects in the current schema are selected.
PACKAGE, TYPE	SPECIFICATION	Boolean	If TRUE, retrieve the package or type specification. Defaults to TRUE.
PACKAGE, TYPE	BODY	Boolean	If TRUE, retrieve the package or type body. Defaults to TRUE.
TABLE, CLUSTER, INDEX, TABLE_DATA, TABLE_EXPORT, TRANSPORTABLE_EXPORT	TABLESPACE	Text	Objects in this tablespace (or having a partition in this tablespace) are selected.
TABLE, CLUSTER, INDEX, TABLE_DATA, TABLE_EXPORT, TRANSPORTABLE_EXPORT	TABLESPACE_EXPR	Text expression	The filter value is combined with the attribute corresponding to the object's tablespace (or in the case of a partitioned table or index, the partition's tablespaces). By default, objects in all tablespaces are selected.
TABLE, objects dependent on tables	PRIMARY	Boolean	If TRUE, retrieve primary tables (that is, tables for which the secondary object bit in obj$ is clear. Defaults to TRUE.
TABLE, objects dependent on tables	SECONDARY	Boolean	If TRUE, retrieve secondary tables (that is, tables for which the secondary object bit in obj$ is set). Defaults to TRUE.

Table 112-18 (Cont.) SET_FILTER: Filters

Object Type	Name	Datatype	Meaning
Dependent Objects	BASE_OBJECT_NAME	Text	Objects are selected that are defined or granted on objects with this name. Specify SCHEMA for triggers on schemas. Specify DATABASE for database triggers. Column-level comments cannot be selected by column name; the base object name must be the name of the table, view, or materialized view containing the column.
Dependent Objects	BASE_OBJECT_SCHEMA	Text	Objects are selected that are defined or granted on objects in this schema. If BASE_OBJECT_NAME is specified with a value other than SCHEMA or DATABASE, this defaults to the current schema.
Dependent Objects	BASE_OBJECT_NAME_EXPR	Text expression	The filter value is combined with the attribute corresponding to the name of the base object. Not valid for schema and database triggers.
Dependent Objects	EXCLUDE_BASE_OBJECT_NAME_EXPR	Text expression	The filter value is combined with the attribute corresponding to the name of the base object to specify objects that are to be excluded from the set of objects fetched. Not valid for schema and database triggers.
Dependent Objects	BASE_OBJECT_SCHEMA_EXPR	Text expression	The filter value is combined with the attribute corresponding to the schema of the base object.
Dependent Objects	BASE_OBJECT_TYPE	Text	The object type of the base object.
Dependent Objects	BASE_OBJECT_TYPE_EXPR	Text expression	The filter value is combined with the attribute corresponding to the object type of the base object. By default no filtering is done on object type.
Dependent Objects	BASE_OBJECT_TABLESPACE	Text	The tablespace of the base object.
Dependent Objects	BASE_OBJECT_TABLESPACE_EXPR	Text expression	The filter value is combined with the attribute corresponding to the tablespaces of the base object. By default, no filtering is done on the tablespace.
INDEX, TRIGGER	SYSTEM_GENERATED	Boolean	If TRUE, select indexes or triggers even if they are system-generated. If FALSE, omit system-generated indexes or triggers. Defaults to TRUE.
Granted Objects	GRANTEE	Text	Objects are selected that are granted to this user or role. Specify PUBLIC for grants to PUBLIC.
Granted Objects	PRIVNAME	Text	The name of the privilege or role to be granted. For TABLESPACE_QUOTA, only UNLIMITED can be specified.
Granted Objects	GRANTEE_EXPR	Text expression	The filter value is combined with the attribute corresponding to the grantee name.

Table 112-18 (Cont.) SET_FILTER: Filters

Object Type	Name	Datatype	Meaning
Granted Objects	EXCLUDE_GRANTEE_EXPR	Text expression	The filter value is combined with the attribute corresponding to the grantee name to specify objects that are to be excluded from the set of objects fetched.
OBJECT_GRANT	GRANTOR	Text	Object grants are selected that are granted by this user.
SYNONYM, JAVA_SOURCE, XMLSCHEMA	LONGNAME	Text	A name longer than 30 characters. Objects with this exact name are selected. If the object name is 30 characters or less, the NAME filter must be used.
SYNONYM, JAVA_SOURCE, XMLSCHEMA	LONGNAME_EXPR	Text	The filter value is combined with the attribute corresponding to the object's long name. By default, no filtering is done on the long name of an object.
All objects	CUSTOM_FILTER	Text	The text of a WHERE condition. The condition is appended to the query that fetches the objects. By default, no custom filter is used. The other filters are intended to meet the needs of the majority of users. Use CUSTOM_FILTER when no defined filters exists for your purpose. Of necessity such a filter depends on the detailed structure of the UDTs and views used in the query. Because filters may change from version to version, upward compatibility is not guaranteed.
All objects	EDITION	Text	The edition filter is accepted for any object type, but affects only objects that support editions. The filter is only accepted for local objects (that is, the network_link parameter is not specified in the OPEN call). The edition name must be a valid edition name. If an edition is not specified, the edition of the active session is used.
SCHEMA_EXPORT	SCHEMA	Text	The schema whose objects are selected.
SCHEMA_EXPORT	SCHEMA_EXPR	Text expression	The filter value is either: combined with the attribute corresponding to a schema name to produce a WHERE condition in the query that fetches schema objects, combined with the attribute corresponding to a base schema name to produce a WHERE condition in the query that fetches dependent objects. By default the current user's objects are selected.

Table 112-18 (Cont.) SET_FILTER: Filters

Object Type	Name	Datatype	Meaning
SCHEMA_EXPORT	INCLUDE_USER	Boolean	If TRUE, retrieve objects containing privileged information about the user. For example, USER, PASSWORD_HISTORY, TABLESPACE_QUOTA. Defaults to FALSE.
TABLE_EXPORT	SCHEMA	Text	Objects (tables and their dependent objects) in this schema are selected.
TABLE_EXPORT	SCHEMA_EXPR	Text expression	The filter value is either: combined with the attribute corresponding to a schema name to produce a WHERE condition in the query that fetches the tables, combined with the attribute corresponding to a base schema name to produce a WHERE condition in the query that fetches the tables' dependent objects. By default the current user's objects are selected.
TABLE_EXPORT	NAME	Text	The table with this exact name is selected along with its dependent objects.
TABLE_EXPORT	NAME_EXPR	Text expression	The filter value is combined with the attribute corresponding to a table name in the queries that fetch tables and their dependent objects. By default all tables in the selected schemas are selected, along with their dependent objects.
Heterogeneous objects	BEGIN_WITH	Text	The fully qualified path name of the first object type in the heterogeneous collection to be retrieved. Objects normally fetched prior to this object type will not be retrieved.
Heterogeneous objects	BEGIN_AFTER	Text	The fully qualified path name of an object type after which the heterogeneous retrieval should begin. Objects of this type will not be retrieved, nor will objects normally fetched prior to this object type.
Heterogeneous objects	END_BEFORE	Text	The fully qualified path name of an object type where the heterogeneous retrieval should end. Objects of this type will not be retrieved, nor will objects normally fetched after this object type.
Heterogeneous objects	END_WITH	Text	The fully qualified path name of the last object type in the heterogeneous collection to be retrieved. Objects normally fetched after this object type will not be retrieved.

Table 112-18 (Cont.) SET_FILTER: Filters

Object Type	Name	Datatype	Meaning
Heterogeneous objects	INCLUDE_PATH_EXPR, EXCLUDE_PATH_EXPR	Text expression	For these two filters, the filter value is combined with the attribute corresponding to an object type path name to produce a WHERE condition in the query that fetches the object types belonging to the heterogeneous collection. Objects of types satisfying this condition are included (INCLUDE_PATH_EXPR) or excluded (EXCLUDE_PATH_EXPR) from the set of object types fetched. Path names in the filter value do not have to be fully qualified. See Table 112-19 for valid path names that can be used with these filters. BEGIN_WITH, BEGIN_AFTER, END_BEFORE, END_WITH, INCLUDE_PATH_EXPR, and EXCLUDE_PATH_EXPR all restrict the set of object types in the heterogeneous collection. By default, objects of all object types in the heterogeneous collection are retrieved.

Usage Notes

- Each call to SET_FILTER causes a WHERE condition to be added to the underlying query that fetches the set of objects. The WHERE conditions are concatenated with the AND keyword so that you can use multiple SET_FILTER calls to refine the set of objects to be returned. For example to specify that you want the object named EMP in schema SCOTT, do the following:

```
SET_FILTER(handle,'SCHEMA','SCOTT');
SET_FILTER(handle,'NAME','EMP');
```

- You can use the same text expression filter multiple times with different values. All the filter conditions will be applied to the query. For example, to get objects with names between Felix and Oscar, do the following:

```
SET_FILTER(handle,'NAME_EXPR','>=''FELIX''');
SET_FILTER(handle,'NAME_EXPR','<=''OSCAR''');
```

- With SET_FILTER, you can specify the schema of objects to be retrieved, but security considerations may override this specification. If the caller is SYS or has the SELECT_CATALOG_ROLE role, then any object can be retrieved; otherwise, only the following can be retrieved:
  - Schema objects owned by the current user
  - Public synonyms
  - System privileges granted to the current user or to PUBLIC
  - Grants on objects for which the current user is owner, grantor, or grantee (either explicitly or as PUBLIC).
  - SCHEMA_EXPORT where the name is the current user
  - TABLE_EXPORT where SCHEMA is the current user

If you request objects that you are not privileged to retrieve, no exception is raised; the object is not retrieved, as if it did not exist.

In stored procedures, functions, and definers-rights packages, roles (such as SELECT_CATALOG_ROLE) are disabled. Therefore, such a PL/SQL program can only fetch metadata for objects in its own schema. If you want to write a PL/SQL program that fetches metadata for objects in a different schema (based on the invoker's possession of SELECT_CATALOG_ROLE), you must make the program invokers-rights.

- For heterogeneous object types, the BEGIN_WITH and BEGIN_AFTER filters allow restart on an object type boundary. Appropriate filter values are returned by the FETCH_XML_CLOB procedure.

  Filters on heterogeneous objects provide default values for filters on object types within the collection. You can override this default for a particular object type by specifying the appropriate filter for the specific object type path. For example, for SCHEMA_EXPORT the NAME filter specifies the schema to be fetched including all the tables in the schema, but you can further restrict this set of tables by supplying a NAME_EXPR filter explicitly for the TABLE object type path. Table 112-19 lists valid object type path names for the major heterogeneous object types along with an explanation of the scope of each path name. (The same information is available in the following catalog views: DATABASE_EXPORT_OBJECTS, SCHEMA_EXPORT_OBJECTS, and TABLE_EXPORT_OBJECTS.) See Table 112-18 for filters defined for each path name. These path names are valid in the INCLUDE_PATH_EXPR and EXCLUDE_PATH_EXPR filters. Path names marked with an asterisk (*) are *only* valid in those filters; they cannot be used as values of the SET_FILTER object_type_path parameter.

Table 112-19 Object Type Path Names for Heterogeneous Object Types

Heterogeneous Type	Path Name (*=valid only in xxx_PATH_EXPR)	Scope
TABLE_EXPORT	AUDIT_OBJ	Object audits on the selected tables
TABLE_EXPORT	COMMENT	Table and column comments for the selected tables
TABLE_EXPORT	CONSTRAINT	Constraints (including referential constraints) on the selected tables
TABLE_EXPORT	*GRANT	Object grants on the selected tables
TABLE_EXPORT	INDEX	Indexes (including domain indexes) on the selected tables
TABLE_EXPORT	OBJECT_GRANT	Object grants on the selected tables
TABLE_EXPORT	REF_CONSTRAINT	Referential (foreign key) constraints on the selected tables
TABLE_EXPORT	STATISTICS	Statistics on the selected tables
TABLE_EXPORT	TABLE_DATA	Row data for the selected tables
TABLE_EXPORT	TRIGGER	Triggers on the selected tables
SCHEMA_EXPORT	ASSOCIATION	Statistics type associations for objects in the selected schemas
SCHEMA_EXPORT	AUDIT_OBJ	Audits on all objects in the selected schemas
SCHEMA_EXPORT	CLUSTER	Clusters in the selected schemas and their indexes
SCHEMA_EXPORT	COMMENT	Comments on all objects in the selected schemas
SCHEMA_EXPORT	CONSTRAINT	Constraints (including referential constraints) on all objects in the selected schemas

Table 112-19 (Cont.) Object Type Path Names for Heterogeneous Object Types

Heterogeneous Type	Path Name (*=valid only in xxx_PATH_EXPR)	Scope
SCHEMA_EXPORT	DB_LINK	Private database links in the selected schemas
SCHEMA_EXPORT	DEFAULT_ROLE	Default roles granted to users associated with the selected schemas
SCHEMA_EXPORT	DIMENSION	Dimensions in the selected schemas
SCHEMA_EXPORT	FUNCTION	Functions in the selected schemas and their dependent grants and audits
SCHEMA_EXPORT	*GRANT	Grants on objects in the selected schemas
SCHEMA_EXPORT	INDEX	Indexes (including domain indexes) on tables and clusters in the selected schemas
SCHEMA_EXPORT	INDEXTYPE	Indextypes in the selected schemas and their dependent grants and audits
SCHEMA_EXPORT	JAVA_SOURCE	Java sources in the selected schemas and their dependent grants and audits
SCHEMA_EXPORT	JOB	Jobs in the selected schemas
SCHEMA_EXPORT	LIBRARY	External procedure libraries in the selected schemas
SCHEMA_EXPORT	MATERIALIZED_VIEW	Materialized views in the selected schemas
SCHEMA_EXPORT	MATERIALIZED_VIEW_LOG	Materialized view logs on tables in the selected schemas
SCHEMA_EXPORT	OBJECT_GRANT	Grants on objects in the selected schemas
SCHEMA_EXPORT	OPERATOR	Operators in the selected schemas and their dependent grants and audits
SCHEMA_EXPORT	PACKAGE	Packages (both specification and body) in the selected schemas, and their dependent grants and audits
SCHEMA_EXPORT	PACKAGE_BODY	Package bodies in the selected schemas
SCHEMA_EXPORT	PACKAGE_SPEC	Package specifications in the selected schemas
SCHEMA_EXPORT	PASSWORD_HISTORY	The password history for users associated with the selected schemas
SCHEMA_EXPORT	PROCEDURE	Procedures in the selected schemas and their dependent grants and audits
SCHEMA_EXPORT	REF_CONSTRAINT	Referential (foreign key) constraints on tables in the selected schemas
SCHEMA_EXPORT	REFRESH_GROUP	Refresh groups in the selected schemas
SCHEMA_EXPORT	SEQUENCE	Sequences in the selected schemas and their dependent grants and audits
SCHEMA_EXPORT	STATISTICS	Statistics on tables and indexes in the selected schemas
SCHEMA_EXPORT	SYNONYM	Private synonyms in the selected schemas
SCHEMA_EXPORT	TABLE	Tables in the selected schemas and their dependent objects (indexes, constraints, triggers, grants, audits, comments, table data, and so on)
SCHEMA_EXPORT	TABLE_DATA	Row data for tables in the selected schemas

Table 112-19 (Cont.) Object Type Path Names for Heterogeneous Object Types

Heterogeneous Type	Path Name (*=valid only in xxx_PATH_EXPR)	Scope
SCHEMA_EXPORT	TABLESPACE_QUOTA	Tablespace quota granted to users associated with the selected schemas
SCHEMA_EXPORT	TRIGGER	Triggers on tables in the selected schemas
SCHEMA_EXPORT	XS_SECURITY_CLASS	Oracle Real Application Security (RAS) security classes
SCHEMA_EXPORT	XS_DATA_SECURITY	Oracle Real Application Security (RAS) data security policies
SCHEMA_EXPORT	XS_ACL	Oracle Real Application Security (RAS) access control lists (ACLs)
SCHEMA_EXPORT	TYPE	Types (both specification and body) in the selected schemas, and their dependent grants and audits
SCHEMA_EXPORT	TYPE_BODY	Type bodies in the selected schemas
SCHEMA_EXPORT	TYPE_SPEC	Type specifications in the selected schemas
SCHEMA_EXPORT	USER	User definitions for users associated with the selected schemas
SCHEMA_EXPORT	VIEW	Views in the selected schemas and their dependent objects (grants, constraints, comments, audits)
DATABASE_EXPORT	ASSOCIATION	Statistics type associations for objects in the database
DATABASE_EXPORT	AUDIT	Audits of SQL statements
DATABASE_EXPORT	AUDIT_OBJ	Audits on all objects in the database
DATABASE_EXPORT	CLUSTER	Clusters and their indexes
DATABASE_EXPORT	COMMENT	Comments on all objects
DATABASE_EXPORT	CONSTRAINT	Constraints (including referential constraints)
DATABASE_EXPORT	CONTEXT	Application contexts
DATABASE_EXPORT	DB_LINK	Private and public database links
DATABASE_EXPORT	DEFAULT_ROLE	Default roles granted to users in the database
DATABASE_EXPORT	DIMENSION	Dimensions in the database
DATABASE_EXPORT	DIRECTORY	Directory objects in the database
DATABASE_EXPORT	FGA_POLICY	Fine-grained audit policies
DATABASE_EXPORT	FUNCTION	Functions
DATABASE_EXPORT	* GRANT	Object and system grants
DATABASE_EXPORT	INDEX	Indexes (including domain indexes) on tables and clusters
DATABASE_EXPORT	INDEXTYPE	Indextypes and their dependent grants and audits
DATABASE_EXPORT	JAVA_SOURCE	Java sources and their dependent grants and audits
DATABASE_EXPORT	JOB	Jobs
DATABASE_EXPORT	LIBRARY	External procedure libraries
DATABASE_EXPORT	MATERIALIZED_VIEW	Materialized views

Table 112-19 (Cont.) Object Type Path Names for Heterogeneous Object Types

Heterogeneous Type	Path Name (*=valid only in xxx_PATH_EXPR)	Scope
DATABASE_EXPORT	MATERIALIZED_VIEW_LOG	Materialized view logs
DATABASE_EXPORT	OBJECT_GRANT	All object grants in the database
DATABASE_EXPORT	OPERATOR	Operators and their dependent grants and audits
DATABASE_EXPORT	PACKAGE	Packages (both specification and body) and their dependent grants and audits
DATABASE_EXPORT	PACKAGE_BODY	Package bodies
DATABASE_EXPORT	PACKAGE_SPEC	Package specifications
DATABASE_EXPORT	PASSWORD_HISTORY	Password histories for database users
DATABASE_EXPORT	*PASSWORD_VERIFY_FUNCTION	The password complexity verification function
DATABASE_EXPORT	PROCEDURE	Procedures and their dependent grants and objects
DATABASE_EXPORT	PROFILE	Profiles
DATABASE_EXPORT	PROXY	Proxy authentications
DATABASE_EXPORT	REF_CONSTRAINT	Referential (foreign key) constraints on tables in the database
DATABASE_EXPORT	REFRESH_GROUP	Refresh groups
DATABASE_EXPORT	*RESOURCE_ COST	Resource cost information
DATABASE_EXPORT	RLS_CONTEXT	Fine-grained access-control driving contexts
DATABASE_EXPORT	RLS_GROUP	Fine-grained access-control policy groups
DATABASE_EXPORT	RLS_POLICY	Fine-grained access-control policies
DATABASE_EXPORT	ROLE	Roles
DATABASE_EXPORT	ROLE_GRANT	Role grants to users in the database
DATABASE_EXPORT	ROLLBACK_SEGMENT	Rollback segments
DATABASE_EXPORT	*SCHEMA (named object)	Database schemas including for each schema all related and dependent objects: user definitions and their attributes (default roles, role grants, tablespace quotas, and so on), objects in the schema (tables, view, packages, types, and so on), and their dependent objects (grants, audits, indexes, constraints, and so on). The NAME and NAME_EXPR filters can be used with this object type path name to designate the database schemas to be fetched.
DATABASE_EXPORT	SEQUENCE	Sequences
DATABASE_EXPORT	STATISTICS	Statistics on tables and indexes
DATABASE_EXPORT	SYNONYM	Public and private synonyms
DATABASE_EXPORT	SYSTEM_GRANT	System privilege grants
DATABASE_EXPORT	TABLE	Tables and their dependent objects (indexes, constraints, triggers, grants, audits, comments, table data, and so on)
DATABASE_EXPORT	TABLE_DATA	Row data for all tables
DATABASE_EXPORT	TABLESPACE	Tablespace definitions

Table 112-19 (Cont.) Object Type Path Names for Heterogeneous Object Types

Heterogeneous Type	Path Name (*=valid only in xxx_PATH_EXPR)	Scope
DATABASE_EXPORT	TABLESPACE_QUOTA	Tablespace quota granted to users in the database
DATABASE_EXPORT	TRIGGER	Triggers on the database, on schemas, and on schema objects
DATABASE_EXPORT	XS_USER	Oracle Real Application Security (RAS) users
DATABASE_EXPORT	XS_ROLE	Oracle Real Application Security (RAS) roles
DATABASE_EXPORT	XS_SECURITY_CLASS	Oracle Real Application Security (RAS) security classes
DATABASE_EXPORT	XS_DATA_SECURITY	Oracle Real Application Security (RAS) data security policies
DATABASE_EXPORT	XS_ACL	Oracle Real Application Security (RAS) access control lists (ACLs)
DATABASE_EXPORT	XS_NAMESPACE	Oracle Real Application Security (RAS) namespaces
DATABASE_EXPORT	TRUSTED_DB_LINK	Trusted links
DATABASE_EXPORT	TYPE	Types (both specification and body) and their dependent grants and audits
DATABASE_EXPORT	TYPE_BODY	Type bodies
DATABASE_EXPORT	TYPE_SPEC	Type specifications
DATABASE_EXPORT	USER	User definitions
DATABASE_EXPORT	VIEW	Views

Exceptions

- `INVALID_ARGVAL`. A `NULL` or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- `INVALID_OPERATION`. `SET_FILTER` was called after the first call to `FETCH_xxx` for the `OPEN` context. After the first call to `FETCH_xxx` is made, no further calls to `SET_FILTER` are permitted.
- `INCONSISTENT_ARGS`. The arguments are inconsistent. Possible inconsistencies include the following:
  - The filter name is not valid for the object type associated with the `OPEN` context.
  - The filter `name` is not valid for the `object_type_path`.
  - The `object_type_path` is not part of the collection designated by `handle` .
  - The filter `value` is the wrong datatype.

112.6.12 SET_PARSE_ITEM Procedure

This procedure is used for both retrieval and submission. This procedure enables output parsing and specifies an object attribute to be parsed and returned.

> **See Also:**
>
> For more information about related subprograms:
>
> - Subprograms for Retrieving Multiple Objects From the Database
> - Subprograms for Submitting XML to the Database

Syntax

The following syntax applies when SET_PARSE_ITEM is used for object retrieval:

```
DBMS_METADATA.SET_PARSE_ITEM (
   handle       IN  NUMBER,
   name         IN  VARCHAR2,
   object_type  IN  VARCHAR2 DEFAULT NULL);
```

The following syntax applies when SET_PARSE_ITEM is used for XML submission:

```
DBMS_METADATA.SET_PARSE_ITEM (
   handle     IN NUMBER,
   name        IN VARCHAR2);
```

Parameters

Table 112-20 SET_PARSE_ITEM Procedure Parameters

Parameter	Description
handle	The handle returned from OPEN (or OPENW).
name	The name of the object attribute to be parsed and returned. See Table 112-21 for the attribute object type, name, and meaning.
object_type	Designates the object type to which the parse item applies (this is an object type name, not a path name). By default, the parse item applies to the object type of the OPEN handle. When the OPEN handle designates a heterogeneous object type, behavior can be either of the following: • If object_type is omitted, then the parse item applies to all object types within the heterogeneous collection . • If object_type is specified, then the parse item only applies to that specific object type within the collection . This parameter only applies when SET_PARSE_ITEM is used for object retrieval.

Table 112-21 describes the object type, name, and meaning of the items available in the SET_PARSE_ITEM procedure.

Because new items are occasionally added, you can query the DBMS_METADATA_PARSE_ITEMS view to see a complete list of valid parse items or to find valid parse items for a specific object type.

Table 112-21 SET_PARSE_ITEM: Parse Items

Object Type	Name	Meaning
All objects	VERB	If FETCH_XML_CLOB is called, no value is returned. If FETCH_DDL is called, then for every row in the sys.ku$_ddls nested table returned by FETCH_DDL the verb in the corresponding ddlText is returned. If the ddlText is a SQL DDL statement, then the SQL verb (for example, CREATE, GRANT, AUDIT) is returned. If the ddlText is a procedure call (for example, DBMS_AQADM.CREATE_QUEUE_TABLE( )) then the package.procedure-name is returned.
All objects	OBJECT_TYPE	If FETCH_XML_CLOB is called, an object type name from Table 112-12 is returned. If FETCH_DDL is called and the ddlText is a SQL DDL statement whose verb is CREATE or ALTER, the object type as used in the DDL statement is returned (for example, TABLE, PACKAGE_BODY, and so on). Otherwise, an object type name from Table 112-12 is returned.
Schema objects	SCHEMA	The object schema is returned. If the object is not a schema object, no value is returned.
Named objects	NAME	The object name is returned. If the object is not a named object, no value is returned.
TABLE, TABLE_DATA, INDEX	TABLESPACE	The name of the object's tablespace or, if the object is a partitioned table, the default tablespace is returned. For a TABLE_DATA object, this is always the tablespace where the rows are stored.
TRIGGER	ENABLE	If the trigger is enabled, ENABLE is returned. If the trigger is disabled, DISABLE is returned.
OBJECT_GRANT, TABLESPACE_QUOTA	GRANTOR	The grantor is returned.
Dependent objects (including domain index secondary tables)	BASE_OBJECT_NAME	The name of the base object is returned. If the object is not a dependent object, no value is returned.
Dependent objects (including domain index secondary tables)	BASE_OBJECT_SCHEMA	The schema of the base object is returned. If the object is not a dependent object, no value is returned.
Dependent objects (including domain index secondary tables)	BASE_OBJECT_TYPE	The object type of the base object is returned. If the object is not a dependent object, no value is returned.
Granted objects	GRANTEE	The grantee is returned. If the object is not a granted object, no value is returned.

Usage Notes

These notes apply when using SET_PARSE_ITEM to retrieve objects.

By default, the FETCH_xxx routines return an object's metadata as XML or creation DDL. By calling SET_PARSE_ITEM you can request that individual attributes of the object be returned as well.

You can call SET_PARSE_ITEM multiple times to ask for multiple items to be parsed and returned. Parsed items are returned in the sys.ku$_parsed_items nested table.

For TABLE_DATA objects, the following parse item return values are of interest:

If Object Is	NAME, SCHEMA	BASE_OBJECT_NAME, BASE_OBJECT_SCHEMA
nonpartitioned table	table name, schema	table name, schema
table partition	partition name, schema	table name, schema
nested table	storage table name, schema	name and schema of top-level table (*not* the parent nested table)

Tables are not usually thought of as dependent objects. However, secondary tables for domain indexes are dependent on the domain indexes. Consequently, the BASE_OBJECT_NAME, BASE_OBJECT_SCHEMA and BASE_OBJECT_TYPE parse items for secondary TABLE objects return the name, schema, and type of the domain index.

- "FETCH_xxx Functions and Procedures"
- *Oracle Database Utilities* for more information about using the metadata APIs.

By default, the CONVERT and PUT procedures simply transform an object's XML metadata to DDL. By calling SET_PARSE_ITEM you can request that individual attributes of the object be returned as well.

Exceptions

- INVALID_ARGVAL. A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- INVALID_OPERATION. SET_PARSE_ITEM was called after the first call to FETCH_xxx for the OPEN context. After the first call to FETCH_xxx is made, no further calls to SET_PARSE_ITEM are permitted.
- INCONSISTENT_ARGS. The attribute name is not valid for the object type associated with the OPEN context.

112.6.13 SET_TRANSFORM_PARAM and SET_REMAP_PARAM Procedures

These procedures are used for both retrieval and submission. SET_TRANSFORM_PARAM and SET_REMAP_PARAM specify parameters to the XSLT stylesheet identified by transform_handle.

Use them to modify or customize the output of the transform.

> **See Also:**
>

> - Subprograms for Submitting XML to the Database

Syntax

```
DBMS_METADATA.SET_TRANSFORM_PARAM (
   transform_handle   IN NUMBER,
   name               IN VARCHAR2,
   value              IN VARCHAR2,
   object_type        IN VARCHAR2 DEFAULT NULL);

DBMS_METADATA.SET_TRANSFORM_PARAM (
   transform_handle   IN NUMBER,
   name               IN VARCHAR2,
   value              IN BOOLEAN DEFAULT TRUE,
   object_type        IN VARCHAR2 DEFAULT NULL);

DBMS_METADATA.SET_TRANSFORM_PARAM (
   transform_handle   IN NUMBER,
   name               IN VARCHAR2,
   value              IN NUMBER,
   object_type        IN VARCHAR2 DEFAULT NULL);

DBMS_METADATA.SET_REMAP_PARAM (
   transform_handle   IN NUMBER,
   name               IN VARCHAR2,
   old_value          IN VARCHAR2,
   new_value          IN VARCHAR2,
   object_type        IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 112-22 describes the parameters for the SET_TRANSFORM_PARAM and SET_REMAP_PARAM procedures.

Because new parameters are occasionally added, you might want to query the DBMS_METADATA_TRANSFORM_PARAMS view to see all the valid transform parameters for each transform or to find valid transform parameters for specific object types.

Table 112-22 SET_TRANSFORM_PARAM and SET_REMAP_PARAM Parameters

Parameters	Description
transform_handle	Either (1) the handle returned from ADD_TRANSFORM, or (2) the enumerated constant SESSION_TRANSFORM that designates the DDL transform for the whole session. Note that the handle returned by OPEN is not a valid transform handle. For SET_REMAP_PARAM, the transform handle must designate the MODIFY transform.

Table 112-22 (Cont.) SET_TRANSFORM_PARAM and SET_REMAP_PARAM Parameters

Parameters	Description
name	The name of the transform parameter. For descriptions of the parameters available for each transform on the SET_TRANSFORM_PARAM procedure, see the following: Table 112-23 - DDL transform Table 112-24 - MODIFY transform Table 112-26 - SXML transform Table 112-27 - MODIFYSXML transform Table 112-28 - SXMLDDL transform For descriptions of the parameters available for the MODIFY transform on the SET_REMAP_PARAM procedure, see Table 112-25. For descriptions of the parameters available for the ALTERXML transform, see Table 112-4.
value	The value of the transform. This parameter is valid only for SET_TRANSFORM_PARAM.
old_value	The old value for the remapping. This parameter is valid only for SET_REMAP_PARAM.
new_value	The new value for the remapping. This parameter is valid only for SET_REMAP_PARAM.
object_type	Designates the object type to which the transform or remap parameter applies. By default, it applies to the same object type as the transform. In cases where the transform applies to all object types within a heterogeneous collection, the following apply: • If object_type is omitted, the parameter applies to all applicable object types within the heterogeneous collection. • If object_type is specified, the parameter only applies to that object type. This allows a caller who has added a transform to a heterogeneous collection to specify different transform parameters for different object types within the collection.

Table 112-23 describes the object type, name, datatype, and meaning of the parameters for the DDL transform in the SET_TRANSFORM_PARAM procedure.

Table 112-23 SET_TRANSFORM_PARAM: Transform Parameters for the DDL Transform

Object Type	Name	Datatype	Meaning
USER, TABLE, CLUSTER, VIEW, MATERIALIZED_VIEW PROCEDURE, FUNCTION, PACKAGE, TYPE, TRIGGER	COLLATION_CLAUSE	Text	There are three possible values: • NEVER — Collation clauses are never generated. • ALWAYS — Collation clauses are always generated. • NON_DEFAULT — Collation clauses other than USING_NLS_COMP are generated.

Table 112-23 (Cont.) SET_TRANSFORM_PARAM: Transform Parameters for the DDL Transform

Object Type	Name	Datatype	Meaning
TABLE	OMIT_ENCRYPTION_CLAUSE	BOOLEAN	If set to Y, directs Data Pump to suppress column encryption clauses. Columns encrypted in the source database are not encrypted in imported tables. Defaults to N. If set to N, directs Data Pump to create column encryption clauses, as in the source database.
TABLE	DWCS_CVT_IOTS	BOOLEAN	If set to Y, directs Data Pump to transform Index Organized tables to heap organized tables by suppressing the ORGANIZATION INDEX clause when creating the table. Defaults to N. If set to N, the generated DDL retains the table characteristics of the source object.
TABLE, CONSTRAINT	DWCS_CVT_CONSTRAINTS	BOOLEAN	If set to Y, directs Data Pump to create pk/fk/uk constraints as disabled. Defaults to N. If set to N, directs Data Pump to create pk/fk/uk constraints based on the source database status.
TABLE, CONSTRAINT	CONSTRAINT_USE_DEFAULT_INDEX	BOOLEAN	This transform parameter affects the generation of index relating the pk/uk constraint. If set to Y, forces the name of an index automatically created to enforce the constraint to be identical to the constraint name. Defaults to N. If set to N, the index is created as it was named on the source database.
TABLE, CONSTRAINT	CONSTRAINT_NAME_FROM_INDEX	BOOLEAN	This transform parameter affects the generation of pk/uk constraints which reference user created indexes. If set to Y, forces the name of the constraint to match the name of the index. Defaults to N. If set to N, the constraint is created as it was named on the source database.
All objects	PRETTY	BOOLEAN	If TRUE, format the output with indentation and line feeds. Defaults to TRUE.
All objects	SQLTERMINATOR	BOOLEAN	If TRUE, append a SQL terminator (; or /) to each DDL statement. Defaults to FALSE.
TABLE	CONSTRAINTS	BOOLEAN	If TRUE, include all non-referential table constraints in the DDL. If FALSE, omit them. Defaults to TRUE.
TABLE	REF_CONSTRAINTS	BOOLEAN	If TRUE, include all referential constraints (foreign keys) in the DDL. If FALSE, omit them. Defaults to TRUE.

Table 112-23 (Cont.) SET_TRANSFORM_PARAM: Transform Parameters for the DDL Transform

Object Type	Name	Datatype	Meaning
TABLE	CONSTRAINTS_AS_ALTER	BOOLEAN	If TRUE, include table constraints as separate ALTER TABLE (and, if necessary, CREATE INDEX) statements. If FALSE, specify table constraints as part of the CREATE TABLE statement. Defaults to FALSE. Requires that CONSTRAINTS be TRUE.
TABLE, TYPE	OID	BOOLEAN	If TRUE, include the Object ID (OID) clause in the DDL. If FALSE, omit it. Defaults to FALSE.
TABLE	SIZE_BYTE_KEYWORD	BOOLEAN	If TRUE, include the BYTE keyword as part of the size specification of CHAR and VARCHAR2 columns that use byte semantics. If FALSE, omit the keyword. Defaults to FALSE.
TABLE, INDEX	PARTITIONING	BOOLEAN	If TRUE, include partitioning clauses in the DDL. If FALSE, omit them. Defaults to TRUE.
INDEX, CONSTRAINT, ROLLBACK_SEGMENT, CLUSTER, TABLE, TABLESPACE	SEGMENT_ATTRIBUTES	BOOLEAN	If TRUE, include segment attributes clauses (physical attributes, storage attributes, tablespace, logging) in the DDL. If FALSE, omit them. Defaults to TRUE.
INDEX, CONSTRAINT, ROLLBACK_SEGMENT, CLUSTER, TABLE	STORAGE	BOOLEAN	If TRUE, include storage clauses in the DDL. If FALSE, omit them. (Ignored if SEGMENT_ATTRIBUTES is FALSE.) Defaults to TRUE.
INDEX, CONSTRAINT, ROLLBACK_SEGMENT, CLUSTER, TABLE	TABLESPACE	BOOLEAN	If TRUE, include tablespace clauses in the DDL. If FALSE, omit them. (Ignored if SEGMENT_ATTRIBUTES is FALSE.) Defaults to TRUE.
TYPE, PACKAGE	SPECIFICATION	BOOLEAN	If TRUE, include the type or package specification in the DDL. If FALSE, omit it. Defaults to TRUE.
TYPE, PACKAGE	BODY	BOOLEAN	If TRUE, include the type body or package body in the DDL. If FALSE, omit it. Defaults to TRUE.
VIEW	FORCE	BOOLEAN	If TRUE, use the FORCE keyword in the CREATE VIEW statement. If FALSE, do not use the FORCE keyword in the CREATE VIEW statement. Defaults to TRUE.

Table 112-23 (Cont.) SET_TRANSFORM_PARAM: Transform Parameters for the DDL Transform

Object Type	Name	Datatype	Meaning
OUTLINE	INSERT	BOOLEAN	If TRUE, include the INSERT statements into the OL$ dictionary tables that will create the outline and its hints. If FALSE, omit a CREATE OUTLINE statement. Defaults to FALSE. Note: This object type is being deprecated.
All objects	DEFAULT	BOOLEAN	Calling SET_TRANSFORM_PARAM with this parameter set to TRUE has the effect of resetting all parameters for the transform to their default values. Setting this FALSE has no effect. There is no default.
All objects	INHERIT	BOOLEAN	If TRUE, inherits session-level parameters. Defaults to FALSE. If an application calls ADD_TRANSFORM to add the DDL transform, then by default the only transform parameters that apply are those explicitly set for that transform handle. This has no effect if the transform handle is the session transform handle.
ROLE	REVOKE_FROM	Text	The name of a user from whom the role must be revoked. If this is a non-null string and if the CREATE ROLE statement grants you the role, a REVOKE statement is included in the DDL after the CREATE ROLE statement. Note: When you issue a CREATE ROLE statement, Oracle may grant you the role. You can use this transform parameter to undo the grant. Defaults to null string.
TABLESPACE	REUSE	BOOLEAN	If TRUE, include the REUSE parameter for datafiles in a tablespace to indicate that existing files can be reused. If FALSE, omit the REUSE parameter. Defaults to FALSE.

Table 112-23 (Cont.) SET_TRANSFORM_PARAM: Transform Parameters for the DDL Transform

Object Type	Name	Datatype	Meaning
CLUSTER, INDEX, ROLLBACK_SEGMENT, TABLE, TABLESPACE	PCTSPACE	NUMBER	A number representing the percentage by which space allocation for the object type is to be modified. The value is the number of one-hundredths of the current allocation. For example, 100 means 100%. If the object type is TABLESPACE, the following size values are affected: - in file specifications, the value of SIZE - MINIMUM EXTENT - EXTENT MANAGEMENT LOCAL UNIFORM SIZE For other object types, INITIAL and NEXT are affected.
TABLE	LOB_STORAGE	Text	Specifies the storage type to use for LOB segments. The options are as follows: • SECUREFILE - LOB storage is returned as SECUREFILE • BASICFILE - LOB storage is returned as BASICFILE • DEFAULT - The keyword (SECUREFILE or BASICFILE) is omitted in the LOB STORE AS clause. • NO_CHANGE - LOB segments are created with the same storage they had in the source database. This is the default. Specifying this transform changes the LOB storage for all tables in the job, including tables that provide storage for materialized views.
TABLE	TABLE_COMPRESSION_CLAUSE	Text	Specifies a table compression clause (for example, COMPRESS BASIC) to use when the table is created. Specify NONE to omit the table compression clause. The table will have the default compression for the tablespace. Specifying this transform changes the compression type for all tables in the job, including tables that provide storage for materialized views.

Table 112-24 describes the object type, name, datatype, and meaning of the parameters for the MODIFY transform in the SET_TRANSFORM_PARAM procedure.

Table 112-24 SET_TRANSFORM_PARAM: Transform Parameters for the MODIFY Transform

Object Type	Name	Datatype	Meaning
All objects	OBJECT_ROW	NUMBER	A number designating the object row for an object. The object in the document that corresponds to this number will be copied to the output document. This parameter is additive. By default, all objects are copied to the output document.

Table 112-25 describes the object type, name, datatype, and meaning of the parameters for the MODIFY transform in the SET_REMAP_PARAM procedure.

Table 112-25 SET_REMAP_PARAM: Transform Parameters for the MODIFY Transform

Object Type	Name	Datatype	Meaning
LIBRARY, TABLESPACE, DIRECTORY	REMAP_DATAFILE	Text	Objects in the document will have their filespecs renamed as follows: any filespec matching old_value will be changed to new_value. Filespecs should *not* be enclosed in quotes. This parameter is additive. By default, filespecs are not renamed.
Named objects and all objects dependent on named objects	REMAP_NAME	Text	Any named object in the document whose name matches old_value will have its name changed to new_value. Any dependent object whose base object name matches old_value will have its base schema name changed to new_value. This parameter is additive. By default, names are not remapped. (Use REMAP_TABLESPACE to remap the name of a TABLESPACE object.)

Table 112-25 (Cont.) SET_REMAP_PARAM: Transform Parameters for the MODIFY Transform

Object Type	Name	Datatype	Meaning
Schema Objects, Dependent Objects, Granted Objects, USER	REMAP_SCHEMA	Text	Any schema object in the document whose name matches old_value will have its schema name changed to new_value. Any dependent object whose base object schema name matches old_value will have its base object schema name changed to new_value. Any granted object whose grantee name matches old_value will have its grantee name changed to new_value. Any user whose name matches old_value will have its name changed to new_value. This parameter is additive. By default, schemas are not remapped. NOTE: The mapping may not be 100 percent complete because there are certain schema references that Import is not capable of finding. For example, Import will not find schema references embedded within the body of definitions of triggers, types, views, procedures, and packages.
TABLE, CLUSTER, CONSTRAINT, INDEX, ROLLBACK_SEGMENT, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG, TABLESPACE_QUOTA	REMAP_TABLESPACE	Text	Objects in the document will have their tablespaces renamed as follows: any tablespace name matching old_value will be changed to new_value. This parameter is additive. By default, tablespaces are not remapped.

Table 112-26 SET_TRANSFORM_PARAM: Transform Parameters for the SXML Transform

Object type	Name	Datatype	Meaning
USER, TABLE, CLUSTER, VIEW, MATERIALIZED_VIEW PROCEDURE, FUNCTION, PACKAGE, TYPE, TRIGGER	COLLATION_CLAUSE	Text	There are three possible values: • NEVER — Collation clauses are never generated. • ALWAYS — Collation clauses are always generated. • NON_DEFAULT — Collation clauses other than USING_NLS_COMP are generated.
TABLE, TYPE	OID	Boolean	If TRUE, include the Oracle Internet Directory (OID) clause in the SXML. If FALSE, omit it. Defaults to FALSE.

Table 112-26 (Cont.) SET_TRANSFORM_PARAM: Transform Parameters for the SXML Transform

Object type	Name	Datatype	Meaning
TABLE, INDEX, CLUSTER, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG.	STORAGE	Boolean	If TRUE, include storage clauses in the SXML. If FALSE, omit them. (Ignored if SEGMENT_ATTRIBUTES is FALSE.) Defaults to TRUE.
TABLE, INDEX, CLUSTER, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG.	TABLESPACE	Boolean	If TRUE, include tablespace clauses in the SXML. If FALSE, omit them. (Ignored if SEGMENT_ATTRIBUTES is FALSE.) Defaults to TRUE.
TABLE	REF_CONSTRAINTS	Boolean	If TRUE, include all referential constraints (foreign keys) in the SXML. If FALSE, omit them. Defaults to TRUE.
TABLE, INDEX, MATERIALIZED_VIEW	PHYSICAL_PROPERTIES	Boolean	If TRUE, include segment attributes clauses (physical attributes, storage attributes, tablespace, logging) in the SXML. If FALSE, omit them. Defaults to TRUE.
INDEX, CONSTRAINT, ROLLBACK_SEGMENT, CLUSTER, TABLE, TABLESPACE	SEGMENT_ATTRIBUTES	Boolean	If TRUE, include segment attributes clauses (physical attributes, storage attributes, tablespace, logging) in the SXML. If FALSE, omit them. Defaults to TRUE.
TABLE, INDEX	PARTITIONING	Boolean	If TRUE, include partitioning clauses in the SXML. If FALSE, omit them. Defaults to TRUE.
TABLE	CONSTRAINTS	Boolean	If TRUE, include all non-referential table constraints in the SXML. If FALSE, omit them. Defaults to TRUE.

Table 112-27 SET_TRANSFORM_PARAM: Transform Parameters for the MODIFYSXML Transform

Object type	Name	Datatype	Meaning
TABLE, INDEX, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG	STORAGE	Boolean	If TRUE, include storage clauses in the output SXML. If FALSE, omit them. (Ignored if SEGMENT_ATTRIBUTES is FALSE.) Defaults to TRUE.
TABLE, INDEX, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG	TABLESPACE	Boolean	If TRUE, include tablespace clauses in the output SXML. If FALSE, omit them. (Ignored if SEGMENT_ATTRIBUTES is FALSE.) Defaults to TRUE.

Table 112-27 (Cont.) SET_TRANSFORM_PARAM: Transform Parameters for the MODIFYSXML Transform

Object type	Name	Datatype	Meaning
TABLE	REF_CONSTRAINTS	Boolean	If TRUE, include all referential constraints (foreign keys) in the output SXML. If FALSE, omit them. Defaults to TRUE.
TABLE, INDEX, VIEW, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG	REMAP_NAME	Text	Any NAME element in the document that matches old_value will be changed to new_value. This does not apply to column names. (See REMAP_COLUMN_NAME).
TABLE, INDEX, VIEW, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG	REMAP_SCHEMA	Text	Any SCHEMA element in the document matching old_value will be changed to new_value.
TABLE, INDEX, VIEW, MATERIALIZED_VIEW	REMAP_COLUMN_NAME	Text	Any column in the document whose name matches old_value will have its name changed to new_value.
TABLE, INDEX, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG	SEGMENT_ATTRIBUTES	Boolean	If TRUE, include segment attributes clauses (physical attributes, storage attributes, tablespace, logging) in the output SXML. If FALSE, omit them. Defaults to TRUE.
TABLE	CONSTRAINTS	Boolean	If TRUE, include all non-referential table constraints in the output SXML. If FALSE, omit them. Defaults to TRUE.

Table 112-28 SET_TRANSFORM_PARAM: Transform Parameters for the SXMLDDL Transform

Object type	Name	Datatype	Meaning
USER, TABLE, CLUSTER, VIEW, MATERIALIZED_VIEW PROCEDURE, FUNCTION, PACKAGE, TYPE, TRIGGER	COLLATION_CLAUSE	Text	There are three possible values: • NEVER — Collation clauses are never generated. • ALWAYS — Collation clauses are always generated. • NON_DEFAULT — Collation clauses other than USING_NLS_COMP are generated.
TABLE	OID	Boolean	If TRUE, include OIDs in the DDL. If FALSE, omit them. (Ignored if SEGMENT_ATTRIBUTES is FALSE.) Defaults to TRUE.
TABLE, INDEX, CLUSTER, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG.	TABLESPACE	Boolean	If TRUE, include tablespace clauses in the DDL. If FALSE, omit them. (Ignored if SEGMENT_ATTRIBUTES is FALSE.) Defaults to TRUE.

Table 112-28 (Cont.) SET_TRANSFORM_PARAM: Transform Parameters for the SXMLDDL Transform

Object type	Name	Datatype	Meaning
TABLE, INDEX, CLUSTER, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG	STORAGE	Boolean	If TRUE, include storage clauses in the DDL. If FALSE, omit them. (Ignored if SEGMENT_ATTRIBUTES is FALSE.) Defaults to TRUE.
TABLE	REF_CONSTRAINTS	Boolean	If TRUE, include all referential constraints (foreign keys) in the DDL. If FALSE, omit them. Defaults to TRUE.
INDEX	PRESERVE_LOCAL	Boolean	If PARTITIONING is FALSE and PRESERVE_LOCAL is TRUE and the index is a locally partitioned index, include the LOCAL keyword in the DDL. Defaults to FALSE.
TABLE, INDEX, CLUSTER, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG	SEGMENT_ATTRIBUTES	Boolean	If TRUE, include segment attributes clauses (physical attributes, storage attributes, tablespace, logging) in the DDL. If FALSE, omit them. Defaults to TRUE.
TABLESPACE	REUSE	Boolean	If TRUE, include the REUSE parameter for datafiles in a tablespace to indicate that existing files can be reused. If FALSE, omit the REUSE parameter. Defaults to FALSE.
TABLE, INDEX	PARTITIONING	Boolean	If TRUE, include partitioning clauses in the DDL. If FALSE, omit them. Defaults to TRUE.
TABLE	CONSTRAINTS	Boolean	If TRUE, include all non-referential table constraints in the output SXML. If FALSE, omit them. Defaults to TRUE.

Exceptions

- INVALID_ARGVAL. A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- INVALID_OPERATION. Either SET_TRANSFORM_PARAM or SET_REMAP_PARAM was called after the first call to FETCH_xxx for the OPEN context. After the first call to FETCH_xxx is made, no further calls to SET_TRANSFORM_PARAM or SET_REMAP_PARAM are permitted.
- INCONSISTENT_ARGS. The arguments are inconsistent. This can mean the following:
  - The transform parameter name is not valid for the object type associated with the OPEN context or for the transform associated with the transform handle.
  - The transform applies to all object types in a heterogeneous collection, but object_type is not part of the collection.

Usage Notes

XSLT allows parameters to be passed to stylesheets. You call SET_TRANSFORM_PARAM or SET_REMAP_PARAM to specify the value of a parameter to be passed to the stylesheet identified by transform_handle.

Normally, if you call SET_TRANSFORM_PARAMETER multiple times for the same parameter name, each call overrides the prior call. For example, the following sequence simply sets the STORAGE transform parameter to TRUE.

```
SET_TRANSFORM_PARAM(tr_handle,'STORAGE',false);
SET_TRANSFORM_PARAM(tr_handle,'STORAGE',true);
```

However, some transform parameters are additive which means that all specified parameter values are applied to the document, not just the last one. For example, the OBJECT_ROW parameter to the MODIFY transform is additive. If you specify the following, then both specified rows are copied to the output document.

```
SET_TRANSFORM_PARAM(tr_handle,'OBJECT_ROW',5);
SET_TRANSFORM_PARAM(tr_handle,'OBJECT_ROW',8);
```

The REMAP_TABLESPACE parameter is also additive. If you specify the following, then tablespaces TBS1 and TBS3 are changed to TBS2 and TBS4, respectively.

```
SET_REMAP_PARAM(tr_handle,'REMAP_TABLESPACE','TBS1','TBS2');
SET_REMAP_PARAM(tr_handle,'REMAP_TABLESPACE','TBS3','TBS4');
```

The order in which the transformations are performed is undefined. For example, if you specify the following, the result is undefined.

```
SET_REMAP_PARAM(tr_handle,'REMAP_TABLESPACE','TBS1','TBS2');
SET_REMAP_PARAM(tr_handle,'REMAP_TABLESPACE','TBS2','TBS3');
```

> **Note:**
>
> The number of remap parameters that can be specified for a MODIFY transform is limited to ten. That is, you can specify up to ten REMAP_DATAFILE parameters, up to ten REMAP_SCHEMA parameters and so on. Additional instances are ignored. To work around this, you can perform another DBMS_METADATA.ADD_TRANSFORM and specify additional remap parameters.

The GET_DDL, GET_DEPENDENT_DDL, and GET_GRANTED_DDL functions allow the casual browser to extract the creation DDL for an object. So that you can specify transform parameters, this package defines an enumerated constant SESSION_TRANSFORM as the handle of the DDL transform at the session level. You can call SET_TRANSFORM_PARAM using DBMS_METADATA.SESSION_TRANSFORM as the transform handle to set transform parameters for the whole session. GET_DDL, GET_DEPENDENT_DDL, and GET GRANTED_DDL inherit these parameters when they invoke the DDL transform.

> **Note:**
>
> The enumerated constant must be prefixed with the package name `DBMS_METADATA.SESSION_TRANSFORM`.

113
DBMS_METADATA_DIFF

The DBMS_METADATA_DIFF package contains the interfaces for comparing two metadata documents in SXML format.

This chapter contains the following topics:

- Overview
- Security Model
- Browsing APIs for Fetching and Comparing Objects
- Summary of DBMS_METADATA_DIFF Subprograms

> **See Also:**
>
> *Oracle Database Utilities* for more information and for examples of using the DBMS_METADATA_DIFF package.

113.1 DBMS_METADATA_DIFF Overview

You can use the interfaces contained in the DBMS_METADATA_DIFF package to compare two metadata documents in SXML format.

The result of the comparison is an SXML difference document. This document can be converted to other formats using the DBMS_METADATA submit interface and the CONVERT API.

113.2 DBMS_METADATA_DIFF Security Model

The browsing interface of the DBMS_METADATA_DIFF package actually uses the DBMS_METADATA package to fetch the metadata to be compared. Therefore, the security model used for DBMS_METADATA also applies to DBMS_METADATA_DIFF. (Note, however, that DBMS_METADATA_DIFF does not support all object types.)

> **See Also:**
>
> DBMS_METADATA for information about the DBMS_METADATA security model

113.3 DBMS_METADATA_DIFF — Browsing APIs for Fetching and Comparing Objects

These functions allow you to compare the metadata for two objects with a single call.

Syntax

```
DBMS_METADATA_DIFF.COMPARE_SXML(
object_type   IN VARCHAR2,
name1         IN VARCHAR2,
name2         IN VARCHAR2,
schema1       IN VARCHAR2 DEFAULT NULL,
schema2       IN VARCHAR2 DEFAULT NULL,
network_link1 IN VARCHAR2 DEFAULT NULL,
network_link2 IN VARCHAR2 DEFAULT NULL)
RETURN CLOB;

DBMS_METADATA_DIFF.COMPARE_ALTER(
object_type   IN VARCHAR2,
name1         IN VARCHAR2,
name2         IN VARCHAR2,
schema1       IN VARCHAR2 DEFAULT NULL,
schema2       IN VARCHAR2 DEFAULT NULL,
network_link1 IN VARCHAR2 DEFAULT NULL,
network_link2 IN VARCHAR2 DEFAULT NULL)
RETURN CLOB;

DBMS_METADATA_DIFF.COMPARE_ALTER_XML(
object_type   IN VARCHAR2,
name1         IN VARCHAR2,
name2         IN VARCHAR2,
schema1       IN VARCHAR2 DEFAULT NULL,
schema2       IN VARCHAR2 DEFAULT NULL,
network_link1 IN VARCHAR2 DEFAULT NULL,
network_link2 IN VARCHAR2 DEFAULT NULL)
RETURN CLOB;
```

Parameters

Table 113-1 COMPARE_xxx Function Parameters

Parameters	Description
object_type	The type of object to be compared. Valid type names are CLUSTER, CONTEXT, DB_LINK, FGA_POLICY, INDEX, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG, QUEUE, QUEUE_TABLE, RLS_CONTEXT, RLS_GROUP, RLS_POLICY, ROLE, SEQUENCE, SYNONYM, TABLE, TABLESPACE, TRIGGER, TYPE, TYPE_SPEC, TYPE_BODY, USER, and VIEW.
name1	The name of the first object in the comparison.
name2	The name of the second object in the comparison.
schema1	The schema of the first object in the comparison. The default is the current user.

Table 113-1 (Cont.) COMPARE_xxx Function Parameters

Parameters	Description
schema2	The schema of the second object in the comparison. The default is the value of schema1.
network_link1	The name of a database link to the database on which the first object resides. If NULL (the default), then the object is assumed to be in the database on which the caller is running.
network_link2	The name of a database link to the database on which the second object resides. The default is the value of network_link1.

Return Values

DBMS_METADATA_DIFF.COMPARE_xxx returns the differences between two objects.

Exceptions

- INVALID_ARGVAL

  A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.

- OBJECT_NOT_FOUND

  The specified object was not found in the database.

Usage Notes

These functions encapsulate calls to both DBMS_METADATA and DBMS_METADATA_DIFF functions and procedures to fetch the metadata for each of the two objects and compare them.

Which function you use depends on the comparison format you want:

- COMPARE_SXML returns an SXML difference document.
- COMPARE_ALTER returns a set of ALTER statements for making the first object like the second object.
- COMPARE_ALTER_XML returns an ALTER_XML document.

113.4 Summary of DBMS_METADATA_DIFF Subprograms

The DBMS_METADATA_DIFF subprograms provide comparison functionality for different object types.

These subprograms are used to:

- Specify the type of objects to be compared
- Specify the SXML documents to be compared
- Show the differences between the compared documents
- Clean up after the comparison

Table 113-2 provides a summary of DBMS_METADATA_DIFF subprograms.

Table 113-2 DBMS_METADATA_DIFF Package Subprograms

Subprogram	Description
OPENC Function	Specifies the type of objects to be compared
ADD_DOCUMENT Procedure	Specifies an SXML document to be compared
FETCH_CLOB Functions and Procedures	Returns a CLOB showing the differences between the two documents specified by ADD_DOCUMENT
CLOSE Procedure	Invalidates the handle returned by OPENC and cleans up associated state

113.4.1 OPENC Function

This function specifies the type of objects to be compared. The return value is an opaque context handle.

Syntax

```
DBMS_METADATA_DIFF.OPENC (
object_type  IN VARCHAR2)
RETURN NUMBER;
```

Parameters

Table 113-3 OPENC Function Parameters

Parameters	Description
object_type	The type of object to be compared. Valid type names are CLUSTER, CONTEXT, DB_LINK, FGA_POLICY, INDEX, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG, QUEUE, QUEUE_TABLE, RLS_CONTEXT, RLS_GROUP, RLS_POLICY, ROLE, SEQUENCE, SYNONYM, TABLE, TABLESPACE, TRIGGER, TYPE, TYPE_SPEC, TYPE_BODY, USER, and VIEW.

Return Values

The opaque handle that is returned is used as input to ADD_DOCUMENT, FETCH_xxx and CLOSE.

Exceptions

- INVALID_ARGVAL

  A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.

113.4.2 ADD_DOCUMENT Procedure

This procedure specifies an SXML document that is to be compared.

Syntax

```
DBMS_METADATA_DIFF.ADD_DOCUMENT(
handle IN NUMBER, document IN sys.XMLType);

DBMS_METADATA_DIFF.ADD_DOCUMENT(
handle IN NUMBER, document IN CLOB);
```

Parameters

Table 113-4 ADD_DOCUMENT Procedure Parameters

Parameter	Description
`handle`	The handle returned from `OPENC`
`document`	A document to be compared. The document must be of the type specified in `OPENC`.

Usage Notes

Because the comparison interface allows you to compare exactly two SXML documents, a program must call `ADD_DOCUMENT` exactly twice for each `OPENC` handle. In the comparison result, the document specified by the first call is document 1, and the document specified by the second call is document 2.

Exceptions

- `INVALID_ARGVAL`

  A `NULL` or invalid value was supplied for an input parameter. The error message text identifies the parameter.

113.4.3 FETCH_CLOB Functions and Procedures

The `FETCH_CLOB` functions and procedures return a CLOB showing the differences between the two documents specified by `ADD_DOCUMENT`.

Syntax

```
DBMS_METADATA_DIFF.FETCH_CLOB(
handle IN NUMBER)
RETURN CLOB;

DBMS_METADATA_DIFF.FETCH_CLOB(

handle IN  NUMBER,
doc    IN  OUT NOCOPY CLOB);

DBMS_METADATA_DIFF.FETCH_CLOB(
handle IN  NUMBER,
doc    IN  OUT NOCOPY CLOB
diffs  OUT BOOLEAN);
```

Parameters

Table 113-5 FETCH_CLOB Subprogram Parameters

Parameter	Description
handle	The handle returned from OPENC.
doc	A CLOB containing the differences between documents 1 and 2.
diffs	TRUE if the documents are different or FALSE if they are identical.

Return Values

The differences between documents 1 and 2.

Exceptions

- INVALID_ARGVAL

  A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.

113.4.4 CLOSE Procedure

This procedure invalidates the handle returned by OPENC and cleans up associated state.

Syntax

```
DBMS_METADATA_DIFF.CLOSE(
handle IN NUMBER);
```

Parameters

Table 113-6 CLOSE Function Parameters

Parameters	Description
handle	The handle returned from OPENC

Exceptions

- INVALID_ARGVAL

  A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.

114
DBMS_MGD_ID_UTL

The DBMS_MGD_ID_UTL package contains various utility functions and procedures.

These consist of the following utility subprograms:

- A logging utility that sets and gets Java and PL/SQL logging levels.
- A proxy utility consisting of two procedures used to set and unset the host and port of the proxy server.
- A metadata utility consisting of functions and procedures used for managing metadata.

> **See Also:**
>
> *Oracle Database Development Guide* for more information.

This chapter describes each of these utility subprograms and contains the following topics:

- Security Model
- Constants
- Exceptions
- Summary of DBMS_MGD_ID_UTL Subprograms

The examples in this chapter assume that the user has run the following set of commands before running the contents of each script:

```
SQL> connect / as sysdba;
Connected.
SQL> create user mgduser identified by password;
SQL> grant connect, resource to mgduser;
SQL> connect mgduser
Enter password: mgduserpassword
Connected.
SQL> set serveroutput on;
```

114.1 DBMS_MGD_ID_UTL Security Model

You must run the catmgd.sql script to load the DBMS_MGD_ID_UTL package and Identity Code Package schema objects in the MGDSYS schema.

DBMS_MGD_ID_UTL is a MGDSYS-owned package. Any DBMS_MGD_ID_UTL subprogram called from an anonymous PL/SQL block is run using the privileges of the current user.

A user must be granted connect and resource roles to use the DBMS_MGD_ID_UTL package and its subprograms.

EXECUTE privilege is granted to PUBLIC for these ADTs: MGD_ID, MGD_ID_COMPONENT, MGD_ID_COMPONENT_VARRAY, and for this package DBMS_MGD_ID_UTL.

SELECT or READ privilege is granted to PUBLIC for these read-only views: MGD_ID_CATEGORY and MGD_ID_SCHEME and for these metadata views: USER_MGD_ID_CATEGORY and USER_MGD_ID_SCHEME, and for table MGD_ID_XML_VALIDATOR, and for sequence MGD$SEQUENCE_CATEGORY.

INSERT, UPDATE and DELETE privilege is granted to PUBLIC for these metadata views: USER_MGD_ID_CATEGORY and USER_MGD_ID_SCHEME.

Public synonyms, by the same name, are created for these ADTs: MGD_ID, MGD_ID_COMPONENT, MGD_ID_COMPONENT_VARRAY and for this package DBMS_MGD_ID_UTL, as well as for these read-only views: MGD_ID_CATEGORY and MGD_ID_SCHEME and for these metadata views: USER_MGD_ID_CATEGORY and USER_MGD_ID_SCHEME, and for table MGD_ID_XML_VALIDATOR.

114.2 DBMS_MGD_ID_UTL Constants

The DBMS_MGD_ID_UTL package defines several constants for specifying parameter values.

These constants are shown in the following tables.

Table 114-1 DBMS_MGD_ID_UTL Constants — Installed Category IDs and Names

Name	Value
EPC_ENCODING_CATEGORY_ID	1
EPC_ENCODING_CATEGORY_NAME	EPC

Table 114-2 DBMS_MGD_ID_UTL Constants — Logging Levels

Name	Value
LOGGING_LEVEL_OFF	0
LOGGING_LEVEL_SEVERE	1
LOGGING_LEVEL_WARNING	2
LOGGING_LEVEL_INFO	3
LOGGING_LEVEL_FINE	4
LOGGING_LEVEL_FINER	5
LOGGING_LEVEL_FINEST	6
LOGGING_LEVEL_ALL	7

114.3 DBMS_MGD_ID_UTL Exceptions

The table in this topic lists the DBMS_MGD_ID_UTL exceptions.

Table 114-3 Exceptions Raised by DBMS_MGD_ID_UTL Package

Name	Error Code	Description
TDTJavaException	-55200	During the tag data translation, a Java exception was raised.
TDTCategoryNotFound	-55201	The specified category was not found.
TDTSchemeNotFound	-55202	During the tag data translation, the specified scheme was not found.
TDTLevelNotFound	-55203	During the tag data translation, the specified level was not found.
TDTOptionNotFound	-55204	During the tag data translation, the specified option was not found.
TDTFieldValidationException	-55205	During the tag data translation, the validation operation failed on a field.
TDTUndefinedField	-55206	During the tag data translation, an undefined field was detected.
TDTRuleEvaluationFailed	-55207	During the tag data translation, the rule evaluation operation failed.
TDTTooManyMatchingLevels	-55208	During the tag data translation, too many matching levels were found.

114.4 Summary of DBMS_MGD_ID_UTL Subprograms

This table describes the utility subprograms in the DBMS_MGD_ID_UTL package.

All the values and names passed to the procedures defined in the DBMS_MGD_ID_UTL package are case insensitive unless otherwise mentioned. To preserve the case, enclose the values with double quotation marks.

Table 114-4 DBMS_MGD_ID_UTL Package Subprograms

Subprogram	Description
ADD_SCHEME Procedure	Adds a tag data translation scheme to an existing category
CREATE_CATEGORY Function	Creates a new category or a new version of a category
EPC_TO_ORACLE_SCHEME Function	Converts the EPCglobal tag data translation (TDT) XML to Oracle tag data translation XML
GET_CATEGORY_ID Function	Returns the category ID given the category name and the category version
GET_COMPONENTS Function	Returns all relevant separated component names separated by semicolon (';') for the specified scheme
GET_ENCODINGS Function	Returns a list of semicolon (';') separated encodings (formats) for the specified scheme

Table 114-4 (Cont.) DBMS_MGD_ID_UTL Package Subprograms

Subprogram	Description
GET_JAVA_LOGGING_LEVEL Function	Returns an integer representing the current Java trace logging level
GET_PLSQL_LOGGING_LEVEL Function	Returns an integer representing the current PL/SQL trace logging level
GET_SCHEME_NAMES Function	Returns a list of semicolon (';') separated scheme names for the specified category
GET_TDT_XML Function	Returns the Oracle tag data translation XML for the specified scheme
GET_VALIDATOR Function	Returns the Oracle Database tag data translation schema
REFRESH_CATEGORY Function	Refreshes the metadata information on the Java stack for the specified category
REMOVE_CATEGORY Procedure	Removes a category including all the related TDT XML if the value of `category_version` parameter is NULL
REMOVE_PROXY Procedure	Unsets the host and port of the proxy server
REMOVE_SCHEME Procedure	Removes a tag data translation scheme from a category
SET_JAVA_LOGGING_LEVEL Procedure	Sets the Java logging level
SET_PLSQL_LOGGING_LEVEL Procedure	Sets the PL/SQL tracing logging level
SET_PROXY Procedure	Sets the host and port of the proxy server for Internet access
VALIDATE_SCHEME Function	Validates the input tag data translation XML against the Oracle tag data translation schema

114.4.1 ADD_SCHEME Procedure

This procedure adds a tag data translation scheme to an existing category.

Syntax

```
DBMS_MGD_ID_UTL.ADD_SCHEME (
   category_id IN  VARCHAR2,
   tdt_xml     IN  CLOB);
```

Parameters

Table 114-5 ADD_SCHEME Procedure Parameters

Parameter	Description
`category_id`	Category ID
`tdt_xml`	Tag data translation XML

Examples

This example performs the following actions:

1. Creates a category.

2. Adds a contractor scheme and an employee scheme to the MGD_SAMPLE_CATEGORY category.
3. Validates the MGD_SAMPLE_CATEGORY scheme.
4. Tests the tag translation of the contractor scheme and the employee scheme.
5. Removes the contractor scheme.
6. Tests the tag translation of the contractor scheme and this returns the expected exception for the removed contractor scheme.
7. Tests the tag translation of the employee scheme and this returns the expected values.
8. Removes the MGD_SAMPLE_CATEGORY category.

114.4.2 CREATE_CATEGORY Function

This function creates a new category or a new version of a category.

Syntax

```
DBMS_MGD_ID_UTL.CREATE_CATEGORY (
   category_name    IN  VARCHAR2,
   category_version IN  VARCHAR2,
   agency           IN  VARCHAR2,
   URI              IN  VARCHAR2)
 RETURN VARCHAR2;
```

Parameters

Table 114-6 CREATE_CATEGORY Function Parameters

Parameter	Description
`category_name`	Name of category
`category_version`	Category version
`agency`	Organization that owns the category. For example, EPCglobal owns the category EPC.
`URI`	URI that provides additional information about the category

Usage Notes

The return value is the category ID.

Examples

See the ADD_SCHEME Procedure for an example of creating the `MGD_SAMPLE_CATEGORY` category.

114.4.3 EPC_TO_ORACLE_SCHEME Function

This function converts the EPCglobal tag data translation (TDT) XML to Oracle Database tag data translation XML.

Syntax

```
DBMS_MGD_ID_UTL.EPC_TO_ORACLE_SCHEME (
   xml_scheme IN CLOB)
 RETURN CLOB;
```

Parameters

Table 114-7 EPC_TO_ORACLE_SCHEME Function Parameters

Parameter	Description
xml_scheme	Name of EPC tag scheme to be converted

Usage Notes

The return value is the contents of the CLOB containing the Oracle Datanase tag data translation XML.

Examples

The following example converts standard EPCglobal Tag Data Translation (TDT) files into Oracle Database TDT files:

```
--Contents of MGD_ID_DOC2.sql
----------------------------
-- EPC_TO_ORACLE_SCHEME   --
----------------------------
call DBMS_MGD_ID_UTL.set_proxy('www-proxy.example.com', '80');

BEGIN
 DBMS_JAVA.set_output(1000000);
 DBMS_OUTPUT.ENABLE(1000000);
 DBMS_MGD_ID_UTL.set_java_logging_level(DBMS_MGD_ID_UTL.LOGGING_LEVEL_SEVERE);
END;
/

```

114.4.4 GET_CATEGORY_ID Function

This function returns the category ID for a given category name and category version.

Syntax

```
DBMS_MGD_ID_UTL.GET_CATEGORY_ID (
   category name     IN  VARCHAR2,
   category_version  IN  VARCHAR2)
 RETURN VARCHAR2;
```

Parameters

Table 114-8 GET_CATEGORY_ID Function Parameters

Parameter	Description
category_name	Name of category
category_version	Category version

Usage Notes

- If the value of category_version is NULL, then the ID of the latest version of the specified category is returned.
- The return value is the category ID for the specified category name.

Examples

The following example returns a category ID given a category name and its version:

```
-- Contents of get_category1.sql file
SELECT DBMS_MGD_ID_UTL.get_category_id('EPC', NULL) FROM DUAL;

SQL> @get_category1.sql
.
.
.
DBMS_MGD_ID_UTL.GET_CATEGORY_ID('EPC',NULL)------------------------------------------------------
-------------------------1
.
.
.
```

114.4.5 GET_COMPONENTS Function

This function returns all relevant separated component names separated by semicolon (;) for the specified scheme.

Syntax

```
DBMS_MGD_ID_UTL.GET_COMPONENTS (
   category_id IN VARCHAR2,
   scheme_name IN VARCHAR2)
 RETURN VARCHAR2;
```

Parameters

Table 114-9 GET_COMPONENTS Function Parameters

Parameter	Description
category_id	Category ID
scheme_name	Name of scheme

Usage Notes

The return value contains the component names separated by a semicolon (;) for the specified scheme.

Examples

The following example gets the components:

```
--Contents of get_components.sql
DECLARE
  id             mgd_id;
  getcomps       VARCHAR2(1000);
  getencodings   VARCHAR2(1000);
  getschemenames VARCHAR2(1000);
BEGIN
 DBMS_MGD_ID_UTL.set_java_logging_level(DBMS_MGD_ID_UTL.LOGGING_LEVEL_OFF);
 DBMS_MGD_ID_UTL.refresh_category(DBMS_MGD_ID_UTL.get_category_id('EPC', NULL));
 getcomps := DBMS_MGD_ID_UTL.get_components(1,'SGTIN-64');
 dbms_output.put_line('Component names are: ' || getcomps);
 getencodings := DBMS_MGD_ID_UTL.get_encodings(1,'SGTIN-64');
 dbms_output.put_line('Encodings are: ' || getencodings);
 getschemenames := DBMS_MGD_ID_UTL.get_scheme_names(1);
 dbms_output.put_line('Scheme names are: ' || getschemenames);
END;
/
SHOW ERRORS;

SQL> @get_components.sql
.
.
.
Component names are:
filter,gtin,companyprefixlength,companyprefix,companyprefixindex,itemref,serial
Encodings are: ONS_HOSTNAME,LEGACY,TAG_ENCODING,PURE_IDENTITY,BINARY
Scheme names are:
GIAI-64,GIAI-96,GID-96,GRAI-64,GRAI-96,SGLN-64,SGLN-96,SGTIN-64,SGTIN-96,SSCC-64
,SSCC-96,USDOD-64,USDOD-96
PL/SQL procedure successfully completed.
.
.
.
```

114.4.6 GET_ENCODINGS Function

This function returns a list of semicolon (;) separated encodings (formats) for the specified scheme.

Syntax

```
DBMS_MGD_ID_UTL.GET_ENCODINGS (
   category_id IN VARCHAR2,
   scheme_name IN VARCHAR2)
 RETURN VARCHAR2;
```

Parameters

Table 114-10 GET_ENCODINGS Function Parameters

Parameter	Description
category_id	Category ID
scheme_name	Name of scheme

Usage Notes

The return value contains the encodings separated by a semicolon (;) for the specified scheme.

Examples

See the GET_COMPONENTS Function for an example.

114.4.7 GET_JAVA_LOGGING_LEVEL Function

This function returns an integer representing the current trace logging level.

Syntax

```
DBMS_MGD_ID_UTL.GET_JAVA_LOGGING_LEVEL
 RETURN INTEGER;
```

Usage Notes

The return value is the integer value denoting the current Java logging level.

Examples

The following example gets the Java logging level.

```
--Contents of getjavalogginglevel.sql
DECLARE
     loglevel   NUMBER;
BEGIN
  DBMS_MGD_ID_UTL.set_java_logging_level(DBMS_MGD_ID_UTL.LOGGING_LEVEL_OFF);
  loglevel := DBMS_MGD_ID_UTL.get_java_logging_level();
  dbms_output.put_line('Java logging level = ' ||loglevel);
END;
/
SHOW ERRORS;

SQL> @getjavalogginglevel.sql
.
.
.
Java logging level = 0
PL/SQL procedure successfully completed.
.
.
.
```

114.4.8 GET_PLSQL_LOGGING_LEVEL Function

This function returns an integer representing the current PL/SQL trace logging level.

Syntax

```
DBMS_MGD_ID_UTL.GET_PLSQL_LOGGING_LEVEL
 RETURN INTEGER;

PRAGMA restrict_references(get_plsql_logging_level, WNDS);
```

Usage Notes

The return value is the integer value denoting the current PL/SQL logging level.

Examples

The following example gets the PL/SQL logging level.

```
--Contents of getplsqlloggінglevel.sql
DECLARE
     loglevel   NUMBER;
BEGIN
  DBMS_MGD_ID_UTL.set_plsql_logging_level(0);
  loglevel := DBMS_MGD_ID_UTL.get_plsql_logging_level();
  dbms_output.put_line('PL/SQL logging level = ' ||loglevel);
END;
/
SHOW ERRORS;

SQL> @getplsqlloggінglevel.sql
.
.
.
PL/SQL logging level = 0
PL/SQL procedure successfully completed.
.
.
.
```

114.4.9 GET_SCHEME_NAMES Function

This function returns a list of semicolon (;) separated scheme names for the specified category.

Syntax

```
DBMS_MGD_ID_UTL.GET_SCHEME_NAMES (
   category_id IN VARCHAR2)
 RETURN VARCHAR2;
```

Parameters

Table 114-11 GET_SCHEME_NAMES Function Parameters

Parameter	Description
category_id	Category ID

Usage Notes

The return value contains the scheme names for the specified category ID.

Examples

See the GET_COMPONENTS Function for an example.

114.4.10 GET_TDT_XML Function

This function returns the Oracle Database tag data translation XML for the specified scheme.

Syntax

```
DBMS_MGD_ID_UTL.GET_TDT_XML (
   category_id  IN VARCHAR2,
   scheme_name  IN VARCHAR2)
 RETURN CLOB;
```

Parameters

Table 114-12 GET_TDT_XML Function Parameters

Parameter	Description
category_id	Category ID
scheme_name	Name of scheme

Usage Notes

The return value contains the Oracle Database tag data translation XML for the specified scheme.

Examples

The following example gets the Oracle Database TDT XML for the specified scheme:

```
--Contents of get_tdtxml.sql
DECLARE
  gettdtxml      CLOB;

BEGIN
  gettdtxml := DBMS_MGD_ID_UTL.get_tdt_xml(1,'SGTIN-64');
  dbms_output.put_line('Length of tdt XML is '||DBMS_LOB.GETLENGTH(gettdtxml));
  dbms_output.put_line(DBMS_LOB.SUBSTR(gettdtxml, DBMS_LOB.GETLENGTH(gettdtxml), 1));
END;
/
```

```

114.4.11 GET_VALIDATOR Function

This function returns the Oracle Database tag data translation schema.

Syntax

```
DBMS_MGD_ID_UTL.GET_VALIDATOR
 RETURN CLOB;
```

Usage Notes

The return value contains the Oracle Database tag data translation schema.

Examples

This example returns the Oracle Database TDT schema.

```
--Contents of get_validator.sql
DECLARE
  getvalidator              CLOB;
BEGIN
  getvalidator := DBMS_MGD_ID_UTL.get_validator;
  dbms_output.put_line('Length of validated oracle scheme xml is '||

114.4.12 REFRESH_CATEGORY Function

This function refreshes the metadata information on the Java stack for the specified category.

This function must be called before using `MGD_ID` functions.

Syntax

```
DBMS_MGD_ID_UTL.REFRESH_CATEGORY (
   category_id  IN VARCHAR2);
```

Parameters

Table 114-13 REFRESH_CATEGORY Function Parameters

Parameter	Description
`category_id`	Category ID

Examples

The following example refreshes the metadata information for the EPC category ID.

```
--Contents of tostring3.sql
call DBMS_MGD_ID_UTL.set_proxy('www-proxy.example.com', '80');
DECLARE
id          MGD_ID;
BEGIN
 DBMS_MGD_ID_UTL.set_java_logging_level(DBMS_MGD_ID_UTL.LOGGING_LEVEL_OFF);
 DBMS_MGD_ID_UTL.refresh_category(DBMS_MGD_ID_UTL.get_category_id('EPC', NULL));
 dbms_output.put_line('..Testing to_string');
 DBMS_OUTPUT.PUT_LINE('test to_string');
   id := mgd_id('EPC', NULL, 'urn:epc:id:gid:0037000.30241.1041970',
'scheme=GID-96');
      DBMS_OUTPUT.PUT_LINE('mgd_id object as a string');
      DBMS_OUTPUT.PUT_LINE(id.to_string);
END;
/
SHOW ERRORS;
call DBMS_MGD_ID_UTL.remove_proxy();

SQL> @tostring3.sql
..Testing to_string
test to_string
mgd_id object as a string
category_id =1;schemes = GID-96;objectclass = 30241;generalmanager =
0037000;scheme = GID-96;1 = 1;serial = 1041970

PL/SQL procedure successfully completed.
```

114.4.13 REMOVE_CATEGORY Procedure

This procedure removes a category including all the related TDT XML.

This procedure is overloaded. The different functionality of each form of syntax is presented along with the definitions.

Syntax

Removes a category based on the specified category ID.

```
DBMS_MGD_ID_UTL.REMOVE_CATEGORY (
   category_id  IN VARCHAR2);
```

Removes a category based on the specified category name and category version.

```
DBMS_MGD_ID_UTL.REMOVE_CATEGORY (
   category_name    IN VARCHAR2,
   category_version IN VARCHAR2);
```

Parameters

Table 114-14 REMOVE_CATEGORY Procedure Parameters

Parameter	Description
category_id	Category ID

Table 114-14 (Cont.) REMOVE_CATEGORY Procedure Parameters

Parameter	Description
`category_name`	Name of category
`category_version`	Category version

Usage Notes

If the value of `category_version` is NULL, all versions for the specified category will be removed.

Examples

See the ADD_SCHEME Procedure for an example of removing a category.

114.4.14 REMOVE_PROXY Procedure

This procedure unsets the host and port of the proxy server.

Syntax

```
DBMS_MGD_ID_UTL.REMOVE_PROXY;
```

Examples

See the REFRESH_CATEGORY Function for an example.

114.4.15 REMOVE_SCHEME Procedure

This procedure removes a tag data translation scheme from a category.

Syntax

```
DBMS_MGD_ID_UTL.REMOVE_SCHEME (
   category_id  IN  VARCHAR2,
   scheme_name  IN  VARCHAR2);
```

Parameters

Table 114-15 REMOVE_SCHEME Procedure Parameters

Parameter	Description
`category_id`	Category ID
`scheme_name`	Name of scheme

Examples

See the ADD_SCHEME Procedure for an example of removing a scheme.

114.4.16 SET_JAVA_LOGGING_LEVEL Procedure

This procedure sets the Java trace logging level.

Syntax

```
DBMS_MGD_ID_UTL.SET_JAVA_LOGGING_LEVEL (
   logginglevel IN  INTEGER);
```

Parameters

Table 114-16 SET_JAVA_LOGGING_LEVEL Procedure Parameters

Parameter	Description
`logginglevel`	Logging level. The Java logging level can be one of the following values in descending order: • `LOGGING_LEVEL_OFF CONSTANT INTEGER := 0` • `LOGGING_LEVEL_SEVERE CONSTANT INTEGER := 1` • `LOGGING_LEVEL_WARNING CONSTANT INTEGER := 2` • `LOGGING_LEVEL_INFO CONSTANT INTEGER := 3` • `LOGGING_LEVEL_FINE CONSTANT INTEGER := 4` • `LOGGING_LEVEL_FINER CONSTANT INTEGER := 5` • `LOGGING_LEVEL_FINEST CONSTANT INTEGER := 6` • `LOGGING_LEVEL_ALL CONSTANT INTEGER := 7`

Examples

See the GET_JAVA_LOGGING_LEVEL Function for an example.

114.4.17 SET_PLSQL_LOGGING_LEVEL Procedure

This procedure sets the PL/SQL trace logging level.

Syntax

```
DBMS_MGD_ID_UTL.SET_PLSQL_LOGGING_LEVEL (
   level IN INTEGER);

PRAGMA restrict_references(set_plsql_logging_level, WNDS);
```

Parameters

Table 114-17 SET_PLSQL_LOGGING_LEVEL Procedure Parameters

Parameter	Description
`level`	Logging level. The PL/SQL logging level can be one of the following values in descending order: • `LOGGING_LEVEL_OFF CONSTANT INTEGER := 0` • `LOGGING_LEVEL_SEVERE CONSTANT INTEGER := 1` • `LOGGING_LEVEL_WARNING CONSTANT INTEGER := 2` • `LOGGING_LEVEL_INFO CONSTANT INTEGER := 3` • `LOGGING_LEVEL_FINE CONSTANT INTEGER := 4` • `LOGGING_LEVEL_FINER CONSTANT INTEGER := 5` • `LOGGING_LEVEL_FINEST CONSTANT INTEGER := 6` • `LOGGING_LEVEL_ALL CONSTANT INTEGER := 7`

Examples

See the GET_PLSQL_LOGGING_LEVEL Function for an example.

114.4.18 SET_PROXY Procedure

This procedure sets the host and port of the proxy server for Internet access.

This procedure must be called if the database server accesses the Internet using a proxy server. Internet access is necessary because some rules need to look up the Object Naming Service (ONS) table to get the company prefix index.

You do not need to call this procedure does if you are only using schemes that do not contain any rules requiring Internet access.

Syntax

```
DBMS_MGD_ID_UTL.SET_PROXY (
   proxt_host   IN  VARCHAR2,
   proxy_port   IN  VARCHAR2);
```

Parameters

Table 114-18 SET_PROXY Procedure Parameters

Parameter	Description
`proxy_host`	Name of host
`proxy_port`	Host port number

Examples

See the REFRESH_CATEGORY Function for an example.

114.4.19 VALIDATE_SCHEME Function

This function validates the input tag data translation XML against the Oracle Database tag data translation schema.

Syntax

```
DBMS_MGD_ID_UTL.VALIDATE_SCHEME (
   xml_scheme IN CLOB)
 RETURN VARCHAR2;
```

Parameters

Table 114-19 VALIDATE_SCHEME Function Parameters

Parameter	Description
xml_scheme	Scheme to be validated.

Usage Notes

The return value contains the components names for the specified scheme.

Examples

See the ADD_SCHEME Procedure or the EPC_TO_ORACLE_SCHEME Function for an example.

115
DBMS_MGWADM

DBMS_MGWADM defines the Messaging Gateway administrative interface. The package and object types are owned by SYS.

> **Note:**
>
> You must run the catmgw.sql script to load the Messaging Gateway packages and types into the database.

> **See Also:**
>
> *Oracle Database Advanced Queuing User's Guide* contains information on loading database objects and using DBMS_MGWADM

This chapter contains the following topics:

- Security Model
- Deprecated Subprograms
- Constants
- Data Structures
- Summary of DBMS_MGWADM Subprograms

115.1 DBMS_MGWADM Security Model

A user with administrative privilege can run all procedures in DBMS_MGWADM.

115.2 DBMS_MGWADM Deprecated Subprograms

Oracle recommends that you do not use deprecated procedures in new applications. Support for deprecated features is for backward compatibility only.

The following subprograms are deprecated with Oracle Database 11*g* Release 1 having been superseded by improved technology:

- ADD_SUBSCRIBER Procedure - use instead CREATE_JOB Procedure
- ALTER_PROPAGATION_SCHEDULE Procedure - use instead ALTER_JOB Procedure
- ALTER_SUBSCRIBER Procedure - use instead ALTER_JOB Procedure
- DB_CONNECT_INFO Procedure - use instead ALTER_AGENT Procedures

- DISABLE_PROPAGATION_SCHEDULE Procedure - use instead DISABLE_JOB Procedure
- ENABLE_PROPAGATION_SCHEDULE Procedure - use instead ENABLE_JOB Procedure
- REMOVE_SUBSCRIBER Procedure - use instead REMOVE_JOB Procedure
- RESET_SUBSCRIBER Procedure - use instead RESET_JOB Procedure
- SCHEDULE_PROPAGATION Procedure - use instead CREATE_JOB Procedure
- UNSCHEDULE_PROPAGATION Procedure - use instead REMOVE_JOB Procedure

115.3 DBMS_MGWADM Constants

The DBMS_MGWADM package defines various constants for specifying parameter values.

- Table 115-1
- Table 115-2
- Table 115-3
- Table 115-4
- Table 115-5
- Table 115-6
- Table 115-7
- Table 115-8
- Table 115-9
- Table 115-10
- Table 115-11

Table 115-1 DBMS_MGWADM Constants—Cleanup Actions

Name	Type	Description
CLEAN_STARTUP_STATE	CONSTANT BINARY_INTEGER	Sets the Messaging Gateway agent to a known state so that it can be started
CLEAN_LOG_QUEUES	CONSTANT BINARY_INTEGER	Messaging Gateway agent will clean log queues for all configured messaging system links
RESET_SUB_MISSING_LOG_REC	CONSTANT BINARY_INTEGER	Messaging Gateway agent recovers a Messaging Gateway subscriber that has failed due to a missing log record
RESET_SUB_MISSING_MESSAGE	CONSTANT BINARY_INTEGER	Messaging Gateway agent recovers a Messaging Gateway subscriber that has failed due to a missing persistent source message

Table 115-2 DBMS_MGWADM Constants—Force Values

Name	Type	Description
FORCE	CONSTANT BINARY_INTEGER	Represents a forced action
NO_FORCE	CONSTANT BINARY_INTEGER	Represents a normal, nonforced action

Table 115-3 DBMS_MGWADM Constants—Logging Levels

Name	Type	Description
BASIC_LOGGING	CONSTANT BINARY_INTEGER	The standard (the least) information written to the log file
TRACE_DEBUG_LOGGING	CONSTANT BINARY_INTEGER	The greatest information written to the log file
TRACE_HIGH_LOGGING	CONSTANT BINARY_INTEGER	The third level of detail of logging information written to the log file
TRACE_LITE_LOGGING	CONSTANT BINARY_INTEGER	The second level detail of logging information written to the log file

Table 115-4 DBMS_MGWADM Constants—Named Property Constants

Name	Type	Description
MGWPROP_PREFIX	CONSTANT VARCHAR2	A constant (MGWPROP$_) for the reserved property name prefix
MGWPROP_REMOVE	CONSTANT VARCHAR2	A constant (MGWPROP$_REMOVE) for the reserved property name used to remove an existing property
MGWPROP_REMOVE_ALL	CONSTANT VARCHAR2	A constant (MGWPROP$_REMOVE_ALL) for the reserved property name used to remove all properties

Table 115-5 DBMS_MGWADM Constants—Other Constants

Name	Type	Description
JMS_CONNECTION	CONSTANT BINARY_INTEGER	Used to indicate that JMS connections will be used to access JMS destinations in a domain-independent manner that supports a unified messaging model
JMS_QUEUE_CONNECTION	CONSTANT BINARY_INTEGER	Used to indicate that JMS queue connections will be used to access JMS destinations
JMS_TOPIC_CONNECTION	CONSTANT BINARY_INTEGER	Used to indicate that JMS topic connections will be used to access JMS destinations
NO_CHANGE	CONSTANT VARCHAR2	Indicates that an existing value should be preserved (not changed). This is used for certain APIs where the desire is to change one or more parameters but leave others unchanged.

Table 115-5 (Cont.) DBMS_MGWADM Constants—Other Constants

Name	Type	Description
DEFAULT_AGENT	CONSTANT VARCHAR2	Name of the Messaging Gateway default agent

Table 115-6 DBMS_MGWADM Constants—Propagation Types

Name	Type	Description
INBOUND_PROPAGATION	CONSTANT BINARY_INTEGER	Represents the propagation type for non-Oracle to Oracle Database Advanced Queuing propagation. The propagation source is a queue in a foreign (non-Oracle) messaging system and the destination is a local Oracle Database Advanced Queuing queue.
OUTBOUND_PROPAGATION	CONSTANT BINARY_INTEGER	Represents the propagation type for Oracle Database Advanced Queuing to non-Oracle propagation. The propagation source is a local Oracle Database Advanced Queuing queue and the destination is a queue in a foreign (non-Oracle) messaging system.

Table 115-7 DBMS_MGWADM Constants—Queue Domain Types

Name	Type	Description
DOMAIN_QUEUE	CONSTANT BINARY_INTEGER	Represents a queue destination. A JMS queue (point-to-point model) is classified as a queue.
DOMAIN_TOPIC	CONSTANT BINARY_INTEGER	Represents a topic destination. A JMS topic (publish-subscribe model) is classified as a topic.

Table 115-8 DBMS_MGWADM Constants—Shutdown Modes

Name	Type	Description
SHUTDOWN_IMMEDIATE	CONSTANT BINARY_INTEGER	Represents the immediate shutdown mode
SHUTDOWN_NORMAL	CONSTANT BINARY_INTEGER	Represents the normal shutdown mode

Table 115-9 DBMS_MGWADM Constants—WebSphere MQ Interface Types

Name	Type	Description
MQSERIES_BASE_JAVA_INTERFACE	CONSTANT BINARY_INTEGER	Represents the Base Java interface for the WebSphere MQ messaging system

Table 115-10 DBMS_MGWADM Constants—target_type Argument of SET_OPTION and REMOVE_OPTION Procedures

Name	Type	Description
AGENT_JAVA_PROP	CONSTANT PLS_INTEGER	Used for an agent option used to set a Java System property
MSGLINK_OPTION	CONSTANT PLS_INTEGER	Used for a messaging system link option
JOB_OPTION	CONSTANT PLS_INTEGER	Used for a propagation job option

Table 115-11 DBMS_MGWADM Constants—conntype Argument of CREATE_AGENT and ALTER_AGENT Procedures

Name	Type	Description
JDBC_OCI	CONSTANT VARCHAR2	Used to specify the JDBC OCI driver
JDBC_THIN	CONSTANT VARCHAR2	Used to specify the JDBC Thin driver

115.4 DBMS_MGWADM Data Structures

The DBMS_MGWADM package defines several OBJECT types.

DBMS_MGWADM Object Types

- SYS.MGW_MQSERIES_PROPERTIES Object Type
- SYS.MGW_PROPERTIES Object Type
- SYS.MGW_PROPERTY Object Type
- SYS.MGW_TIBRV_PROPERTIES Object Type

115.4.1 DBMS_MGWADM SYS.MGW_MQSERIES_PROPERTIES Object Type

This type specifies basic properties for a WebSphere MQ messaging system link.

Syntax

```
TYPE SYS.MGW_MQSERIES_PROPERTIES IS OBJECT (
   queue_manager       VARCHAR2(64),
   hostname            VARCHAR2(64),
   port                INTEGER,
   channel             VARCHAR2(64),
   interface_type      INTEGER,
   username            VARCHAR2(64),
   password            VARCHAR2(64),
   inbound_log_queue   VARCHAR2(64),
   outbound_log_queue  VARCHAR2(64),

-- Methods
STATIC FUNCTION construct
RETURN SYS.MGW_MQSERIES_PROPERTIES,
```

```
STATIC FUNCTION alter_construct
RETURN SYS.MGW_MQSERIES_PROPERTIES );
```

Attributes

Table 115-12 SYS.MGW_MQSERIES_PROPERTIES Attributes

Attribute	Description
queue_manager	The name of the WebSphere MQ queue manager
hostname	The host on which the WebSphere MQ messaging system resides. If hostname is NULL, then a WebSphere MQ bindings connection is used. If not NULL, then a client connection is used and requires that a port and channel be specified.
port	The port number. This is used only for client connections; that is, when hostname is not NULL.
channel	The channel used when establishing a connection to the queue manager. This is used only for client connections; that is, when hostname is not NULL.
interface_type	The type of messaging interface to use. Values: • DBMS_MGWADM.MQSERIES_BASE_JAVA_INTERFACE if the WebSphere MQ Base Java interface should be used. • DBMS_MGWADM.JMS_CONNECTION if the link is to be used to access JMS destinations in a unified, domain-independent manner. • DBMS_MGWADM.JMS_QUEUE_CONNECTION if the link is to be used for accessing JMS queues • DBMS_MGWADM.JMS_TOPIC_CONNECTION if the link is to be used for accessing JMS topics.
username	The username used for authentication to the WebSphere MQ messaging system
password	The password used for authentication to the WebSphere MQ messaging system
inbound_log_queue	The name of the WebSphere MQ queue used for propagation recovery purposes when this messaging link is used for inbound propagation; that is, when queues associated with this link serve as a propagation source: • For MQSERIES_BASE_JAVA_INTERFACE, this is the name of a physical WebSphere MQ queue created using WebSphere MQ administration tools. • For the JMS_CONNECTION interface and the JMS_QUEUE_CONNECTION interface, this is the name of a physical WebSphere MQ queue created using WebSphere MQ administration tools. • For JMS_TOPIC_CONNECTION interface, this specifies the name of a WebSphere MQ JMS topic. The physical WebSphere MQ queue used by subscribers of that topic must be created using WebSphere MQ administration tools. By default, the physical queue used is SYSTEM.JMS.D.SUBSCRIBER.QUEUE.

Table 115-12 (Cont.) SYS.MGW_MQSERIES_PROPERTIES Attributes

Attribute	Description
outbound_log_queue	The name of the WebSphere MQ queue used for propagation recovery purposes when this messaging link is used for outbound propagation; that is, when queues associated with this link serve as a propagation destination: • For MQSERIES_BASE_JAVA_INTERFACE, this is the name of a physical WebSphere MQ queue created using WebSphere MQ administration tools. • For the JMS_CONNECTION interface and the JMS_QUEUE_CONNECTION interface, this is the name of a physical WebSphere MQ queue created using WebSphere MQ administration tools. • For JMS_TOPIC_CONNECTION interface, this specifies the name of a WebSphere MQ JMS topic. The physical WebSphere MQ queue used by subscribers of that topic must be created using WebSphere MQ administration tools. By default, the physical queue used is SYSTEM.JMS.D.SUBSCRIBER.QUEUE.

Methods

Table 115-13 SYS.MGW_MQSERIES_PROPERTIES Methods

Method	Description
construct	Constructs a new SYS.MGW_MQSERIES_PROPERTIES instance. All attributes are assigned a value of NULL
alter_construct	Constructs a new SYS.MGW_MQSERIES_PROPERTIES instance for altering the properties of an existing messaging link. All attributes having a VARCHAR2 datatype are assigned a value of DBMS_MGWADM.NO_CHANGE. Attributes of other datatypes are assigned a value of NULL.

115.4.2 DBMS_MGWADM SYS.MGW_PROPERTIES Object Type

This type specifies an array of properties.

Syntax

```
TYPE SYS.MGW_PROPERTIES AS VARRAY (2000) OF SYS.MGW_PROPERTY;
```

Attributes

Table 115-14 SYS.MGW_PROPERTIES Attributes

Attribute	Description
name	Property name
value	Property value

Usage Notes

Unless noted otherwise, Messaging Gateway uses named properties as follows:

- Names with the `MGWPROP$_` prefix are reserved. They are used for special purposes and are invalid when used as a normal property name.
- A property name can exist only once in a property list; that is, a list can contain only one value for a given name. The name is case-insensitive.
- In general, a property list is order-independent, and the property names may appear in any order. An alter property list is an exception.
- You can use a new property list to alter an existing property list. Each new property modifies the original list in one of the following ways: adds a new property, modifies a property, removes a property, or removes all properties.

The alter list is processed in order, from the first element to the last element. Thus the order in which the elements appear in the alter list is meaningful, especially when the alter list is used to remove properties from an existing list.

The property name and value are used to determine how that element affects the original list. The following rules apply:

- Add or modify property

  ```
  MGW_PROPERTY.NAME = property_name
  MGW_PROPERTY.VALUE = property_value
  ```

  If a property of the given name already exists, then the current value is replaced with the new value; otherwise the new property is added to the end of the list.

- Remove property

  ```
  MGW_PROPERTY.NAME = 'MGWPROP$_REMOVE'
  MGW_PROPERTY.VALUE = name_of_property_to_remove
  ```

  No action is taken if the property name does not exist in the original list.

- Remove all properties

  ```
  MGW_PROPERTY.NAME = 'MGWPROP$_REMOVE_ALL'
  MGW_PROPERTY.VALUE = not used
  ```

> **See Also:**
>
> "The `DBMS_MGWADM` package defines constants to represent the reserved property names on Table 115-4

115.4.3 DBMS_MGWADM SYS.MGW_PROPERTY Object Type

This type specifies a named property which is used to specify optional properties for messaging links, foreign queues, and subscribers.

Syntax

```
TYPE SYS.MGW_PROPERTY IS OBJECT(
   name  VARCHAR2(500),
```

```
   value VARCHAR2(4000),

-- Methods
STATIC FUNCTION construct    --- (1)
RETURN SYS.MGW_PROPERTY,

STATIC FUNCTION construct(   --- (2)
   p_name   IN VARCHAR2,
   p_value  IN VARCHAR2)
RETURN SYS.MGW_PROPERTY );
```

Attributes

Table 115-15 SYS.MGW_PROPERTY Attributes

Attribute	Description
`name`	Property name
`value`	Property value

Methods

Table 115-16 SYS.MGW_PROPERTY Methods

Method	Description
`construct --- (1)`	Constructs a new `MGW_PROPERTY` instance. All attributes are assigned a value of `NULL`
`construct --- (2)`	Constructs a new `MGW_PROPERTY` instance initialized using the given parameters

> **See Also:**
>
> "The `DBMS_MGWADM` package defines constants to represent the reserved property names on Table 115-4

115.4.4 SYS.MGW_TIBRV_PROPERTIES Object Type

A type that specifies basic properties for a TIB/Rendezvous messaging system link. The Messaging Gateway agent creates a TIB/Rendezvous transport of type `TibrvRvdTransport` for each Messaging Gateway link.

Syntax

```
TYPE SYS.MGW_TIBRV_PROPERTIES IS OBJECT(
   service   VARCHAR2(128),
   daemon    VARCHAR2(128),
   network   VARCHAR2(256),
   cm_name   VARCHAR2(256),
   cm_ledger VARCHAR2(256),

-- Methods
STATIC FUNCTION construct
```

```
RETURN SYS.MGW_TIBRV_PROPERTIES,

STATIC FUNCTION alter_construct
RETURN SYS.MGW_TIBRV_PROPERTIES );
```

Attributes

Table 115-17 SYS.MGW_TIBRV_PROPERTIES Attributes

Attribute	Description
service	The service parameter for the rvd transport
daemon	The daemon parameter for the rvd transport
network	The network parameter for the rvd transport
cm_name	The CM correspondent name. Reserved for future use.
cm_ledger	The CM ledger file name. Reserved for future use.

Methods

Table 115-18 SYS.MGW_TIBRV_PROPERTIES Methods

Method	Description
construct	Constructs a new SYS.MGW_TIBRV_PROPERTIES instance. All attributes will be assigned a value of NULL.
alter_construct	Constructs a new SYS.MGW_TIBRV_PROPERTIES instance. This function is useful for altering the properties of an existing messaging link. All attributes having a VARCHAR2 datatype will be assigned a value of DBMS_MGWADM.NO_CHANGE. Attributes of other datatypes will be assigned a value of NULL.

115.5 Summary of DBMS_MGWADM Subprograms

This table lists the DBMS_MGWADM subprograms and briefly describes them.

Table 115-19 DBMS_MGWADM Package Subprograms

Subprogram	Description
ADD_SUBSCRIBER Procedure	Adds a subscriber used to consume messages from a source queue for propagation to a destination
ALTER_AGENT Procedures	Alters Messaging Gateway agent parameters
ALTER_JOB Procedure	Alters the properties of a propagation job
ALTER_MSGSYSTEM_LINK Procedure for TIB/Rendezvous	Alters the properties of a TIB/Rendezvous messaging system link
ALTER_MSGSYSTEM_LINK Procedure for WebSphere MQ	Alters the properties of a WebSphere MQ messaging system link
ALTER_PROPAGATION_SCHEDULE Procedure	Alters a propagation schedule

Table 115-19 (Cont.) DBMS_MGWADM Package Subprograms

Subprogram	Description
ALTER_SUBSCRIBER Procedure	Alters the parameters of a subscriber used to consume messages from a source queue for propagation to a destination
CLEANUP_GATEWAY Procedures	Cleans up Messaging Gateway
CREATE_AGENT Procedure	Creates a Messaging Gateway agent that will be used to process propagation jobs
CREATE_JOB Procedure	Creates a job used to propagate message from a source to a destination
CREATE_MSGSYSTEM_LINK Procedures for TIB/Rendezvous	Creates a messaging system link to a TIB/Rendezvous messaging system
CREATE_MSGSYSTEM_LINK Procedures for WebSphere MQ	Creates a messaging system link to a WebSphere MQ messaging system
DB_CONNECT_INFO Procedure	Configures connection information used by the Messaging Gateway agent for connections to Oracle Database
DISABLE_JOB Procedure	Disables a propagation job
DISABLE_PROPAGATION_SCHEDULE Procedure	Disables a propagation schedule
ENABLE_JOB Procedure	Enables a propagation job
ENABLE_PROPAGATION_SCHEDULE Procedure	Enables a propagation schedule
REGISTER_FOREIGN_QUEUE Procedure	Registers a non-Oracle queue entity in Messaging Gateway
REMOVE_AGENT Procedure	Removes a Messaging Gateway agent
REMOVE_JOB Procedure	Removes a propagation job
REMOVE_MSGSYSTEM_LINK Procedure	Removes a messaging system link for a non-Oracle messaging system
REMOVE_OPTION Procedure	Removes a Messaging Gateway configuration option
REMOVE_SUBSCRIBER Procedure	Removes a subscriber used to consume messages from a source queue for propagation to a destination
RESET_JOB Procedure	Resets the propagation error state for a propagation job
RESET_SUBSCRIBER Procedure	Resets the propagation error state for a subscriber
SCHEDULE_PROPAGATION Procedure	Schedules message propagation from a source to a destination
SET_LOG_LEVEL Procedures	Dynamically alters the Messaging Gateway agent logging level
SET_OPTION Procedure	Sets a Messaging Gateway configuration option
SHUTDOWN Procedures	Shuts down the Messaging Gateway agent
STARTUP Procedures	Starts the Messaging Gateway agent
UNREGISTER_FOREIGN_QUEUE Procedure	Removes a non-Oracle queue entity in Messaging Gateway
UNSCHEDULE_PROPAGATION Procedure	Removes a propagation schedule

115.5.1 ADD_SUBSCRIBER Procedure

This procedure adds a subscriber used to consume messages from a source queue for propagation to a destination.

> **Note:**
>
> This subprogram has been deprecated as a result of improved technology (see CREATE_JOB Procedure), and is retained only for reasons of backward compatibility.

Syntax

```
DBMS_MGWADM.ADD_SUBSCRIBER(
   subscriber_id     IN VARCHAR2,
   propagation_type  IN BINARY_INTEGER,
   queue_name        IN VARCHAR2,
   destination       IN VARCHAR2,
   rule              IN VARCHAR2 DEFAULT NULL,
   transformation    IN VARCHAR2 DEFAULT NULL,
   exception_queue   IN VARCHAR2 DEFAULT NULL
   options           IN SYS.MGW_PROPERTIES DEFAULT NULL);
```

Parameters

Table 115-20 ADD_SUBSCRIBER Procedure Parameters

Parameter	Description
`subscriber_id`	Specifies a user-defined name that identifies this subscriber
`propagation_type`	Specifies the type of message propagation. `DBMS_MGWADM.OUTBOUND_PROPAGATION` is for Oracle Database Advanced Queuing to non-Oracle propagation. `DBMS_MGWADM.INBOUND_PROPAGATION` is for non-Oracle to Oracle Database Advanced Queuing propagation
`queue_name`	Specifies the source queue to which this subscriber is being added. The syntax and interpretation of this parameter depend on the value specified for `propagation_type`.
`destination`	Specifies the destination queue to which messages consumed by this subscriber are propagated. The syntax and interpretation of this parameter depend on the value specified for `propagation_type`.
`rule`	Specifies an optional subscription rule used by the subscriber to dequeue messages from the source queue. This is `NULL` if no rule is needed. The syntax and interpretation of this parameter depend on the value specified for `propagation_type`.

Table 115-20 (Cont.) ADD_SUBSCRIBER Procedure Parameters

Parameter	Description
`transformation`	Specifies the transformation needed to convert between the Oracle Database Advanced Queuing payload and an ADT defined by Messaging Gateway. The type of transformation needed depends on the value specified for `propagation_type`. If `NULL`, then the Oracle Database Advanced Queuing payload type must be supported by Messaging Gateway.
`exception_queue`	Specifies a queue used for exception message logging purposes. This queue must be on the same messaging system as the propagation source. If `NULL`, then an exception queue is not used and propagation stops if a problem occurs. The syntax and interpretation of this parameter depend on the value specified for `propagation_type`. The source queue and exception queue cannot be the same queue.
`options`	Optional subscriber properties. `NULL` if there are none. Typically these are lesser used configuration properties supported by the messaging system.

Usage Notes

> **See Also:**
>
> "Handling Arbitrary Payload Types Using Message Transformations", in *Oracle Database Advanced Queuing User's Guide* for more information regarding message conversion and transformation

If the non-Oracle messaging link being accessed for the subscriber uses a JMS interface, then the Messaging Gateway agent will use the Oracle JMS interface to access the Oracle Database Advanced Queuing queues. Otherwise the native Oracle Database Advanced Queuing interface will be used. Parameters are interpreted differently when the Messaging Gateway agent uses Oracle JMS for JMS connections.

Transformations are not currently supported if the Oracle JMS interface is used for propagation. The transformation parameter must be `NULL`.

> **See Also:**
>
> For additional information regarding subscriber options
>
> - "WebSphere MQ System Properties" in *Oracle Database Advanced Queuing User's Guide*
> - "TIB/Rendezvous System Properties" in *Oracle Database Advanced Queuing User's Guide*

OUTBOUND_PROPAGATION Subscribers

The parameters for a subscriber used for outbound propagation are interpreted as follows:

- `queue_name` specifies the local Oracle Database Advanced Queuing queue that is the propagation source. This must have a syntax of `schema.queue`.
- `destination` specifies the foreign queue to which messages are propagated. This must have a syntax of `registered_queue@message_link`.
- `rule` specifies an optional Oracle Database Advanced Queuing subscriber rule if the native Oracle Database Advanced Queuing interface is used, or a JMS selector if the Oracle JMS interface is used. If `NULL`, then no rule or selector is used.
- `transformation` specifies the transformation used to convert the Oracle Database Advanced Queuing payload to an ADT defined by Messaging Gateway.

  Messaging Gateway propagation dequeues messages from the Oracle Database Advanced Queuing queue using the transformation to convert the Oracle Database Advanced Queuing payload to a known ADT defined by Messaging Gateway. The message is then enqueued in the foreign messaging system based on the Messaging Gateway ADT.
- `exception_queue` specifies the name of a local Oracle Database Advanced Queuing queue to which messages are moved if an exception occurs. This must have a syntax of `schema.queue`.

If the native Oracle Database Advanced Queuing interface is used, then a subscriber will be added to the Oracle Database Advanced Queuing queue when this procedure is called, whether or not Messaging Gateway is running. The local subscriber will be of the form `sys.aq$_agent('MGW_subscriber_id', NULL, NULL)`.

If the Oracle JMS interface is used, then the Messaging Gateway agent will create a JMS durable subscriber with the name of `MGW_subscriber_id`. If the agent is not running when this procedure is called, then the durable subscriber will be created the next time the agent starts.

The exception queue has the following caveats:

- The user is responsible for creating the Oracle Database Advanced Queuing queue to be used as the exception queue.
- The payload type of the source and exception queue must match.
- The exception queue must be created as a queue type of `DBMS_AQADM.NORMAL_QUEUE` rather than `DBMS_AQADM.EXCEPTION_QUEUE`. Enqueue restrictions prevent Messaging Gateway propagation from using an Oracle Database Advanced Queuing queue of type `EXCEPTION_QUEUE` as a Messaging Gateway exception queue.

INBOUND_PROPAGATION Subscribers

The parameters for a subscriber used for inbound propagation are interpreted as follows:

- `queue_name` specifies the foreign queue that is the propagation source. This must have a syntax of `registered_queue@message_link`.
- `destination` specifies the local Oracle Database Advanced Queuing queue to which messages are propagated. This must have a syntax of `schema.queue`.

- `rule` specifies an optional subscriber rule that is valid for the foreign messaging system. This is `NULL` if no rule is needed.
- `transformation` specifies the transformation used to convert an ADT defined by Messaging Gateway to the Oracle Database Advanced Queuing payload type.

  Messaging Gateway propagation dequeues messages from the foreign messaging system and converts the message body to a known ADT defined by Messaging Gateway. The transformation is used to convert the Messaging Gateway ADT to an Oracle Database Advanced Queuing payload type when the message is enqueued to the Oracle Database Advanced Queuing queue.
- `exception_queue` specifies the name of a foreign queue to which messages are moved if an exception occurs. This must have a syntax of `registered_queue@message_link`.

Whether or not a subscriber is needed depends on the requirements of the non-Oracle messaging system. If a durable subscriber is necessary, then it will be created by the Messaging Gateway agent. If the agent is not running at the time this procedure is called, then the creation of the subscriber on the non-Oracle messaging system will occur when the agent next starts.

The exception queue has the following caveats:

- The exception queue must be a registered non-Oracle queue.
- The source and exception queues must use the same messaging system link.

115.5.2 ALTER_AGENT Procedures

This procedure configures Messaging Gateway agent parameters.

Syntax

```
DBMS_MGWADM.ALTER_AGENT (
   max_memory       IN  BINARY_INTEGER DEFAULT NULL,
   max_threads      IN  BINARY_INTEGER DEFAULT NULL,
   service          IN  VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE );

DBMS_MGWADM.ALTER_AGENT (
   agent_name      IN   VARCHAR2,
   username        IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
   password        IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
   database        IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
   conntype        IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
   max_memory      IN   PLS_INTEGER DEFAULT NULL,
   max_threads     IN   PLS_INTEGER DEFAULT NULL,
   service         IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
   initfile        IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
   comment         IN   VARCHAR2  DEFAULT DBMS_MGWADM.NO_CHANGE );
```

Parameters

Table 115-21 ALTER_AGENT Procedure Parameters

Parameter	Description
`max_memory`	The maximum heap size, in MB, used by the Messaging Gateway agent. If it is `NULL`, then the current value is unchanged.

Table 115-21 (Cont.) ALTER_AGENT Procedure Parameters

Parameter	Description
max_threads	The number of messaging threads that the Messaging Gateway agent creates. If it is NULL, then the current value is unchanged. The maximum value of max_threads is limited to 128.
service	Specifies the database service that the Oracle Scheduler job class used by this agent will have affinity to. In an Oracle RAC environment, this means that the Messaging Gateway agent will run on only those database instances that are assigned to the service. If NULL, the job class used by this agent will be altered to belong to the default service which is mapped to every instance. If DBMS_MGWADM.NO_CHANGE, the current value is unchanged.
agent_name	Identifies the Messaging Gateway agent. DBMS_MGWADM.DEFAULT_AGENT specifies the default agent.
username	Specifies the username used for connections to the Oracle Database. NULL is not allowed. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged. If a username is specified then a password must also be specified.
password	Specifies the password used for connections to the Oracle Database. NULL is not allowed. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged. A password must be specified if a username is specified.
database	Specifies the database connect string used for connections to the Oracle Database. NULL indicates that a local connection should be used. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged.Oracle strongly recommends that a connect string, rather than NULL, be specified. Usually it will be a net service name from tnsnames.ora.
conntype	Specifies the type of connection to the Oracle Database, DBMS_MGWADM.JDBC_OCI or DBMS_MGWADM.JDBC_THIN. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged
initfile	Specifies a Messaging Gateway initialization file used by this agent. NULL indicates that the default initialization file is used. If a value is specified, it should be the full path name of the file. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged.
comment	Optional comments for this agent. NULL if a comment is not desired. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged.

Usage Notes

- Default values for these configuration parameters are set when the Messaging Gateway agent is installed.
- Changes to the max_memory and max_threads parameters take effect the next time the Messaging Gateway agent is active. If the Messaging Gateway agent is currently active, then it must be shut down and restarted for the changes to take effect.
- The service parameter is used to set an Oracle Scheduler job class attribute. The job class is used to create a Scheduler job that starts the Messaging Gateway agent. An Oracle administrator must create the database service. If the value is

NULL, the job class will belong to an internal service that is mapped to all instances.

- The `username`, `password`, and `database` parameters specify connection information used by the Messaging Gateway agent for connections to the Oracle Database. An Oracle administrator should create the user and grant it the role `MGW_AGENT_ROLE`.

115.5.3 ALTER_JOB Procedure

This procedure alters the properties of a propagation job.

Syntax

```
DBMS_MGWADM.ALTER_JOB (
   job_name          IN   VARCHAR2,
   rule              IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
   transformation    IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
   exception_queue   IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
   poll_interval     IN   PLS_INTEGER DEFAULT 0,
   options           IN   SYS.MGW_PROPERTIES DEFAULT NULL,
   comments          IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE );
```

Parameters

Table 115-22 ALTER_JOB Procedure Parameters

Parameter	Description
`job_name`	Identifies the propagation job
`rule`	Specifies an optional subscription rule used to dequeue messages from the propagation source. The syntax and interpretation of this parameter depend on the propagation type. A `NULL` value indicates that no subscription rule is needed. If `DBMS_MGWADM.NO_CHANGE`, then the current value is unchanged.
`transformation`	Specifies the transformation needed to convert between the Oracle Streams AQ payload and an ADT defined by Messaging Gateway. The type of transformation needed depends on the value specified for `propagation_type`. A `NULL` value indicates that no transformation is needed. If `DBMS_MGWADM.NO_CHANGE`, the current value is unchanged.
`exception_queue`	Specifies a queue used for exception message logging purposes. This queue must be on the same messaging system as the propagation source. In cases in which no exception queue is associated with the job, propagation stops if a problem occurs. The syntax and interpretation of this parameter depend on the propagation type. A `NULL` value indicates that no exception queue is used. If `DBMS_MGWADM.NO_CHANGE`, the current value is unchanged.

Table 115-22 (Cont.) ALTER_JOB Procedure Parameters

Parameter	Description
poll_interval	Specifies the polling interval, in seconds, used by the Messaging Gateway agent when checking for messages in the source queue. If no messages are available the agent will not poll again until the polling interval has passed. Once the agent detects a message it will continue propagating messages as long as any are available. Values: NULL, 0, or value > 0: • If zero (default), the current value will not be changed. • If NULL, the current value will be reset and the Messaging Gateway default polling interval will be used. The default polling interval is 5 seconds and can be overridden by the Messaging Gateway initialization file.
options	Optional job properties. If NULL, no options will be changed. If not NULL, then the properties specified in this list are combined with the current optional properties to form a new set of job options.
comments	An optional comment for this agent, or NULL if one is not desired. If DBMS_MGWADM.NO_CHANGE, the current value will not be changed.

Usage Notes

- If the non-Oracle messaging link being accessed for the propagation job uses a JMS interface, then the Messaging Gateway agent will use the Oracle JMS interface to access the Oracle Streams AQ queues. Otherwise the native Oracle Streams AQ interface will be used. Parameters are interpreted differently when the Messaging Gateway agent uses Oracle JMS for JMS connections.
- The subscriber rule cannot be altered when propagating from a JMS source. Instead, the propagation job must be dropped and re-created with the new rule. For JMS, changing the message selector on a durable subscription is equivalent to deleting and re-creating the subscription.
- Transformations are not currently supported if the Oracle JMS interface is used for propagation. The transformation parameter must be DBMS_MGWADM.NO_CHANGE (the default value).
- The options parameter specifies a set of properties used to alter the current optional properties. Each property affects the current property list in a particular manner; add a new property, replace an existing property, remove an existing property or remove all properties.

Note:

- SYS.MGW_PROPERTY Object Type for more information about the options parameter
- OUTBOUND_PROPAGATION Jobs for outbound propagation parameter interpretation
- INBOUND_PROPAGATION Jobs for inbound propagation parameter interpretation

115.5.4 ALTER_MSGSYSTEM_LINK Procedure for TIB/Rendezvous

This procedure alters the properties of a TIB/Rendezvous messaging system link.

Syntax

```
DBMS_MGWADM.ALTER_MSGSYSTEM_LINK (
   linkname      IN  VARCHAR2,
   properties    IN  SYS.MGW_TIBRV_PROPERTIES,
   options       IN  SYS.MGW_PROPERTIES DEFAULT NULL,
   comment       IN  VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE );
```

Parameters

Table 115-23 ALTER_MSGSYSTEM_LINK Procedure Parameters for TIB/Rendezvous

Parameters	Description
`linkname`	The messaging system link name
`properties`	Basic properties for a TIB/Rendezvous messaging system link. If `NULL`, then no link properties will be changed.
`options`	Optional link properties. If `NULL`, then no options will be changed. If not `NULL`, then the properties specified in this list are combined with the current options properties to form a new set of link options.
`comment`	A user-specified description, or `NULL` if one is not desired. If `DBMS_MGWADM.NO_CHANGE`, then the current value will not be changed.

Usage Notes

To retain an existing value for a messaging link property with a `VARCHAR2` datatype, specify `DBMS_MGWADM.NO_CHANGE` for that particular property. To preserve an existing value for a property of another datatype, specify `NULL` for that property.

The `options` parameter specifies a set of properties used to alter the current optional properties. Each property affects the current property list in a particular manner: add a new property, replace an existing property, remove an existing property, or remove all properties.

> **See Also:**
>
> SYS.MGW_PROPERTIES Object Type

Some properties cannot be modified, and this procedure will fail if an attempt is made to alter such a property. For properties and options that can be changed, a few are dynamic, and Messaging Gateway uses the new values immediately. Others require the Messaging Gateway agent to be shut down and restarted before they take effect.

> **See Also:**
>
> "TIB/Rendezvous System Properties" in *Oracle Database Advanced Queuing User's Guide* for more information about the messaging system properties and options

115.5.5 ALTER_MSGSYSTEM_LINK Procedure for WebSphere MQ

This procedure alters the properties of a WebSphere MQ messaging system link.

Syntax

```
DBMS_MGWADM.ALTER_MSGSYSTEM_LINK (
   linkname   IN  VARCHAR2,
   properties IN  SYS.MGW_MQSERIES_PROPERTIES,
   options    IN  SYS.MGW_PROPERTIES DEFAULT NULL,
   comment    IN  VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE);
```

Parameters

Table 115-24 ALTER_MSGSYSTEM_LINK Procedure Parameters for WebSphere MQ

Parameters	Description
`linkname`	The messaging system link name
`properties`	Basic properties for a WebSphere MQ messaging system link. If it is `NULL`, then no link properties are changed.
`options`	Optional link properties. `NULL` if no options are changed. If not `NULL`, then the properties specified in this list are combined with the current options properties to form a new set of link options.
`comment`	An optional description or `NULL` if not desired. If `DBMS_MGWADM.NO_CHANGE` is specified, then the current value is not changed.

Usage Notes

To retain an existing value for a messaging link property with a `VARCHAR2` datatype, specify `DBMS_MGWADM.NO_CHANGE` for that particular property. To preserve an existing value for a property of another datatype, specify `NULL` for that property.

The `options` parameter specifies a set of properties used to alter the current optional properties. Each property affects the current property list in a particular manner: add a new property, replace an existing property, remove an existing property, or remove all properties.

> **See Also:**
>
> SYS.MGW_PROPERTIES Object Type

Some properties cannot be modified, and this procedure will fail if an attempt is made to alter such a property. For properties and options that can be changed, a few are dynamic, and Messaging Gateway uses the new values immediately. Others require the Messaging Gateway agent to be shut down and restarted before they take effect.

> **See Also:**
>
> "WebSphere MQ System Properties" in *Oracle Database Advanced Queuing User's Guide* for more information about the messaging system properties and options

115.5.6 ALTER_PROPAGATION_SCHEDULE Procedure

This procedure alters a propagation schedule.

> **Note:**
>
> This subprogram has been deprecated as a result of improved technology (see ALTER_JOB Procedure), and is retained only for reasons of backward compatibility.

Syntax

```
DBMS_MGWADM.ALTER_PROPAGATION_SCHEDULE (
   schedule_id  IN VARCHAR2,
   duration     IN NUMBER DEFAULT NULL,
   next_time    IN VARCHAR2 DEFAULT NULL,
   latency      IN NUMBER DEFAULT NULL);
```

Parameters

Table 115-25 ALTER_PROPAGATION_SCHEDULE Procedure Parameters

Parameter	Description
`schedule_id`	Identifies the propagation schedule to be altered
`duration`	Reserved for future use
`next_time`	Reserved for future use
`latency`	Specifies the polling interval, in seconds, used by the Messaging Gateway agent when checking for messages in the source queue. If no messages are available in the source queue, then the agent will not poll again until the polling interval has passed. Once the agent detects a message it will continue propagating messages as long as any are available. Values: `NULL` or value > 0. If `latency` is `NULL`, then the Messaging Gateway agent default polling interval will be used. The default polling interval is 5 seconds, but it can be overridden by the Messaging Gateway initialization file.

Usage Notes

This procedure always overwrites the existing value for each parameter. If a given parameter is not specified, then the existing values are overwritten with the default value.

115.5.7 ALTER_SUBSCRIBER Procedure

This procedure alters the parameters of a subscriber used to consume messages from a source queue for propagation to a destination.

> **Note:**
>
> This subprogram has been deprecated as a result of improved technology (see ALTER_JOB Procedure), and is retained only for reasons of backward compatibility.

Syntax

```
DBMS_MGWADM.ALTER_SUBSCRIBER (
   subscriber_id    IN VARCHAR2,
   rule             IN VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
   transformation   IN VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
   exception_queue  IN VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
   options          IN SYS.MGW_PROPERTIES DEFAULT NULL );
```

Parameters

Table 115-26 ALTER_SUBSCRIBER Procedure Parameters

Parameter	Description
subscriber_id	Identifies the subscriber to be altered
rule	Specifies an optional subscription rule used by the subscriber to dequeue messages from the source queue. The syntax and interpretation of this parameter depend on the subscriber propagation type. A NULL value indicates that no subscription rule is needed. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged.
transformation	Specifies the transformation needed to convert between the Oracle Database Advanced Queuing payload and an ADT defined by Messaging Gateway. The type of transformation needed depends on the subscriber propagation type. A NULL value indicates that no transformation is needed. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged.
exception_queue	Specifies a queue used for exception message logging. This queue must be on the same messaging system as the propagation source. If no exception queue is associated with the subscriber, then propagation stops if a problem occurs. The syntax and interpretation of this parameter depend on the subscriber propagation type. A NULL value indicates that no exception queue is used. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged. The source queue and exception queue cannot be the same queue.

Table 115-26 (Cont.) ALTER_SUBSCRIBER Procedure Parameters

Parameter	Description
`options`	Optional subscriber properties. If `NULL`, then no options will be changed. If not `NULL`, then the properties specified in this list are combined with the current optional properties to form a new set of subscriber options.

Usage Notes

If the non-Oracle messaging link being accessed for the subscriber uses a JMS interface, then the Messaging Gateway agent will use the Oracle JMS interface to access the Oracle Database Advanced Queuing queues. Otherwise the native Oracle Database Advanced Queuing interface will be used. Parameters are interpreted differently when the Messaging Gateway agent uses Oracle JMS for JMS connections.

When propagating from a JMS source, the subscriber rule cannot be altered. Instead, the subscriber must be removed and added with the new rule. For JMS, changing the message selector on a durable subscription is equivalent to deleting and re-creating the subscription.

Transformations are not currently supported if the Oracle JMS interface is used for propagation. The transformation parameter must be `DBMS_MGWADM.NO_CHANGE` (the default value).

The `options` parameter specifies a set of properties used to alter the current optional properties. Each property affects the current property list in a particular manner: add a new property, replace an existing property, remove an existing property, or remove all properties.

- "INBOUND_PROPAGATION Subscribers for inbound propagation parameter interpretation

115.5.8 CLEANUP_GATEWAY Procedures

This procedure cleans up Messaging Gateway. The procedure performs cleanup or recovery actions that may be needed when Messaging Gateway is left in some abnormal or

unexpected condition. The MGW_GATEWAY view lists Messaging Gateway status and configuration information that pertains to the cleanup actions.

Syntax

```
DBMS_MGWADM.CLEANUP_GATEWAY(
   action       IN   BINARY_INTEGER,
   sarg         IN   VARCHAR2 DEFAULT NULL);

DBMS_MGWADM.CLEANUP_GATEWAY(
   agent_name   IN   VARCHAR2,   action       IN   BINARY_INTEGER,
sarg         IN   VARCHAR2 DEFAULT NULL );
```

Parameters

Table 115-27 CLEANUP_GATEWAY Procedure Parameters

Parameter	Description
action	The cleanup action to be performed. Values: • DBMS_MGWADM.CLEAN_STARTUP_STATE for Messaging Gateway start up state recovery • DBMS_MGWADM.CLEAN_LOG_QUEUES for log queue cleanup • DBMS_MGWADM.RESET_SUB_MISSING_LOG_REC for propagation job recovery due to missing log record • DBMS_MGWADM.RESET_SUB_MISSING_MESSAGE for propagation job recovery due to missing message
sarg	Optional argument whose meaning depends on the value specified for action. This should be NULL if it is not used for the specified action.
agent_name	Identifies the Messaging Gateway agent. DBMS_MGWADM.DEFAULT_AGENT specifies the default agent.

Usage Notes

CLEAN_STARTUP_STATE

sarg is not used and must be NULL.

The CLEAN_STARTUP_STATE action recovers Messaging Gateway to a known state when the Messaging Gateway agent has crashed or some other abnormal event occurs, and Messaging Gateway cannot be restarted. This should be done only when the Messaging Gateway agent has been started but appears to have crashed or has been nonresponsive for an extended period of time.

The CLEAN_STARTUP_STATE action may be needed when the MGW_GATEWAY view shows that the AGENT_STATUS value is something other than NOT_STARTED or START_SCHEDULED, and the AGENT_PING value is UNREACHABLE for an extended period of time.

If the AGENT_STATUS value is BROKEN, then the Messaging Gateway agent cannot be started until the problem has been resolved and the CLEAN_STARTUP_STATE action used to reset the agent status. A BROKEN status can indicate that the Messaging Gateway start job detected a Messaging Gateway agent already running. This condition that should never occur under normal use.

Cleanup tasks include:

- Removing the Scheduler job used to start the external Messaging Gateway agent process.
- Setting certain configuration information to a known state. For example, setting the agent status to `NOT_STARTED`.

Execution of this command fails if:

- The agent status is `NOT_STARTED` or `START_SCHEDULED`.
- No shutdown attempt has been made prior to calling this procedure, except if the agent status is `STARTING`.
- The Messaging Gateway agent is successfully contacted.

  The assumption is that the agent is active, and this procedure fails. If the agent does not respond after several attempts have been made, then the cleanup tasks are performed. This procedure takes at least several seconds and possibly up to one minute. This is expected behavior under conditions where this particular cleanup action is appropriate and necessary.

> **Note:**
>
> Terminate any Messaging Gateway agent process that may still be running after a `CLEAN_STARTUP_STATE` action has been successfully performed. This should be done before calling `DBMS_MGWADM.STARTUP` to start Messaging Gateway. The process is usually named `extprocmgwextproc`.

CLEAN_LOG_QUEUES

`sarg` is not used and must be `NULL`.

The Messaging Gateway agent will clean log queues for all configured messaging system links. The agent will temporarily stop all propagation activity and then remove all obsolete and bad log records from the log queues for all links. The procedure will fail if the Messaging Gateway agent is not running.

This cleanup action is automatically performed each time the Messaging Gateway agent is started.

> **Note:**
>
> The `CLEAN_LOG_QUEUES` action is performed only on agent startup. If this procedure is called when the agent is running, then the Messaging Gateway agent ignores it.

RESET_SUB_MISSING_LOG_REC

`sarg` specifies a Messaging Gateway job name (or subscriber ID) to be reset. It must not be `NULL`.

The Messaging Gateway agent recovers a Messaging Gateway propagation job that has failed due to a missing log record. The agent will reset the source and destination log records. The procedure will fail if the Messaging Gateway agent is not running.

> **Note:**
>
> If the messages in the source queue had already been propagated to the destination queue, then this action may result in duplicate messages.

RESET_SUB_MISSING_MESSAGE

`sarg` specifies a Messaging Gateway job name (or subscriber ID) to be reset. It must not be `NULL`.

The Messaging Gateway agent recovers a Messaging Gateway propagation job that has failed due to a missing persistent source message. The agent will treat the message as a non-persistent message and continue processing that propagation job. The procedure will fail if the Messaging Gateway agent is not running.

115.5.9 CREATE_AGENT Procedure

This procedure creates a Messaging Gateway agent that will be used to process propagation jobs.

Syntax

```
DBMS_MGWADM.CREATE_AGENT (
   agent_name     IN   VARCHAR2,
   username       IN   VARCHAR2 DEFAULT NULL,
   password       IN   VARCHAR2 DEFAULT NULL,
   database       IN   VARCHAR2 DEFAULT NULL,
   conntype       IN   VARCHAR2 DEFAULT DBMS_MGWADM.JDBC_OCI,
   max_memory     IN   PLS_INTEGER DEFAULT 64,
   max_threads    IN   PLS_INTEGER DEFAULT 1,
   service        IN   VARCHAR2 DEFAULT NULL,
   initfile       IN   VARCHAR2 DEFAULT NULL,
   comment        IN   VARCHAR2  DEFAULT NULL );
```

Parameters

Table 115-28 CREATE_AGENT Procedure Parameters

Parameter	Description
`agent_name`	A name used to identify the agent
`username`	Specifies the username used for connections to the Oracle Database
`password`	Specifies the password used for connections to the Oracle Database. A password must be specified if a username is specified.
`database`	Specifies the database connect string used for connections to the Oracle Database. `NULL` indicates that a local connection should be used. A value can be specified only if username is specified. Oracle strong recommends that a connect string, rather than `NULL` be specified. Usually it will be a net service name from `tnsnames.ora`.

Table 115-28 (Cont.) CREATE_AGENT Procedure Parameters

Parameter	Description
conntype	Specifies the type of connection to the Oracle Database.Values: DBMS_MGWADM.JDBC_OCI, DBMS_MGWADM.JDBC_THIN
max_memory	Specifies the maximum heap size, in MB, used by the Messaging Gateway agent
max_threads	Specifies the number of messaging threads that the Messaging Gateway agent creates. This determines the number of propagation jobs that the agent can concurrently process. The maximum value of max_threads is limited to 128.
service	Specifies the database service that the Oracle Scheduler job class used by this agent will have affinity to. In an Oracle RAC environment, this means that the Messaging Gateway agent will only run on those database instances that are assigned to the service. If NULL, then the job class will belong to the default service which is mapped to every instance.
initfile	Specifies a Messaging Gateway initialization file used by this agent. NULL indicates that the default initialization file is used. If a value is specified, it should be the full path name of the file.
comment	An optional comment for this agent. NULL if one is not desired.

Usage Notes

- The Messaging Gateway automatically configures a default agent when Messaging Gateway is installed. The name of the default agent is DEFAULT_AGENT. This procedure can be used to create additional agents.
- The username, password, and database parameters specify connection information used by the Messaging Gateway agent for connections to the Oracle Database. An Oracle administrator should create the database user and grant it the role MGW_AGENT_ROLE. It is not mandatory that the connection information be specified when this procedure is called but it must be set before the agent can be started.
- The service parameter is used to create an Oracle Scheduler job class. The job class is used to create a Scheduler job that starts the Messaging Gateway agent. An Oracle administrator must create the database service. If the value is NULL, the job class will belong to an internal service that is mapped to all instances.

115.5.10 CREATE_JOB Procedure

This procedure creates a job used to propagate message from a source to a destination.

Syntax

```
DBMS_MGWADM.CREATE_JOB (
   job_name           IN   VARCHAR2,
   propagation_type   IN   PLS_INTEGER,
   source             IN   VARCHAR2,
   destination        IN   VARCHAR2,
   rule               IN   VARCHAR2 DEFAULT NULL,
   transformation     IN   VARCHAR2 DEFAULT NULL,
   exception_queue    IN   VARCHAR2 DEFAULT NULL,
   poll_interval      IN   PLS_INTEGER DEFAULT NULL,
```

```
  options           IN   SYS.MGW_PROPERTIES DEFAULT NULL,
  enabled           IN   BOOLEAN DEFAULT TRUE,
  comments          IN   VARCHAR2 DEFAULT NULL);
```

Parameters

Table 115-29 CREATE_JOB Procedure Parameters

Parameter	Description
job_name	A user defined name to identify the propagation job
propagation_type	Specifies the type of message propagation. • DBMS_MGWADM.OUTBOUND_PROPAGATION for Oracle Streams AQ to non-Oracle propagation. • DBMS_MGWADM.INBOUND_PROPAGATION for non-Oracle to Oracle Streams AQ propagation.
source	Specifies the source queue whose messages are to be propagated. The syntax and interpretation of this parameter depend on the value specified for propagation_type.
destination	Specifies the destination queue to which messages are propagated. The syntax and interpretation of this parameter depend on the value specified for propagation_type.
rule	Specifies an optional subscription rule used to dequeue messages from the source queue. This should be NULL if no rule is needed. The syntax and interpretation of this parameter depend on the value specified for propagation_type.
transformation	Specifies the transformation needed to convert between the Oracle Streams AQ payload and an ADT defined by Messaging Gateway. The type of transformation needed depends on the value specified for propagation_type. If no transformation is specified the Oracle Streams AQ payload type must be supported by Messaging Gateway.
exception_queue	Specifies a queue used for exception message logging purposes. This queue must be on the same messaging system as the propagation source. If NULL, an exception queue will not be used and propagation will stop if a problem occurs. The syntax and interpretation of this parameter depend on the value specified for propagation_type. The source queue and exception queue cannot be the same queue.
poll_interval	Specifies the polling interval, in seconds, used by the Messaging Gateway agent when checking for messages in the source queue. If no messages are available the agent will not poll again until the polling interval has passed. Once the agent detects a message it will continue propagating messages as long as any are available. Values: NULL or value > 0. If NULL, then the Messaging Gateway default polling interval will be used. The default polling interval is 5 seconds and can be overridden by the Messaging Gateway initialization file.
options	Optional job properties, NULL if there are none. Typically these are lesser used configuration properties supported by the messaging system.

Table 115-29 (Cont.) CREATE_JOB Procedure Parameters

Parameter	Description
enabled	Specifies whether this propagation job is enabled after creation. Values: TRUE, FALSE. • If TRUE (default), the job will be enabled after it is created. • If FALSE, the job will be disabled after it is created. A propagation job must be enabled and the Messaging Gateway agent running before messages can be propagated.
comments	An optional comment for this job. NULL if one is not desired.

Usage Notes

- The job must be enabled and Messaging Gateway agent started in order for messages to be propagated.
- If the non-Oracle messaging link being accessed for the propagation job uses a JMS interface, then the Messaging Gateway agent will use the Oracle JMS interface to access the Oracle Streams AQ queues. Otherwise the native Oracle Streams AQ interface will be used. Parameters are interpreted differently when the Messaging Gateway agent uses Oracle JMS for JMS connections.
- Transformations are not currently supported if the Oracle JMS interface is used for propagation. The transformation parameter must be NULL.

OUTBOUND_PROPAGATION Jobs

The parameters for an outbound propagation job are interpreted as follows:

- source specifies the local Oracle Streams AQ queue that is the propagation source. This must have syntax of schema.queue. This can be either a multiple consumer queue or a single consumer queue.
- destination specifies the non-Oracle queue to which messages are propagated. This must have syntax of registered_queue@message_link.
- rule specifies an optional Oracle Streams AQ subscriber rule if the native Oracle Stream AQ interface is used, or a JMS selector if the Oracle JMS interface is used. If NULL, then no rule or selector is used. This parameter must be NULL if the native Oracle Stream AQ interface is used and the propagation source is a single consumer queue.
- transformation specifies the transformation used to convert the Oracle Streams AQ payload to an ADT defined by Messaging Gateway. The full transformation name (schema.name) should be used if one is specified.

  Messaging Gateway propagation dequeues messages from the Oracle Streams AQ queue using the transformation to convert the Oracle Streams AQ payload to a known ADT defined by Messaging Gateway. The message is then enqueued in the non-Oracle messaging system based on the Messaging Gateway ADT.
- exception_queue specifies the name of a local Oracle Streams AQ queue to which messages are moved if an exception occurs. The syntax must be schema.queue.

  If the native Oracle Streams AQ interface is used and the source is a multiple consumer queue, then a subscriber will be added to the Oracle Streams AQ queue when this procedure is called, whether or not the Messaging Gateway agent is running. The local subscriber will be of the form sys.aq$_agent('MGW_job_name', NULL, NULL).

If the Oracle JMS interface is used, then the Messaging Gateway agent will create a JMS durable subscriber with the name of `MGW_job_name`. If the agent is not running when this procedure is called, then the durable subscriber will be created the next time the agent starts.

The exception queue has the following conditions:

- The user is responsible for creating the Oracle Streams AQ queue to be used as the exception queue.
- The payload type of the source queue and exception queue must match.
- The exception queue must be created as a queue type of `DBMS_AQADM.NORMAL_QUEUE`. Enqueue restrictions prevent Messaging Gateway from using an Oracle Streams AQ queue of type `DBMS_AQADM.EXCEPTION_QUEUE` as a Messaging Gateway exception queue.

INBOUND_PROPAGATION Jobs

The parameters for an inbound propagation job are interpreted as follows:

- `source` specifies the non-Oracle queue that is the propagation source. The syntax must be `registered_queue@message_link`.
- `destination` specifies the local Oracle Streams AQ queue to which messages are propagated. The syntax must be `schema.queue`.
- `rule` specifies an optional subscriber rule that is valid for the non-Oracle messaging system. This should be `NULL` if no rule is needed.
- `transformation` specifies the transformation used to convert an ADT defined by Messaging Gateway to the Oracle Streams AQ payload type. The full transformation name (`schema.name`) should be used if one is specified

  Messaging Gateway propagation dequeues messages from the non-Oracle messaging system and converts the message body to a known ADT defined by Messaging Gateway. The transformation is used to convert the Messaging Gateway ADT to an Oracle Streams AQ payload type when the message is enqueued to the Oracle Streams AQ queue.
- `exception_queue` specifies the name of a registered non-Oracle queue to which messages are moved if an exception occurs. The syntax must be `registered_queue@message_link`.

  Whether or not a subscriber is needed for the source queue depends on the requirements of the non-Oracle messaging system. If a durable subscriber is necessary, then the Messaging Gateway agent will create it. If the agent is not running when this procedure is called, then the subscriber will be created on the non-Oracle messaging system the next time the agent starts.

  The exception queue has the following conditions:

  - The exception queue must be a registered non-Oracle queue.
  - The source queue and exception queue must use the same messaging system link.

115.5.11 CREATE_MSGSYSTEM_LINK Procedures for TIB/Rendezvous

This procedure creates a link to a TIB/Rendezvous messaging system.

Syntax

```
DBMS_MGWADM.CREATE_MSGSYSTEM_LINK (
   linkname     IN  VARCHAR2,
   properties   IN  SYS.MGW_TIBRV_PROPERTIES,
   options      IN  SYS.MGW_PROPERTIES DEFAULT NULL,
   comment      IN  VARCHAR2 DEFAULT NULL );

DBMS_MGWADM.CREATE_MSGSYSTEM_LINK (
   linkname     IN  VARCHAR2,
   agent_name   IN  VARCHAR2,
   properties   IN  SYS.MGW_TIBRV_PROPERTIES,
   options      IN  SYS.MGW_PROPERTIES DEFAULT NULL,
   comment      IN  VARCHAR2 DEFAULT NULL );
```

Parameters

Table 115-30 CREATE_MSGSYSTEM_LINK Procedure Parameters for TIB/Rendezvous

Parameter	Description
`linkname`	A user-defined name to identify this messaging system link
`properties`	Basic properties of a TIB/Rendezvous messaging system link.
`options`	Optional link properties. `NULL` if there are none. These are less frequently used configuration properties supported by the messaging system
`comment`	A user-specified description. `NULL` if one is not desired.
`agent_name`	Specifies the Messaging Gateway agent that will be used to process all propagation jobs associated with this link. `DBMS_MGWADM.DEFAULT_AGENT` specifies the default agent.

Usage Notes

The Messaging Gateway default agent will process the propagation jobs associated with this link if an agent name is not specified.

> **See Also:**
>
> "TIB/Rendezvous System Properties" in *Oracle Database Advanced Queuing User's Guide* for more information about the messaging system properties and options

115.5.12 CREATE_MSGSYSTEM_LINK Procedures for WebSphere MQ

This procedure creates a messaging system link to a WebSphere MQ messaging system.

Syntax

```
DBMS_MGWADM.CREATE_MSGSYSTEM_LINK(
   linkname    IN VARCHAR2,
   properties  IN SYS.MGW_MQSERIES_PROPERTIES,
   options     IN SYS.MGW_PROPERTIES DEFAULT NULL,
   comment     IN VARCHAR2 DEFAULT NULL);

DBMS_MGWADM.CREATE_MSGSYSTEM_LINK(
   linkname    IN VARCHAR2,
   agent_name  IN  VARCHAR2,
   properties  IN SYS.MGW_MQSERIES_PROPERTIES,
   options     IN SYS.MGW_PROPERTIES DEFAULT NULL,
   comment     IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 115-31 CREATE_MSGSYSTEM_LINK Procedure Parameters for WebSphere MQ

Parameter	Description
`linkname`	A user-defined name to identify the messaging system link
`properties`	Basic properties of a WebSphere MQ messaging system link
`options`	Optional link properties. `NULL` if there are none. These are less frequently used configuration properties supported by the messaging system.
`comment`	A user-specified description. `NULL` if one is not desired
`agent_name`	Specifies the Messaging Gateway agent that will be used to process all propagation jobs associated with this link. `DBMS_MGWADM.DEFAULT_AGENT` specifies the default agent.

Usage Notes

The Messaging Gateway default agent will process the propagation jobs associated with this link if an agent name is not specified.

> **See Also:**
>
> "WebSphere MQ System Properties" in *Oracle Database Advanced Queuing User's Guide* for more information about the messaging system properties and options

115.5.13 DB_CONNECT_INFO Procedure

This deprecated procedure configures connection information used by the Messaging Gateway default agent for connections to Oracle Database.

> **Note:**
>
> This subprogram has been deprecated as a result of improved technology (see ALTER_AGENT Procedures), and is retained only for reasons of backward compatibility.

Syntax

```
DBMS_MGWADM.DB_CONNECT_INFO (
   username      IN VARCHAR2,
   password      IN VARCHAR2,
   database      IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 115-32 DB_CONNECT_INFO Procedure Parameters

Parameter	Description
`username`	The username used for connections to Oracle Database. `NULL` is not allowed
`password`	The password used for connections to Oracle Database. `NULL` is not allowed
`database`	The database connect string used by the Messaging Gateway agent. `NULL` indicates that a local connection should be used. Oracle strongly recommends that a not `NULL` value be specified. Usually it will be a net service name from `tnsnames.ora`.

Usage Notes

The Messaging Gateway agent connects to Oracle Database as the user configured by this procedure. An Oracle administrator should create the user, grant it the role `MGW_AGENT_ROLE`, and then call this procedure to configure Messaging Gateway. Role `MGW_AGENT_ROLE` is used to grant this user special privileges needed to access Messaging Gateway configuration information stored in the database, enqueue or dequeue messages to and from Oracle Database Advanced Queuing queues, and perform certain Oracle Database Advanced Queuing administration tasks.

115.5.14 DISABLE_JOB Procedure

This procedure disables a propagation job.

Syntax

```
DBMS_MGWADM.DISABLE_JOB (
   job_name  IN VARCHAR2);
```

Parameters

Table 115-33 DISABLE_JOB Procedure Parameters

Parameter	Description
job_name	Identifies the propagation job

115.5.15 DISABLE_PROPAGATION_SCHEDULE Procedure

This **deprecated procedure** disables a propagation schedule.

> **Note:**
>
> This subprogram has been deprecated as a result of improved technology (see DISABLE_JOB Procedure), and is retained only for reasons of backward compatibility.

Syntax

```
DBMS_MGWADM.DISABLE_PROPAGATION_SCHEDULE (
   schedule_id  IN VARCHAR2);
```

Parameters

Table 115-34 DISABLE_PROPAGATION_SCHEDULE Procedure Parameters

Parameter	Description
schedule_id	Identifies the propagation schedule to be disabled

115.5.16 ENABLE_JOB Procedure

This procedure enables a propagation job.

Syntax

```
DBMS_MGWADM.ENABLE_JOB (
   job_name  IN VARCHAR2 );
```

Parameters

Table 115-35 ENABLE_JOB Procedure Parameters

Parameter	Description
job_name	Identifies the propagation job

115.5.17 ENABLE_PROPAGATION_SCHEDULE Procedure

This deprecated procedure enables a propagation schedule.

> **Note:**
>
> This subprogram has been deprecated as a result of improved technology (see ENABLE_JOB Procedure), and is retained only for reasons of backward compatibility.

Syntax

```
DBMS_MGWADM.ENABLE_PROPAGATION_SCHEDULE (
   schedule_id  IN VARCHAR2 );
```

Parameters

Table 115-36 ENABLE_PROPAGATION_SCHEDULE Procedure Parameters

Parameter	Description
schedule_id	Identifies the propagation schedule to be enabled

115.5.18 REGISTER_FOREIGN_QUEUE Procedure

This procedure registers a non-Oracle queue entity in Messaging Gateway.

Syntax

```
DBMS_MGWADM.REGISTER_FOREIGN_QUEUE(
   name            IN VARCHAR2,
   linkname        IN VARCHAR2,
   provider_queue  IN VARCHAR2 DEFAULT NULL,
   domain          IN INTEGER DEFAULT NULL,
   options         IN SYS.MGW_PROPERTIES DEFAULT NULL,
   comment         IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 115-37 REGISTER_FOREIGN_QUEUE Procedure Parameters

Parameters	Description
name	The registered queue name. This name identifies the foreign queue within Messaging Gateway and need not match the name of the queue in the foreign messaging system.
linkname	The link name for the messaging system on which this queue exists
provider_queue	The message provider (native) queue name. If NULL, then the value provided for the name parameter is used as the provider queue name.

Table 115-37 (Cont.) REGISTER_FOREIGN_QUEUE Procedure Parameters

Parameters	Description
`domain`	The domain type of the queue. `NULL` means the domain type is automatically determined based on the messaging system of the queue. `DBMS_MGWADM.DOMAIN_QUEUE` is for a queue (point-to-point model). `DBMS_MGWADM.DOMAIN_TOPIC` is for a topic (publish-subscribe model).
`options`	Optional queue properties
`comment`	A user-specified description. Can be `NULL`.

Usage Notes

This procedure does not create the physical queue in the non-Oracle messaging system. The non-Oracle queue must be created using the administration tools for that messaging system.

> **See Also:**
>
> For more information when registering queues for the WebSphere MQ messaging system or the TIB/Rendezvous messaging system, specifically "Optional Foreign Queue Configuration Properties" in *Oracle Database Advanced Queuing User's Guide*.

115.5.19 REMOVE_AGENT Procedure

This procedure removes a Messaging Gateway agent.

Syntax

```
DBMS_MGWADM.REMOVE_AGENT(
   agent_name   IN   VARCHAR2 );
```

Parameters

Table 115-38 REMOVE_AGENT Procedure Parameters

Parameters	Description
`agent_name`	Identifies the Messaging Gateway agent

Usage Notes

All messaging system links associated with this Messaging Gateway agent must be removed and the agent must be stopped before it can be removed. The Messaging Gateway default agent cannot be removed.

115.5.20 REMOVE_JOB Procedure

This procedure removes a propagation job.

Syntax

```
DBMS_MGWADM.REMOVE_JOB(
   job_name   IN   VARCHAR2,   force      IN   PLS_INTEGER DEFAULT
DBMS_MGWADM.NO_FORCE);
```

Parameters

Table 115-39 REMOVE_JOB Procedure Parameters

Parameters	Description
job_name	Identifies the propagation job
force	Specifies whether the procedure should succeed even if Messaging Gateway is not able to perform all cleanup actions pertaining to this propagation job. Values: DBMS_MGWADM.NO_FORCE, DBMS_MGWADM.FORCE • NO_FORCE (default) means the job is not removed if Messaging Gateway is unable to clean up successfully • FORCE means the job is removed even though all cleanup actions may not be done

Usage Notes

- The Messaging Gateway agent uses various resources of the Oracle Database and the non-Oracle messaging system for its propagation work. These resources need to be released when the job is removed. For example, Messaging Gateway may create a durable subscriber on the source queue that should be removed when the job is removed. Therefore, this procedure should normally be called when the Messaging Gateway agent is running and able to access the non-Oracle messaging system associated with this job.
- For outbound propagation, a local subscriber is removed from the Oracle Streams AQ queue when the propagation source is a multiple consumer queue.

115.5.21 REMOVE_MSGSYSTEM_LINK Procedure

This procedure removes a messaging system link for a non-Oracle messaging system.

Syntax

```
DBMS_MGWADM.REMOVE_MSGSYSTEM_LINK(
   linkname  IN VARCHAR2);
```

Parameters

Table 115-40 REMOVE_MSGSYSTEM_LINK Procedure Parameters

Parameters	Description
linkname	The messaging system link name

Usage Notes

All registered queues associated with this link must be removed before the messaging system link can be removed. This procedure fails if there is a registered foreign (non-Oracle) queue that references this link.

115.5.22 REMOVE_OPTION Procedure

This procedure removes a Messaging Gateway configuration option. It can be used to remove an agent option, a messaging link option, or a propagation job option.

Syntax

```
DBMS_MGWADM.REMOVE_OPTION (
   target_type   IN   PLS_INTEGER,
   target_name   IN   VARCHAR2,
   option_name   IN   VARCHAR2);
```

Parameters

Table 115-41 REMOVE_OPTION Procedure Parameters

Parameter	Description
target_type	Specifies the target type of the Messaging Gateway entity: • DBMS_MGWADM.AGENT_JAVA_PROP to remove a Java System property for a Messaging Gateway agent • DBMS_MGWADM.MSGLINK_OPTION to remove a messaging link option • DBMS_MGWADM.JOB_OPTION to remove a propagation job option
target_name	Name or identifier of the target. The value for this parameter depends on the value specified for target_type parameter. This must not be NULL.
option_name	Option name. This must not be NULL.

> **See Also:**
>
> Table 115-10 regarding options for the option_type parameter

Usage Notes

DBMS_MGWADM.AGENT_JAVA_PROP Target

The procedure removes an agent option used to set a Java System property when the Messaging Gateway agent is started. The agent must be restarted for the change to take effect.

The parameters are interpreted as follows:

- `target_name` specifies the name of the Messaging Gateway agent. `DBMS_MGWADM.DEFAULT_AGENT` can be used for the default agent.
- `option_name` specifies the Java System property
- `encrypted` can be either `TRUE` or `FALSE`

DBMS_MGWADM.MSGLINK_OPTION Target

The procedure removes a single option for a Messaging Gateway messaging system link. This is equivalent to calling `DBMS_MGWADM.ALTER_MSGSYSTEM_LINK` and using the options parameter to remove an option.

The parameters are interpreted as follows:

- `target_name` specifies the name of the message system link
- `option_name` specifies the option to set
- `encrypted` must be `FALSE`

DBMS_MGWADM.JOB_OPTION Target

The procedure removes a single option for a Messaging Gateway propagation job. This is equivalent to calling `DBMS_MGWADM.ALTER_JOB` and using the options parameter to remove an option.

The parameters are interpreted as follows:

- `target_name` specifies the name of the propagation job
- `option_name` specifies the option to set
- `encrypted` must be `FALSE`

115.5.23 REMOVE_SUBSCRIBER Procedure

This procedure removes a subscriber used to consume messages from a source queue for propagation to a destination.

> **Note:**
>
> This subprogram has been deprecated as a result of improved technology (see REMOVE_JOB Procedure), and is retained only for reasons of backward compatibility.

Syntax

```
DBMS_MGWADM.REMOVE_SUBSCRIBER (
   subscriber_id  IN VARCHAR2,
   force          IN BINARY_INTEGER DEFAULT DBMS_MGWADM.NO_FORCE );
```

Parameters

Table 115-42 REMOVE_SUBSCRIBER Procedure Parameters

Parameter	Description
subscriber_id	Identifies the subscriber to be removed
force	Specifies whether this procedure should succeed even if Messaging Gateway is not able to perform all cleanup actions pertaining to this subscriber. Values: DBMS_MGWADM.NO_FORCE, DBMS_MGWADM.FORCE • NO_FORCE means the subscriber is not removed if Messaging Gateway is unable to clean up successfully (default) • FORCE means the subscriber is removed even though all cleanup actions may not be done

Usage Notes

- The Messaging Gateway agent uses various resources of Oracle Database and the non-Oracle messaging system for its propagation work. These resources are typically associated with each subscriber and need to be released when the subscriber is no longer needed. Therefore, this procedure should only be called when the Messaging Gateway agent is running and able to access the non-Oracle messaging system associated with this subscriber.
- For outbound propagation, a local subscriber is removed from the Oracle Database Advanced Queuing queue.

115.5.24 RESET_JOB Procedure

This procedure resets the propagation error state for a propagation job.

Syntax

```
DBMS_MGWADM.RESET_JOB (
   job_name   IN   VARCHAR2);
```

Parameters

Table 115-43 RESET_JOB Procedure Parameters

Parameter	Description
job_name	Identifies the propagation job

Usage Notes

This procedure can be used to reset a propagation job that has been set to a failed state and propagation activities have been stopped. The administrator should correct the problem and then call this procedure to allow the agent to retry the propagation job. The STATUS field of the MGW_JOBS view indicates the job status.

115.5.25 RESET_SUBSCRIBER Procedure

This procedure resets the propagation error state for a subscriber.

> **Note:**
>
> This subprogram has been deprecated as a result of improved technology (see RESET_JOB Procedure), and is retained only for reasons of backward compatibility.

Syntax

```
DBMS_MGWADM.RESET_SUBSCRIBER (
   subscriber_id  IN VARCHAR2 );
```

Parameters

Table 115-44 RESET_SUBSCRIBER Procedure Parameters

Parameter	Description
subscriber_id	Identifies the subscriber

115.5.26 SCHEDULE_PROPAGATION Procedure

This procedure schedules message propagation from a source to a destination.

The schedule must be enabled and Messaging Gateway started in order for messages to be propagated.

> **Note:**
>
> This subprogram has been deprecated as a result of improved technology (see CREATE_JOB Procedure), and is retained only for reasons of backward compatibility.

Syntax

```
DBMS_MGWADM.SCHEDULE_PROPAGATION (
   schedule_id       IN VARCHAR2,
   propagation_type  IN BINARY_INTEGER,
   source            IN VARCHAR2,
   destination       IN VARCHAR2,
   start_time        IN DATE DEFAULT SYSDATE,
   duration          IN NUMBER DEFAULT NULL,
   next_time         IN VARCHAR2 DEFAULT NULL,
   latency           IN NUMBER DEFAULT NULL);
```

Parameters

Table 115-45 SCHEDULE_PROPAGATION Procedure Parameters

Parameter	Description
schedule_id	Specifies a user-defined name that identifies the schedule
propagation_type	Specifies the type of message propagation. DBMS_MGWADM.OUTBOUND_PROPAGATION is for Oracle Database Advanced Queuing to non-Oracle propagation. DBMS_MGWADM.INBOUND_PROPAGATION is for non-Oracle to Oracle Database Advanced Queuing propagation.
source	Specifies the source queue whose messages are to be propagated. The syntax and interpretation of this parameter depend on the value specified for propagation_type.
destination	Specifies the destination queue to which messages are propagated. The syntax and interpretation of this parameter depend on the value specified for propagation_type.
start_time	Reserved for future use
duration	Reserved for future use
next_time	Reserved for future use
latency	Specifies the polling interval, in seconds, used by the Messaging Gateway agent when checking for messages in the source queue. If no messages are available in the source queue, then the agent will not poll again until the polling interval has passed. Once the agent detects a message it will continue propagating messages as long as any are available. Values: NULL or value > 0. If latency is NULL, then the Messaging Gateway agent default polling interval will be used. The default polling interval is 5 seconds but it can be overridden by the Messaging Gateway initialization file.

Usage Notes

For outbound propagation, parameters are interpreted as follows:

- source specifies the local Oracle Database Advanced Queuing queue from which messages are propagated. This must have a syntax of schema.queue.
- destination specifies the foreign queue to which messages are propagated. This must have a syntax of registered_queue@message_link.

For inbound propagation, parameters are interpreted as follows:

- source specifies the foreign queue from which messages are propagated. This must have a syntax of registered_queue@message_link.
- destination specifies the local Oracle Database Advanced Queuing queue to which messages are propagated. This must have a syntax of schema.queue.

The schedule is set to an enabled state when it is created.

115.5.27 SET_LOG_LEVEL Procedures

This procedure dynamically alters the Messaging Gateway agent logging level. The Messaging Gateway agent must be running.

Syntax

```
DBMS_MGWADM.SET_LOG_LEVEL (
   log_level    IN   BINARY_INTEGER);

DBMS_MGWADM.SET_LOG_LEVEL (
   agent_name   IN   VARCHAR2,
   log_level    IN   BINARY_INTEGER);
```

Parameters

Table 115-46 SET_LOG_LEVEL Procedure Parameters

Parameter	Description
log_level	Level at which the Messaging Gateway agent logs information. DBMS_MGWADM.BASIC_LOGGING generates the least information while DBMS_MGWADM.TRACE_DEBUG_LOGGING generates the most information.
agent_name	Identifies the Messaging Gateway agent. DBMS_MGWADM.DEFAULT_AGENT specifies the default agent.

> **See Also:**
>
> Table 115-3 for details on the log_level parameter

115.5.28 SET_OPTION Procedure

This procedure sets a Messaging Gateway configuration option. It can be used to set an agent option, a messaging link option, or a propagation job option.

Syntax

```
DBMS_MGWADM.SET_OPTION (
   target_type   IN   PLS_INTEGER,
   target_name   IN   VARCHAR2,
   option_name   IN   VARCHAR2,
   option_value  IN   VARCHAR2,
   encrypted     IN   BOOLEAN DEFAULT FALSE );
```

Parameters

Table 115-47 SET_OPTION Procedure Parameters

Parameter	Description
target_type	Specifies the target type of the Messaging Gateway entity: • DBMS_MGWADM.AGENT_JAVA_PROP to set a Java System property for a Messaging Gateway agent • DBMS_MGWADM.MSGLINK_OPTION to set a messaging link option • DBMS_MGWADM.JOB_OPTION to set a propagation job option
target_name	Name or identifier of the target. The value for this parameter depends on the value specified for target_type parameter. This must not be NULL.
option_name	Option name. This must not be NULL.
option_value	Option value
encrypted	Indicates whether the value should be stored as encrypted: • TRUE if the value should be stored in an encrypted form • FALSE if the value should be stored in a cleartext form

> **See Also:**
>
> Table 115-10 regarding options for the option_type parameter

Usage Notes

DBMS_MGWADM.AGENT_JAVA_PROP Target

The procedure will store an agent option used to set a Java System property when the Messaging Gateway agent is started. The agent must be restarted for the change to take effect.

The parameters are interpreted as follows:

- target_name specifies the name of the Messaging Gateway agent. DBMS_MGWADM.DEFAULT_AGENT can be used for the default agent.
- option_name specifies the Java System property
- encrypted can be either TRUE or FALSE

DBMS_MGWADM.MSGLINK_OPTION Target

The procedure will set or alter a single option for a Messaging Gateway messaging system link. This is equivalent to calling DBMS_MGWADM.ALTER_MSGSYSTEM_LINK and using the options parameter to set an option.

The parameters are interpreted as follows:

- target_name specifies the name of the message system link
- option_name specifies the option to set

- encrypted must be FALSE

DBMS_MGWADM.JOB_OPTION Target

The procedure will set or alter a single option for a Messaging Gateway propagation job. This is equivalent to calling DBMS_MGWADM.ALTER_JOB and using the options parameter to set an option.

The parameters are interpreted as follows:

- target_name specifies the name of the propagation job
- option_name specifies the option to set
- encrypted must be FALSE

115.5.29 SHUTDOWN Procedures

This procedure shuts down the Messaging Gateway agent. No propagation activity occurs until Messaging Gateway is restarted.

Syntax

```
DBMS_MGWADM.SHUTDOWN (
   sdmode      IN BINARY_INTEGER DEFAULT DBMS_MGWADM.SHUTDOWN_NORMAL);

DBMS_MGWADM.SHUTDOWN (
   agent_name  IN VARCHAR2);
```

Parameters

Table 115-48 SHUTDOWN Procedure Parameters

Parameter	Description
sdmode	The shutdown mode. The only value currently supported is DBMS_MGWADM.SHUTDOWN_NORMAL for normal shutdown. The Messaging Gateway agent may attempt to complete any propagation work currently in progress.
agent_name	Identifies the Messaging Gateway agent. DBMS_MGWADM.DEFAULT_AGENT specifies the default agent.

Usage Notes

The Messaging Gateway default agent is shut down if no agent name is specified.

115.5.30 STARTUP Procedures

This procedure starts the Messaging Gateway agent. It must be called before any propagation activity can take place.

Syntax

```
DBMS_MGWADM.STARTUP(
   instance       IN  BINARY_INTEGER DEFAULT 0,
   force          IN  BINARY_INTEGER DEFAULT DBMS_MGWADM.NO_FORCE);
```

```
DBMS_MGWADM.STARTUP(
   agent_name     IN  VARCHAR2);
```

Parameters

Table 115-49 STARTUP Procedure Parameters

Parameter	Description
instance	Specifies which instance can run the job queue job used to start the Messaging Gateway agent. If this is zero, then the job can be run by any instance. **Caution: This parameter has been deprecated**.
force	If this is DBMS_MGWADM.FORCE, then any positive integer is acceptable as the job instance. If this is DBMS_MGWADM.NO_FORCE (the default), then the specified instance must be running; otherwise the routine raises an exception. **Caution: This parameter has been deprecated**.
agent_name	Identifies the Messaging Gateway agent. DBMS_MGWADM.DEFAULT_AGENT specifies the default agent.

Usage Notes

- The Messaging Gateway default agent will be started if an agent name is not specified.
- The force and instance parameters are no longer used and will be ignored. If the instance affinity parameters were being used to start the default agent on a specific instance, the administrator will need to create a database service and then assign that service to the default agent using the DBMS_MGWADM.ALTER_AGENT procedure.
- The Messaging Gateway agent cannot be started until an agent user has been configured by the DBMS_MGWADM.CREATE_AGENT or DBMS_MGWADM.ALTER_AGENT subprograms.

115.5.31 UNREGISTER_FOREIGN_QUEUE Procedure

This procedure removes a non-Oracle queue entity in Messaging Gateway.

Syntax

```
DBMS_MGWADM.UNREGISTER_FOREIGN_QUEUE(
   name         IN VARCHAR2,
   linkname     IN VARCHAR2);
```

Parameters

Table 115-50 UNREGISTER_FOREIGN_QUEUE Procedure Parameters

Parameter	Description
name	The queue name

Table 115-50 (Cont.) UNREGISTER_FOREIGN_QUEUE Procedure Parameters

Parameter	Description
linkname	The link name for the messaging system on which the queue exists

Usage Notes

- This procedure does not remove the physical queue in the non-Oracle messaging system.
- All propagation jobs, subscribers and schedules referencing this queue must be removed before it can be unregistered. This procedure fails if a propagation job, subscriber, or propagation schedule references the non-Oracle queue.

115.5.32 UNSCHEDULE_PROPAGATION Procedure

This deprecated procedure removes a propagation schedule.

> **Note:**
>
> This subprogram has been deprecated as a result of improved technology (see REMOVE_JOB Procedure), and is retained only for reasons of backward compatibility.

Syntax

```
DBMS_MGWADM.UNSCHEDULE_PROPAGATION (
   schedule_id   IN VARCHAR2 );
```

Parameters

Table 115-51 UNSCHEDULE_PROPAGATION Procedure Parameters

Parameter	Description
schedule_id	Identifies the propagation schedule to be removed

116
DBMS_MGWMSG

DBMS_MGWMSG provides object types used by the canonical message types to convert message bodies, and methods, constants, and subprograms for working with Messaging Gateway message types.

This chapter contains the following topics:

- Security Model
- Constants
- Types
- Summary of DBMS_MGWMSG Subprograms

> **See Also:**
>
> DBMS_MGWADM which describes the Messaging Gateway administrative interface, DBMS_MGWADM

116.1 DBMS_MGWMSG Security Model

The EXECUTE privilege is granted to PUBLIC on all types defined in the DBMS_MGWMSG package as well as the canonical types. The DBMS_MGWMSG packages and object types are owned by SYS.

> **Note:**
>
> You must run the catmgw.sql script to load the Messaging Gateway packages and object types into the database. Refer to the *Oracle Database Advanced Queuing User's Guide* for information on loading database objects and using DBMS_MGWMSG.

116.2 DBMS_MGWMSG Constants

The DBMS_MGWMSG package defines constants for specifying various parameter values.

Table 116-1 DBMS_MGWMSG Constants: Value Types and Constants Representing the Type of Value for a SYS.MGW_NAME_VALUE_T Object

Value	Constant
TEXT_VALUE	CONSTANT BINARY_INTEGER := 1
RAW_VALUE	CONSTANT BINARY_INTEGER := 2

Table 116-1 (Cont.) DBMS_MGWMSG Constants: Value Types and Constants Representing the Type of Value for a SYS.MGW_NAME_VALUE_T Object

Value	Constant
BOOLEAN_VALUE	CONSTANT BINARY_INTEGER := 3
BYTE_VALUE	CONSTANT BINARY_INTEGER := 4
SHORT_VALUE	CONSTANT BINARY_INTEGER := 5
INTEGER_VALUE	CONSTANT BINARY_INTEGER := 6
LONG_VALUE	CONSTANT BINARY_INTEGER := 7
FLOAT_VALUE	CONSTANT BINARY_INTEGER := 8
DOUBLE_VALUE	CONSTANT BINARY_INTEGER := 9
DATE_VALUE	CONSTANT BINARY_INTEGER := 10

Table 116-2 DBMS_MGWMSG Constants: Boolean Values—Constants Representing a Boolean as a Numeric Value

Value	Constant
BOOLEAN_FALSE	CONSTANT BINARY_INTEGER := 0
BOOLEAN_TRUE	CONSTANT BINARY_INTEGER := 1

Table 116-3 DBMS_MGWMSG Constants: Case Comparisons

Value	Constant
CASE_SENSITIVE	CONSTANT BINARY_INTEGER := 0
CASE_INSENSITIVE	CONSTANT BINARY_INTEGER := 1

Table 116-4 Constants for the TIB/Rendezvous field type

Value	Constant
TIBRVMSG_BOOL	CONSTANT INTEGER := 1
TIBRVMSG_F32	CONSTANT INTEGER := 2
TIBRVMSG_F64	CONSTANT INTEGER := 3
TIBRVMSG_I8	CONSTANT INTEGER := 4
TIBRVMSG_I16	CONSTANT INTEGER := 5
TIBRVMSG_I32	CONSTANT INTEGER := 6
TIBRVMSG_I64	CONSTANT INTEGER := 7
TIBRVMSG_IPADDR32	CONSTANT INTEGER := 8
TIBRVMSG_IPPORT16	CONSTANT INTEGER := 9
TIBRVMSG_DATETIME	CONSTANT INTEGER := 10
TIBRVMSG_F32ARRAY	CONSTANT INTEGER := 11
TIBRVMSG_F64ARRAY	CONSTANT INTEGER := 12

Table 116-4 (Cont.) Constants for the TIB/Rendezvous field type

Value	Constant
TIBRVMSG_I8ARRAY	CONSTANT INTEGER := 13
TIBRVMSG_I16ARRAY	CONSTANT INTEGER := 14
TIBRVMSG_I32ARRAY	CONSTANT INTEGER := 15
TIBRVMSG_I64ARRAY	CONSTANT INTEGER := 16
TIBRVMSG_OPAQUE	CONSTANT INTEGER := 17
TIBRVMSG_STRING	CONSTANT INTEGER := 18
TIBRVMSG_XML	CONSTANT INTEGER := 19

116.3 DBMS_MGWMSG Types

DBMS_MGWMSG uses types to specify certain information.

- SYS.MGW_NAME_VALUE_T Type
- SYS.MGW_NAME_VALUE_T Type-Attribute Mapping
- SYS.MGW_NAME_TYPE_ARRAY_T Type
- SYS.MGW_TEXT_VALUE_T Type
- SYS.MGW_RAW_VALUE_T Type
- SYS.MGW_BASIC_MSG_T Type
- SYS.MGW_NUMBER_ARRAY_T Type
- SYS.MGW_TIBRV_FIELD_T Type
- SYS.MGW_TIBRV_MSG_T Type

116.3.1 DBMS_MGWMSG SYS.MGW_NAME_VALUE_T Type

This type specifies a named value.

The name attribute, type attribute, and one of the <>_value attributes are typically not NULL.

Syntax

```
TYPE SYS.MGW_NAME_VALUE_T IS OBJECT(
   name               VARCHAR2(250),
   type               INTEGER,
   integer_value      INTEGER,
   number_value       NUMBER,
   text_value         VARCHAR2(4000),
   raw_value          RAW(2000),
   date_value         DATE,

-- Methods
STATIC FUNCTION CONSTRUCT
RETURN SYS.MGW_NAME_VALUE_T,

STATIC FUNCTION CONSTRUCT_BOOLEAN (
   name   IN VARCHAR2,
```

```
   value  IN INTEGER )
RETURN SYS.MGW_NAME_VALUE_T,

STATIC FUNCTION CONSTRUCT_BYTE (
   name   IN VARCHAR2,
   value  IN INTEGER )
RETURN SYS.MGW_NAME_VALUE_T,

STATIC FUNCTION CONSTRUCT_SHORT (
   name   IN VARCHAR2,
   value  IN INTEGER )
RETURN SYS.MGW_NAME_VALUE_T,

STATIC FUNCTION CONSTRUCT_INTEGER (
   name   IN VARCHAR2,
   value  IN INTEGER )
RETURN SYS.MGW_NAME_VALUE_T,

STATIC FUNCTION CONSTRUCT_LONG (
   name   IN VARCHAR2,
   value  IN NUMBER )
RETURN SYS.MGW_NAME_VALUE_T,

STATIC FUNCTION CONSTRUCT_FLOAT (
   name   IN VARCHAR2,
   value  IN NUMBER )
RETURN SYS.MGW_NAME_VALUE_T,

STATIC FUNCTION CONSTRUCT_DOUBLE (
   name   IN VARCHAR2,
   value  IN NUMBER )
RETURN SYS.MGW_NAME_VALUE_T,

STATIC FUNCTION CONSTRUCT_TEXT (
   name   IN VARCHAR2,
   value  IN VARCHAR2 )
RETURN SYS.MGW_NAME_VALUE_T,

STATIC FUNCTION CONSTRUCT_RAW (
   name   IN VARCHAR2,
   value  IN RAW )
RETURN SYS.MGW_NAME_VALUE_T,

STATIC FUNCTION CONSTRUCT_DATE (
   name   IN VARCHAR2,
   value  IN DATE )
RETURN SYS.MGW_NAME_VALUE_T );
```

Attributes

Table 116-5 SYS.MGW_NAME_VALUE_T Attributes

Attribute	Description
name	Name associated with the value
type	Value type. Refer to the DBMS_MGWMSG.<>_VALUE constants in Table 116-1. This indicates which Java datatype and class are associated with the value. It also indicates which attribute stores the value.

Table 116-5 (Cont.) SYS.MGW_NAME_VALUE_T Attributes

Attribute	Description
integer_value	Stores a numeric integer value
number_value	Stores a numeric float or large integer value
text_value	Stores a text value
raw_value	Stores a RAW (bytes) value
date_value	Stores a date value

SYS.MGW_NAME_VALUE_T Type-Attribute Mapping

Table 116-6 shows the mapping between the value type and the attribute used to store the value.

Table 116-6 SYS.MGW_NAME_VALUE_T Type Attribute Mapping

Type	Value Stored in Attribute
DBMS_MGWMSG.TEXT_VALUE	text_value
DBMS_MGWMSG.RAW_VALUE	raw_value
DBMS_MGWMSG.BOOLEAN_VALUE	integer_value
DBMS_MGWMSG.BYTE_VALUE	integer_value
DBMS_MGWMSG.SHORT_VALUE	integer_value
DBMS_MGWMSG.INTEGER_VALUE	integer_value
DBMS_MGWMSG.LONG_VALUE	number_value
DBMS_MGWMSG.FLOAT_VALUE	number_value
DBMS_MGWMSG.DOUBLE_VALUE	number_value
DBMS_MGWMSG.DATE_VALUE	date_value

CONSTRUCT Method

This method constructs a new SYS.MGW_NAME_VALUE_T instance. All attributes are assigned a value of NULL.

Syntax

```
STATIC FUNCTION CONSTRUCT
RETURN SYS.MGW_NAME_VALUE_T;
```

CONSTRUCT_*TYPE* Methods

These methods construct a new SYS.MGW_NAME_VALUE_T instance initialized with the value of a specific type. Each method sets the name and type attributes and one of the <>_value attributes, as shown in the mappings in Table 116-6.

Syntax

```
STATIC FUNCTION CONSTRUCT_<> (
   name   IN VARCHAR2,
```

```
   value  IN datatype )
RETURN SYS.MGW_NAME_VALUE_T;
```

Usage Notes

The `construct_boolean` method sets the value to either `DBMS_MGWMSG.BOOLEAN_TRUE` or `DBMS_MGWMSG.BOOLEAN_FALSE`.

116.3.2 DBMS_MGWMSG SYS.MGW_NAME_TYPE_ARRAY_T Type

This type specifies an array of name-value pairs. An object of `SYS.MGW_NAME_VALUE_ARRAY_T` type can have up to 1024 elements.

Syntax

```
TYPE SYS.MGW_NAME_VALUE_ARRAY_T
  AS VARRAY (1024) OF SYS.MGW_NAME_VALUE_T;
```

116.3.3 DBMS_MGWMSG SYS.MGW_TEXT_VALUE_T Type

This type specifies a `TEXT` value. It can store a large value as a `CLOB` or a smaller value (size <= 4000) as `VARCHAR2`. Only one of the `< >_ value` attributes should be set.

Syntax

```
TYPE SYS.MGW_TEXT_VALUE_T IS OBJECT(
   small_value VARCHAR2(4000),
   large_value CLOB,

-- Methods
STATIC FUNCTION CONSTRUCT
RETURN SYS.MGW_TEXT_VALUE_T);
```

Attributes

Table 116-7 SYS.MGW_TEXT_VALUE_T Attributes

Attribute	Description
`small_value`	Small TEXT value. Used for values <= 4000.
`large_value`	Large TEXT value. Used when the value is too large for the `small_value` attribute.

CONSTRUCT Method

This method constructs a new `SYS.MGW_TEXT_VALUE_T` instance. All attributes are assigned a value of `NULL`.

Syntax

```
STATIC FUNCTION CONSTRUCT
RETURN SYS.MGW_TEXT_VALUE_T;
```

116.3.4 DBMS_MGWMSG SYS.MGW_RAW_VALUE_T Type

This type specifies a RAW value. This type can store a large value as a BLOB or a smaller value (size <= 2000) as RAW. You must set no more than one of the < >_value attributes.

Syntax

```
TYPE SYS.MGW_RAW_VALUE_T IS OBJECT(
   small_value RAW(2000),
   large_value BLOB,

--Methods
STATIC FUNCTION CONSTRUCT
RETURN SYS.MGW_RAW_VALUE_T);
```

Attributes

Table 116-8 SYS.MGW_RAW_VALUE_T Attributes

Attribute	Description
small_value	Small RAW (bytes) value <= 2000
large_value	Large RAW value. Used when the value is too large for the small_value attribute.

CONSTRUCT Method

This method constructs a new SYS.MGW_RAW_VALUE_T instance. All attributes are assigned a value of NULL.

Syntax

```
STATIC FUNCTION CONSTRUCT
RETURN SYS.MGW_RAW_VALUE_T;
```

116.3.5 DBMS_MGWMSG SYS.MGW_BASIC_MSG_T Type

This is a canonical type for a basic TEXT or RAW message. Only a single TEXT or RAW value is typically set. An object of this type must not have both TEXT and RAW set to a not NULL value at the same time.

Syntax

```
TYPE SYS.MGW_BASIC_MSG_T IS OBJECT(
   header     SYS.MGW_NAME_VALUE_ARRAY_T,
   text_body  SYS.MGW_TEXT_VALUE_T,
   raw_body   SYS.MGW_RAW_VALUE_T,

--Methods
STATIC FUNCTION CONSTRUCT
RETURN SYS.MGW_BASIC_MSG_T);
```

Attributes

Table 116-9 SYS.MGW_BASIC_MSG_T Attributes

Attribute	Description
header	Message header information as an array of name-value pairs
text_body	Message body for a TEXT message
raw_body	Message body for a RAW (bytes) message

CONSTRUCT Method

This method constructs a new SYS.MGW_BASIC_MSG_T instance. All attributes are assigned a value of NULL.

Syntax

```
STATIC FUNCTION CONSTRUCT
RETURN SYS.MGW_BASIC_MSG_T;
```

116.3.6 DBMS_MGWMSG SYS.MGW_NUMBER_ARRAY_T Type

A type that specifies an array of numbers.

Syntax

```
TYPE SYS.MGW_NUMBER_ARRAY_T AS VARRAY(1024) OF NUMBER;
```

116.3.7 DBMS_MGWMSG SYS.MGW_TIBRV_FIELD_T Type

This type represents a TIB/Rendezvous message field, typically used in a read-only fashion to retrieve field information from a SYS.MGW_TIBRV_MSG_T instance.

Syntax

```
TYPE SYS.MGW_TIBRV_FIELD_T IS OBJECT(
   field_name       VARCHAR2(256),
   field_id         INTEGER,
   field_type       INTEGER,
   number_value     NUMBER,
   number_array_value  SYS.MGW_NUMBER_ARRAY_T,
   text_value       VARCHAR2(4000),
   raw_value        RAW(2000),
   date_value       DATE,
   clob_value       CLOB,
   blob_value       BLOB);
```

Attributes

Table 116-10 SYS.MGW_TIBRV_FIELD_T Attributes

Attribute	Description
field_name	Field name. This will be NULL if the field has no name.

Table 116-10 (Cont.) SYS.MGW_TIBRV_FIELD_T Attributes

Attribute	Description
field_id	Field identifier. If the field identifier is zero (0), then that field is considered not to have a field identifier. Otherwise the field identifier is a nonzero value that is unique for all fields of that message.
field_type	Field wire format datatype. The DBMS_MGWMSG.TIBRVMSG_<> constants represent valid values for this attribute. The value of this field discriminates which value attribute is used to store the field data.
number_value	Used to store a numeric value
number_array_value	Used to store a numeric array value
text_value	Used to store a small text value
raw_value	Used to store a small raw value
date_value	Used to store a date value
clob_value	Used to store a large text value. This is used when the text data will not fit in text_value, that is, when size is larger than 4000.
blob_value	Used to store a large raw value. This is used when the raw data will not fit in raw_value; that is, when size is larger than 2000.

SYS.MGW_TIBRV_FIELD_T Type and Attribute Mapping

Table 116-11 describes the mapping in type SYS.MGW_TIBRV_FIELD_T between the field type and attribute used to store the value.

Table 116-11 SYS.MGW_TIBRV_FIELD_T Type and Attribute Mapping

Field Type (DBMS_MGWMSG constant)	Value Stored in Attribute
TIBRVMSG_BOOL	number_value
TIBRVMSG_F32	number_value
TIBRVMSG_F64	number_value
TIBRVMSG_I8	number_value
TIBRVMSG_I16	number_value
TIBRVMSG_I32	number_value
TIBRVMSG_I64	number_value
TIBRVMSG_IPADDR32	text_value
TIBRVMSG_IPPORT16	number_value
TIBRVMSG_DATETIME	date_value
TIBRVMSG_F32ARRAY	number_array_value
TIBRVMSG_F64ARRAY	number_array_value
TIBRVMSG_I8ARRAY	number_array_value
TIBRVMSG_I16ARRAY	number_array_value
TIBRVMSG_I32ARRAY	number_array_value

Table 116-11 (Cont.) SYS.MGW_TIBRV_FIELD_T Type and Attribute Mapping

Field Type (DBMS_MGWMSG constant)	Value Stored in Attribute
TIBRVMSG_I64ARRAY	number_array_value
TIBRVMSG_OPAQUE	raw_value or blob_value
TIBRVMSG_STRING	text_value or clob_value
TIBRVMSG_XML	raw_value or blob_value

116.3.8 DBMS_MGWMSG SYS.MGW_TIBRV_MSG_T Type

This type represents a TIB/Rendezvous message. You must never directly reference the attributes of this type. Instead use the type methods.

Syntax

```
TYPE SYS.MGW_TIBRV_MSG_T IS OBJECT(
   send_subject    VARCHAR2(256),
   reply_subject   VARCHAR2(256),
   cm_time_limit   NUMBER,
   cm_sender_name  VARCHAR2(256),
   cm_sequence_num NUMBER,
   fields          SYS.MGW_TIBRV_IFIELDS_T,
   clob_data1      CLOB,
   clob_data2      CLOB,
   clob_data3      CLOB,
   blob_data1      BLOB,
   blob_data2      BLOB,
   blob_data3      BLOB,

STATIC FUNCTION construct

RETURN INTEGER
);
```

Attributes

Table 116-12 SYS.MGW_TIBRV_MSG_T Type Attributes

Attribute	Description
send_subject	Send subject name
reply_subject	Reply subject name
cm_time_limit	Time limit for a certified message
cm_sender_name	Sender name of a certified message
cm_sequence_num	Sequence number of a certified message
fields	Collection of message fields
clob_data1	Used to store a large text value
clob_data2	Used to store a large text value
clob_data3	Used to store a large text value
blob_data1	Used to store a large raw value
blob_data2	Used to store a large raw value
blob_data3	Used to store a large raw value

Construct Method

Constructs a new `SYS.MGW_TIBRV_MSG_T` instance. All attributes are set to `NULL`.

Syntax

```
STATIC FUNCTION construct
RETURN SYS.MGW_TIBRV_MSG_T;
```

ADD_<> Methods

Adds a new field to the message.

Syntax

```
MEMBER PROCEDURE ADD_<> (
   name  IN  VARCHAR2,
   id    IN  INTEGER,
   value IN  datatype );
```

Parameters

Table 116-13 SYS.MGW_TIBRV_MSG_T ADD_<> Method Parameters

Parameter	Description
name	Field name
id	Field identifier
value	Field data

Table 116-14 shows, for each add method, the field type that will be assigned and valid values for the field data.

Table 116-14 MGW_TIBRV_MSG_T Add Method Field Types

Method Name	Field Type Assigned	Comment
add_bool	TIBRVMSG_BOOL	Valid values: 0 (false), 1 (true)
add_f32	TIBRVMSG_F32	n/a
add_f64	TIBRVMSG_F64	n/a
add_i8	TIBRVMSG_I8	Valid range: -128...127
add_i16	TIBRVMSG_I16	Valid range: -32768...32767
add_i32	TIBRVMSG_I32	Valid range: -2147483648... 2147483647
add_i64	TIBRVMSG_I64	n/a
add_ipaddr32	TIBRVMSG_IPADDR32	n/a
add_ipport16	TIBRVMSG_IPPORT16	n/a
add_datetime	TIBRVMSG_DATETIME	n/a
add_f32array	TIBRVMSG_F32ARRAY	n/a
add_f64array	TIBRVMSG_F64ARRAY	n/a
add_i8array	TIBRVMSG_I8ARRAY	Valid range: -128...127
add_i16array	TIBRVMSG_I16ARRAY	Valid range: -32768...32767
add_i32array	TIBRVMSG_I32ARRAY	Valid range: -2147483648... 2147483647
add_i64array	TIBRVMSG_I64ARRAY	n/a
add_opaque	TIBRVMSG_OPAQUE	Value stored as RAW if size < 2000; otherwise value stored in BLOB
add_string	TIBRVMSG_STRING	Value stored as VARCHAR2 if size < 4000; otherwise value stored in CLOB
add_xml	TIBRVMSG_XML	Value stored as RAW if size < 2000; otherwise value stored in BLOB

SET_<> Methods

Accessor methods to set an instance attribute to a specific value.

Syntax

```
MEMBER PROCEDURE SET_<> (
  value IN datatype );
```

Parameters

Table 116-15 SYS.MGW_TIBRV_MSG_T SET_<> Method Parameters

Parameter	Description
value	Value to be assigned

GET_<> Methods

Accessor methods to retrieve the value for an instance attribute.

Syntax

```
MEMBER PROCEDURE GET_<>
RETURN datatype;
```

Parameters

None

Return Values

Returns the attribute value.

GET_FIELD_COUNT Function

Gets the number of message fields.

Syntax

```
MEMBER PROCEDURE get_field_count
RETURN INTEGER;
```

Parameters

None

Return Values

Returns the number of fields, or zero (0) if there are none.

GET_FIELD Function

Retrieves field information for the field having a given field collection index. This method should only be called if the `GET_FIELD_COUNT Function` returns a nonzero value and `idx` must specify a valid collection index; that is, `1<=idx<=get_field_count()`.

Syntax

```
MEMBER PROCEDURE get_field (
    idx    IN    INTEGER )
RETURN SYS.MGW_TIBRV_FIELD_T;
```

Parameters

Table 116-16 SYS.MGW_TIBRV_MSG_T GET_FIELD Function Parameters

Parameter	Description
idx	Specifies the 1-based field collection index of the field to retrieve

> **Note:**
>
> A 1-based index begins at one (1) instead of zero (0).

Return Values

Returns the field information.

GET_FIELD_BY_NAME Function

Retrieves field information for the first field that has a given field name. The name comparison is case-sensitive.

Syntax

```
MEMBER PROCEDURE get_field_by_name (
   name  IN   VARCHAR2 )
RETURN SYS.MGW_TIBRV_FIELD_T;
```

Parameters

Table 116-17 SYS.MGW_TIBRV_MSG_T GET_FIELD_BY_NAME Function Parameters

Parameter	Description
name	Specifies the field name to search for. This can be NULL to find the first field that does not have a field name.

Return Values

Returns the field information, or NULL if no match was found.

GET_FIELD_BY_ID Function

Retrieves field information for the first field that has a given field identifier.

A field can have either a unique identifier or no identifier. If the field identifier value is zero (0) or NULL, then the field is considered to have no identifier. Otherwise, the identifier is a nonzero value that is unique for all the fields of this message.

Syntax

```
MEMBER PROCEDURE get_field_by_id (
   id   IN  INTEGER )
RETURN SYS.MGW_TIBRV_FIELD_T;
```

Parameters

Table 116-18 SYS.MGW_TIBRV_MSG_T GET_FIELD_BY_ID Function Parameters

Parameter	Description
`id`	Specifies the field identifier to search for. This can be zero (0) or `NULL` to find the first field that does not have an identifier.

Return Values

Returns the field information, or `NULL` if no match was found.

FIND_FIELD_NAME Function

Searches for a field with a given field name, starting from a given index of the field collection. It returns the index of that field. The name comparison is case-sensitive. This function is useful for finding all the fields that have the same name.

Syntax

```
MEMBER PROCEDURE find_field_name (
   name      IN  VARCHAR2,
   start_idx IN  INTEGER )
RETURN INTEGER;
```

Parameters

Table 116-19 SYS.MGW_TIBRV_MSG_T FIND_FIELD_NAME Function Parameters

Parameter	Description
`name`	Specifies the field name to search for. This can be `NULL` to search for a field that does not have a field name.
`start_idx`	Specifies the 1-based field collection index from which the search should start.

Return Values

Returns the field index (> 0) if a match was found, or zero (0) if no match was found.

FIND_FIELD_ID Function

Searches for a field with a given field identifier, starting from a given index of the field collection. It returns the index of that field.

Syntax

```
MEMBER PROCEDURE find_field_id (
     id        IN  INTEGER,
     start_idx IN INTEGER )
RETURN    INTEGER;
```

Parameters

Table 116-20 SYS.MGW_TIBRV_MSG_T FIND_FIELD_ID Function Parameters

Parameter	Description
`id`	Specifies the field identifier to search for. This can be zero (0) or `NULL` to find a field that does not have an identifier.
`start_idx`	Specifies the 1-based field collection index from which the search should start.

Return Values

Returns the field index (> 0) if a match was found, or zero (0) if no match was found.

116.4 Summary of DBMS_MGWMSG Subprograms

This table lists the `DDBMS_MGWMSG` subprograms and briefly describes them.

Table 116-21 DBMS_MGWMSG Package Subprograms

Subprogram	Description
LCR_TO_XML Function	Converts a SYS.ANYDATA object encapsulating a row LCR (`LCR$_ROW_RECORD`) or a DDL LCR (`LCR$_DDL_RECORD`) to a `SYS.XMLTYPE` object
NVARRAY_ADD Procedure	Appends a name-value element to the end of a name-value array
NVARRAY_FIND_NAME Function	Searches a name-value array for the element with the name you specify in `p_name`
NVARRAY_FIND_NAME_TYPE Function	Searches a name-value array for an element with the name and value type you specify
NVARRAY_GET Function	Gets the name-value element of the name you specify in `p_name` from a name-value array
NVARRAY_GET_BOOLEAN Function	Gets the value of the name-value array element that you specify in `p_name` and with the `BOOLEAN_VALUE` value type
NVARRAY_GET_BYTE Function	Gets the value of the name-value array element that you specify in `p_name` and with the `BYTE_VALUE` value type
NVARRAY_GET_DATE Function	Gets the value of the name-value array element that you specify in `p_name` and with the `DATE_VALUE` value type
NVARRAY_GET_DOUBLE Function	Gets the value of the name-value array element that you specify in `p_name` and with the `DOUBLE_VALUE` value type
NVARRAY_GET_FLOAT Function	Gets the value of the name-value array element that you specify in `p_name` and with the `FLOAT_VALUE` value type
NVARRAY_GET_INTEGER Function	Gets the value of the name-value array element that you specify in `p_name` and with the `INTEGER_VALUE` value type
NVARRAY_GET_LONG Function	Gets the value of the name-value array element that you specify in `p_name` and with the `LONG_VALUE` value type
NVARRAY_GET_RAW Function	Gets the value of the name-value array element that you specify in `p_name` and with the `RAW_VALUE` value type
NVARRAY_GET_SHORT Function	Gets the value of the name-value array element that you specify in `p_name` and with the `SHORT_VALUE` value type

Table 116-21 (Cont.) DBMS_MGWMSG Package Subprograms

Subprogram	Description
NVARRAY_GET_TEXT Function	Gets the value of the name-value array element that you specify in p_name and with the TEXT_VALUE value type
XML_TO_LCR Function	Converts a SYS.XMLTYPE object to a SYS.ANYDATA object encapsulating a row LCR (LCR$_ROW_RECORD) or a DDL LCR (LCR$_DDL_RECORD)

116.4.1 LCR_TO_XML Function

This function converts a SYS.ANYDATA object encapsulating a row LCR (Logical Change Record, in this case a LCR$_ROW_RECORD) or a DDL LCR (LCR$_DDL_RECORD) to a SYS.XMLTYPE object.

> **See Also:**
>
> XML_TO_LCR Function

Syntax

```
DBMS_MGWMSG.LCR_TO_XML (
   p_anydata IN SYS.ANYDATA )
 RETURN SYS.XMLTYPE;
```

Parameters

Table 116-22 LCR_TO_XML Function Parameters

Parameter	Description
p_anydata	An ANYDATA object to be converted

Return Values

Returns a SYS.XMLTYPE object.

Usage Notes

An exception is raised if the encapsulated type p_anydata is not an LCR.

116.4.2 NVARRAY_ADD Procedure

This procedure appends a name-value element to the end of a name-value array.

Syntax

```
DBMS_MGWMSG.NVARRAY_ADD (
   p_array  IN OUT SYS.MGW_NAME_VALUE_ARRAY_T,
   p_value  IN     SYS.MGW_NAME_VALUE_T );
```

Parameters

Table 116-23 NVARRAY_ADD Procedure Parameters

Parameter	Description
p_array	On input, the name-value array instance to modify. If NULL, then a new array is created. On output, the modified name-value array instance.
p_value	The value to add. If NULL, then p_array is not changed.

116.4.3 NVARRAY_FIND_NAME Function

This function searches a name-value array for the element with the name you specify in p_name.

Syntax

```
DBMS_MGWMSG.NVARRAY_FIND_NAME (
   p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,
   p_name     IN VARCHAR2,
   p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )
RETURN BINARY_INTEGER;
```

Parameters

Table 116-24 NVARRAY_FIND_NAME Function Parameters

Parameters	Description
p_array	The name-value array to search
p_name	The name to find
p_compare	Name comparison method. Values are CASE_SENSITIVE and CASE_INSENSITIVE.

Return Values

Returns a positive integer that is the array index of the matching element or zero (0) if the specified name is not found.

116.4.4 NVARRAY_FIND_NAME_TYPE Function

This function searches a name-value array for an element with the name and value type you specify.

Syntax

```
DBMS_MGWMSG.NVARRAY_FIND_NAME_TYPE (
   p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,
   p_name     IN VARCHAR2,
   p_type     IN BINARY_INTEGER
   p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )
RETURN BINARY_INTEGER;
```

Parameters

Table 116-25 NVARRAY_FIND_NAME_TYPE Function Parameters

Parameter	Description
p_array	The name-value array to search
p_name	The name to find
p_type	The value type. Refer to the value type constants in Table 116-1 .
p_compare	Name comparison method. Values are CASE_SENSITIVE and CASE_INSENSITIVE.

Return Values

Returns a positive integer that is the array index of the matching element, zero (0) if the specified name is not found, or negative one (-1) if the specified name is found but a type mismatch exists.

116.4.5 NVARRAY_GET Function

This function gets the name-value element of the name you specify in p_name from a name-value array.

Syntax

```
DBMS_MGWMSG.NVARRAY_GET (
   p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,
   p_name     IN VARCHAR2,
   p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )
RETURN SYS.MGW_NAME_VALUE_T;
```

Parameters

Table 116-26 NVARRAY_GET Function Parameters

Parameter	Description
p_array	The name-value array
p_name	The value name
p_compare	Name comparison method. Values are CASE_SENSITIVE and CASE_INSENSITIVE.

Return Values

Returns the matching element, or NULL if the specified name is not found.

116.4.6 NVARRAY_GET_BOOLEAN Function

This function gets the value of the name-value array element that you specify in `p_name` and with the `BOOLEAN_VALUE` value type.

Syntax

```
DBMS_MGWMSG.NVARRAY_GET_BOOLEAN (
   p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,
   p_name     IN VARCHAR2,
   p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )
RETURN INTEGER;
```

Parameters

Table 116-27 NVARRAY_GET_BOOLEAN Function Parameters

Parameter	Description
`p_array`	The name-value array
`p_name`	The value name
`p_compare`	Name comparison method. Values are `CASE_SENSITIVE` and `CASE_INSENSITIVE`.

Return Values

Returns the value, or `NULL` if either the specified name is not found or a type mismatch exists.

116.4.7 NVARRAY_GET_BYTE Function

This function gets the value of the name-value array element that you specify in `p_name` and with the `BYTE_VALUE` value type.

Syntax

```
DBMS_MGWMSG.NVARRAY_GET_BYTE (
   p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,
   p_name     IN VARCHAR2,
   p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )
RETURN INTEGER;
```

Parameters

Table 116-28 NVARRAY_GET_BYTE Function Parameters

Parameter	Description
`p_array`	The name-value array
`p_name`	The value name
`p_compare`	Name comparison method. Values are `CASE_SENSITIVE` and `CASE_INSENSITIVE`.

Return Values

Returns the value, or NULL if either the specified name is not found or a type mismatch exists.

116.4.8 NVARRAY_GET_DATE Function

This function gets the value of the name-value array element that you specify in p_name and with the DATE_VALUE value type.

Syntax

```
DBMS_MGWMSG.NVARRAY_GET_DATE (
   p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,
   p_name     IN VARCHAR2,
   p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )
RETURN DATE;
```

Parameters

Table 116-29 NVARRAY_GET_DATE Function Parameters

Parameters	Description
p_array	The name-value array
p_name	The value name
p_compare	Name comparison method. Values are CASE_SENSITIVE and CASE_INSENSITIVE.

Return Values

Returns the value, or NULL if either the specified name is not found or a type mismatch exists.

116.4.9 NVARRAY_GET_DOUBLE Function

This function gets the value of the name-value array element that you specify in p_name and with the DOUBLE_VALUE value type.

Syntax

```
DBMS_MGWMSG.NVARRAY_GET_DOUBLE (
   p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,
   p_name     IN VARCHAR2,
   p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )
RETURN NUMBER;
```

Parameters

Table 116-30 NVARRAY_GET_DOUBLE Function Parameters

Parameter	Description
p_array	The name-value array
p_name	The value name

Table 116-30 (Cont.) NVARRAY_GET_DOUBLE Function Parameters

Parameter	Description
p_compare	Name comparison method. Values are CASE_SENSITIVE and CASE_INSENSITIVE.

Return Values

Returns the value, or NULL if either the specified name is not found or a type mismatch exists.

116.4.10 NVARRAY_GET_FLOAT Function

This function gets the value of the name-value array element that you specify in p_name and with the FLOAT_VALUE value type.

Syntax

```
DBMS_MGWMSG.NVARRAY_GET_FLOAT (
   p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,
   p_name     IN VARCHAR2,
   p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )
RETURN NUMBER;
```

Parameters

Table 116-31 NVARRAY_GET_FLOAT Function Parameters

Parameter	Description
p_array	The name-value array
p_name	The value name
p_compare	Name comparison method. Values are CASE_SENSITIVE and CASE_INSENSITIVE.

Return Values

Returns the value, or NULL if either the specified name is not found or a type mismatch exists.

116.4.11 NVARRAY_GET_INTEGER Function

This function gets the value of the name-value array element that you specify in p_name and with the INTEGER_VALUE value type.

Syntax

```
DBMS_MGWMSG.NVARRAY_GET_INTEGER (
   p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,
   p_name     IN VARCHAR2,
   p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )
RETURN INTEGER;
```

Parameters

Table 116-32 NVARRAY_GET_INTEGER Function Parameters

Parameter	Description
p_array	The name-value array
p_name	The value name
p_compare	Name comparison method. Values are CASE_SENSITIVE and CASE_INSENSITIVE.

Return Values

Returns the value, or NULL if either the specified name is not found or a type mismatch exists.

116.4.12 NVARRAY_GET_LONG Function

This function gets the value of the name-value array element that you specify in p_name and with the LONG_VALUE value type.

Syntax

```
DBMS_MGWMSG.NVARRAY_GET_LONG (
   p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,
   p_name     IN VARCHAR2,
   p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )
RETURN NUMBER;
```

Parameters

Table 116-33 NVARRAY_GET_LONG Function Parameters

Parameter	Description
p_array	The name-value array
p_name	The value name
p_compare	Name comparison method. Values are CASE_SENSITIVE and CASE_INSENSITIVE.

Return Values

Returns the value, or NULL if either the specified name is not found or a type mismatch exists.

116.4.13 NVARRAY_GET_RAW Function

This function gets the value of the name-value array element that you specify in p_name and with the RAW_VALUE value type.

Syntax

```
DBMS_MGWMSG.NVARRAY_GET_RAW (
   p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,
   p_name     IN VARCHAR2,
```

```
   p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )
RETURN RAW;
```

Parameters

Table 116-34 NVARRAY_GET_RAW Function Parameters

Parameter	Description
p_array	The name-value array
p_name	The value name
p_compare	Name comparison method. Values are CASE_SENSITIVE and CASE_INSENSITIVE.

Return Values

Returns the value, or NULL if either the specified name is not found or a type mismatch exists.

116.4.14 NVARRAY_GET_SHORT Function

This function gets the value of the name-value array element that you specify in p_name and with the SHORT_VALUE value type.

Syntax

```
DBMS_MGWMSG.NVARRAY_GET_SHORT (
   p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,
   p_name     IN VARCHAR2,
   p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )
RETURN INTEGER;
```

Parameters

Table 116-35 NVARRAY_GET_SHORT Function Parameters

Parameter	Description
p_array	The name-value array
p_name	The value name
p_compare	Name comparison method. Values are CASE_SENSITIVE and CASE_INSENSITIVE.

Return Values

Returns the value, or NULL if either the specified name is not found or a type mismatch exists.

116.4.15 NVARRAY_GET_TEXT Function

This function gets the value of the name-value array element that you specify in `p_name` and with the `TEXT_VALUE` value type.

Syntax

```
DBMS_MGWMSG.NVARRAY_GET_TEXT (
   p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,
   p_name     IN VARCHAR2,
   p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )
RETURN VARCHAR2;
```

Parameters

Table 116-36 NVARRAY_GET_TEXT Function Parameters

Parameter	Description
`p_array`	The name-value array
`p_name`	The value name
`p_compare`	Name comparison method. Values are `CASE_SENSITIVE` and `CASE_INSENSITIVE`.

Return Values

Returns the value, or `NULL` if either the specified name is not found or a type mismatch exists.

116.4.16 XML_TO_LCR Function

This function converts a `SYS.XMLTYPE` object to a `SYS.ANYDATA` object encapsulating a row LCR (`LCR$_ROW_RECORD`) or a DDL LCR (`LCR$_DDL_RECORD`).

> **See Also:**
>
> LCR_TO_XML Function

Syntax

```
DBMS_MGWMSG.XML_TO_LCR (
   p_xmldata IN SYS.XMLTYPE )
 RETURN SYS.ANYDATA;
```

Parameters

Table 116-37 XML_TO_LCR Function Parameters

Parameter	Description
`p_xmldata`	An XMLTYPE object representing an LCR

Return Values

Returns a `SYS.ANYDATA` object.

Usage Notes

An exception is raised if `p_xmldata` cannot be converted to an LCR.

117
DBMS_MLE

The DBMS_MLE package allows users to execute JavaScript code inside the Oracle Database and exchange data seamlessly between PL/SQL and JavaScript. The JavaScript code itself can execute PL/SQL and SQL through built-in JavaScript modules. JavaScript data types are automatically mapped to Oracle Database data types and vice versa.

With the DBMS_MLE package, developers can write their data processing logic in JavaScript.

This chapter contains the following topics:

- DBMS_MLE Overview
- DBMS_MLE Security Model
- Summary of DBMS_MLE Subprograms

117.1 DBMS_MLE Overview

Runtime state for MLE execution is encapsulated in execution contexts that users can explicitly create and destroy. Users can also export values from PL/SQL to MLE, and import values from MLE back into PL/SQL.

The following example captures the typical workflow for MLE execution:

```
set serveroutput on;
declare
  ctx dbms_mle.context_handle_t;
  source clob;
  greeting varchar2(100);
begin
  ctx := dbms_mle.create_context(); -- Create execution context for MLE execution
  dbms_mle.export_to_mle(ctx, 'person', 'World'); -- Export value from PL/SQL
  source := q'~
    var bindings = require("mle-js-bindings");
    var person = bindings.importValue("person"); // Import value previously exported
from PL/SQL
    var greeting = "Hello, " + person + "!";
    bindings.exportValue("greeting", greeting); // Export value to PL/SQL
  ~';
  dbms_mle.eval(ctx, 'JAVASCRIPT', source); -- Evaluate the source code snippet in the
execution context
  dbms_mle.import_from_mle(ctx, 'greeting', greeting); -- Import value previously
exported from MLE
  dbms_output.put_line('Greetings from MLE: ' || greeting);
  dbms_mle.drop_context(ctx); -- Drop the execution context once no longer required
end;
/
```

Executing the above code block produces the following output:

```
Greetings from MLE: Hello, World!
```

117.2 DBMS_MLE Security Model

Access to MLE features is protected by database privileges. The user must have the `EXECUTE DYNAMIC MLE` privilege while calling any of its functions and procedures that pertain to MLE execution. In addition to this, the user must also have the `EXECUTE` privilege on an MLE language (for example, `EXECUTE ON JAVASCRIPT`) to execute code in that language. An `ORA-01031` error is raised if the user calling any of the `DBMS_MLE` subprograms does not have the appropriate privileges. See the summary of `DBMS_MLE` subprograms for the privileges required to call each `DBMS_MLE` subprogram.

117.3 Summary of DBMS_MLE Subprograms

This table lists the `DBMS_MLE` subprograms and briefly describes them.

Table 117-1 DBMS_MLE Package Subprograms

Subprogram	Description
CREATE_CONTEXT Function	Creates an MLE context for executing snippets in any MLE language.
DISABLE_CTX_STDERR Procedure	This procedure disables stderr stream of the specified MLE context, so that future writes to stderr are discarded.
DISABLE_CTX_STDOUT Procedure	This procedure disables stdout stream of the specified MLE context, so that future writes to `stdout` are discarded.
DISABLE_STDERR Procedure	This procedure disables the stderr stream of all MLE contexts, so that future writes to `stderr` are discarded.
DISABLE_STDOUT Procedure	This procedure disables the stdout stream of all MLE contexts, so that future writes to stdout are discarded.
DROP_CONTEXT Procedure	This procedure is used to drop an MLE context that was previously created using the `CREATE_CONTEXT` procedure. After the context is dropped, the context handle is no longer valid and cannot be used anymore.
EVAL Procedure	This procedure executes the given MLE language code within the context identified by the context handle.
EXPORT_TO_MLE Procedure	This procedure allows you to assign the given value, with appropriate conversion, to the named property in the MLE context. The property is created if it is not already present.
GET_AVAILABLE_LANGUAGES Function	This function returns the set of available MLE languages.
GET_CTX_ERROR_STACK Function	This function retrieves the MLE language stack trace for the most recent application error in the given execution context.
IMPORT_FROM_MLE Procedure	This procedure retrieves the value of the named property from the MLE context and converts it to the requested PL/SQL type.
SET_CTX_STDERR Procedure	This procedure redirects the stderr stream of the MLE context to the given `CLOB`.
SET_CTX_STDERR_TO_DBMS_OUTPUT Procedure	This procedure redirects the stderr stream of the MLE context to `DBMS_OUTPUT`.
SET_CTX_STDOUT Procedure	This procedure redirects the stdout stream of the MLE context to the given `CLOB`.
SET_CTX_STDOUT_TO_DBMS_OUTPUT Procedure	This procedure redirects the stdout stream of the MLE context to `DBMS_OUTPUT`.

Table 117-1 (Cont.) DBMS_MLE Package Subprograms

Subprogram	Description
SET_STDERR Procedure	This procedure redirects the stderr stream of all MLE contexts to the given CLOB.
SET_STDERR_TO_DBMS_OUTPUT Procedure	This procedure redirects the stderr stream of all MLE contexts to DBMS_OUTPUT.
SET_STDOUT Procedure	This procedure redirects the stdout stream of all MLE contexts to the given CLOB.
SET_STDOUT_TO_DBMS_OUTPUT Procedure	This procedure redirects the stdout stream of all MLE contexts to DBMS_OUTPUT.

117.3.1 CREATE_CONTEXT Function

Creates an MLE context for executing snippets in any MLE language. You need the EXECUTE DYNAMIC MLE privilege to execute this function.

Syntax

```
DBMS_MLE.CREATE_CONTEXT
 RETURN CONTEXT_HANDLE_T;
```

Return Values

This function returns a handle that uniquely identifies a context within a session for use in subsequent operations, such as EXPORT_TO_MLE and EVAL.

Usage Notes

A context has a lifetime limited to the session in which it was created. When a client session is terminated, all its contexts are dropped. All MLE contexts created in a session are also dropped when the session state is reset, for example, by calling DBMS_SESSION.RESET_PACKAGE. MLE language code is evaluated in the context using the user, roles, and schema that are in effect at the time of context creation.

The procedure may raise the ORA-01031 error if the caller does not have sufficient privileges.

117.3.2 DISABLE_CTX_STDERR Procedure

This procedure disables stderr stream of the specified MLE context, so that future writes to stderr are discarded. You need the EXECUTE DYNAMIC MLE privilege to execute this function.

Syntax

```
DBMS_MLE.DISABLE_CTX_STDERR(
      context_handle            IN            context_handle_t);
```

Parameters

Table 117-2 DISABLE_CTX_STDERR Procedure Parameters

Parameter	Description
`context_handle`	The handle to an MLE context in the current session.

Usage Notes

Any output that was buffered so far gets flushed to the pre-existing sink.

The procedure may raise the following errors:

- `ORA-01031`: if the caller does not have sufficient privileges

117.3.3 DISABLE_CTX_STDOUT Procedure

This procedure disables `stdout` stream of the specified MLE context, so that future writes to `stdout` are discarded. You need the `EXECUTE DYNAMIC MLE` privilege to execute this function.

Syntax

```
DBMS_MLE.DISABLE_CTX_STDOUT(
      context_handle            IN            context_handle_t);
```

Parameters

Table 117-3 DISABLE_CTX_STDOUT Procedure Parameters

Parameter	Description
`context_handle`	The handle to an MLE context in the current session.

Usage Notes

Any output that was buffered so far gets flushed to the pre-existing sink.

The procedure may raise the following errors:

- `ORA-01031`: if the caller does not have sufficient privileges

117.3.4 DISABLE_STDERR Procedure

This procedure disables the `stderr` stream of all MLE contexts, so that future writes to `stderr` are discarded. This applies to all existing contexts and contexts created in the future. You need the `EXECUTE DYNAMIC MLE` privilege to execute this function.

Syntax

```
DBMS_MLE.DISABLE_STDERR();
```

Usage Notes

Any output that was buffered so far gets flushed to the pre-existing sink.

The procedure may raise the following errors:

- `ORA-01031`: if the caller does not have sufficient privileges

117.3.5 DISABLE_STDOUT Procedure

This procedure disables the stdout stream of all MLE contexts, so that future writes to `stdout` are discarded. This applies to all existing contexts and contexts created in the future. You need the `EXECUTE DYNAMIC MLE` privilege to execute this function.

Syntax

```
DBMS_MLE.DISABLE_STDOUT();
```

Usage Notes

Any output that was buffered so far gets flushed to the pre-existing sink.

The procedure may raise the following errors:

- `ORA-01031`: if the caller does not have sufficient privileges

117.3.6 DROP_CONTEXT Procedure

This procedure is used to drop an MLE context that was previously created using the `CREATE_CONTEXT` function. After the context is dropped, the context handle is no longer valid and cannot be used anymore. You need the `EXECUTE DYNAMIC MLE` privilege to execute this procedure.

Syntax

```
DBMS_MLE.DROP_CONTEXT(
   context_handle   IN      context_handle_t);
```

Parameters

Table 117-4 DROP_CONTEXT Procedure Parameters

Parameter	Description
`context_handle`	The handle to an MLE context in the current session.

Usage Notes

The procedure may raise `ORA-01031` error if the caller does not have sufficient privileges.

117.3.7 EVAL Procedure

This procedure executes the given MLE language code within the context identified by the context handle.

The evaluated code has access to all previous modifications to the state of the context, including variables defined by code previously evaluated in the context and values exported through `EXPORT_TO_MLE()`. The evaluated code can also import MLE built-in modules such as the MLE SQL driver.

You need the `EXECUTE DYNAMIC MLE` privilege to execute this procedure. It also requires the `EXECUTE` privilege for the given language, for example, `EXECUTE ON JAVASCRIPT`.

Syntax

```
DBMS_MLE.EVAL(
   context_handle   IN         context_handle_t,
   language_id      IN         language_t,
   source           IN         CLOB,
   result           IN OUT     NOCOPY CLOB CHARACTER SET ANY_CS);

DBMS_MLE.EVAL(
   context_handle   IN         context_handle_t,
   language_id      IN         language_t,
   source           IN         VARCHAR2,
   result           IN OUT     NOCOPY CLOB CHARACTER SET ANY_CS);

DBMS_MLE.EVAL(
   context_handle   IN         context_handle_t,
   language_id      IN         language_t,
   source           IN         CLOB);

DBMS_MLE.EVAL(
   context_handle   IN         context_handle_t,
   language_id      IN         language_t,
   source           IN         VARCHAR2);
```

Parameters

Table 117-5 EVAL Procedure Parameters

Parameter	Description
`context_handle`	The handle to an MLE context.
`language_id`	The language of the provided source code. For example, JavaScript.
`source`	The source code to be executed.
`result`	A non-NULL buffer to which the result of the evaluation of the source code is appended.

Usage Notes

The procedure may raise the following errors:

- `ORA-01031`: if the caller does not have sufficient privileges
- `ORA-04108`: if the current container, the current user, or the currently enabled roles are different from those in effect at the time of context creation.

117.3.8 EXPORT_TO_MLE Procedure

This procedure allows you to assign the given value, with appropriate conversion, to the named property in the MLE context. The property is created if it is not already present. You need the `EXECUTE DYNAMIC MLE` privilege to execute this function.

Syntax

```
DBMS_MLE.EXPORT_TO_MLE (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   property_value   IN      BINARY_INTEGER);

DBMS_MLE.EXPORT_TO_MLE (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   property_value   IN      BINARY_DOUBLE);

DBMS_MLE.EXPORT_TO_MLE (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   property_value   IN      BINARY_FLOAT);

DBMS_MLE.EXPORT_TO_MLE (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   property_value   IN      BLOB);

DBMS_MLE.EXPORT_TO_MLE (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   property_value   IN      BOOLEAN);

DBMS_MLE.EXPORT_TO_MLE (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   property_value   IN      CLOB CHARACTER SET ANY_CS);

DBMS_MLE.EXPORT_TO_MLE (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   property_value   IN      DATE);

DBMS_MLE.EXPORT_TO_MLE (
   context_handle   IN      context_handle_t,
   property_name   IN      VARCHAR2,
   property_value   IN      DSINTERVAL_UNCONSTRAINED);

DBMS_MLE.EXPORT_TO_MLE (
   context_handle   IN      context_handle_t,
   property_name   IN      VARCHAR2,
   property_value   IN      NUMBER);

DBMS_MLE.EXPORT_TO_MLE (
   context_handle   IN      context_handle_t,
   property_name   IN      VARCHAR2,
   property_value   IN      TIMESTAMP_TZ_UNCONSTRAINED);

DBMS_MLE.EXPORT_TO_MLE (
```

```
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   property_value   IN      TIMESTAMP_UNCONSTRAINED);

DBMS_MLE.EXPORT_UROWID (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   property_value   IN      UROWID);

DBMS_MLE.EXPORT_TO_MLE (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   property_value   IN      VARCHAR2 CHARACTER SET ANY_CS);

DBMS_MLE.EXPORT_TO_MLE (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   property_value   IN      YMINTERVAL_UNCONSTRAINED);

DBMS_MLE.EXPORT_CHAR (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   property_value   IN      CHAR CHARACTER SET ANY_CS);

DBMS_MLE.EXPORT_RAW (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   property_value   IN      RAW);
```

Parameters

Table 117-6 EXPORT_TO_MLE Procedure Parameters

Parameter	Description
`context_handle`	The handle to an MLE context in the current session.
`property_name`	The name of the variable to be set. If the `property_name` value is `NULL` or an empty string, `ORA-04157` error is thrown.
`property_value`	The value to which the variable should be set.

Usage Notes

The procedure may raise the following errors:

- `ORA-01031`: if the caller does not have sufficient privileges.
- `ORA-04157`: if the value of the passed property_name is `NULL` or an empty string.
- `ORA-04108`: if the current container, the current user, or the currently enabled roles are different from those in effect at the time of context creation.

117.3.9 GET_AVAILABLE_LANGUAGES Function

This function returns the set of available MLE languages.

Syntax

```
DBMS_MLE.GET_AVAILABLE_LANGUAGES()
  RETURN languages_t;
```

Return Values

A set of available MLE languages as a table of language identifiers as they can be used as an argument to `DBMS_MLE.EVAL()`.

117.3.10 GET_CTX_ERROR_STACK Function

This function retrieves the MLE language stack trace for the most recent application error in the given execution context. You need the `EXECUTE DYNAMIC MLE` privilege to execute this function.

Syntax

```
DBMS_MLE.GET_CTX_ERROR_STACK(
      context_handle            IN            context_handle_t)
RETURN error_frames_t;
```

Parameters

Table 117-7 GET_CTX_ERROR_STACK Function Parameters

Parameter	Description
`context_handle`	The handle to an MLE context in the current session.

Return Values

A collection of error stack frames, each of type error_frame_t. An empty collection is returned if there is no error stack to report.

Usage Notes

The Function may raise the following errors:

- `ORA-01031`: if the caller does not have sufficient privileges

117.3.11 IMPORT_FROM_MLE Procedure

This procedure retrieves the value of the named property from the MLE context and converts it to the requested PL/SQL type. You need the `EXECUTE DYNAMIC MLE` privilege to execute this procedure.

Syntax

```
DBMS_MLE.IMPORT_FROM_MLE (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   target           OUT     NOCOPY BINARY_INTEGER);

DBMS_MLE.IMPORT_FROM_MLE (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   target           OUT     NOCOPY BINARY_DOUBLE);

DBMS_MLE.IMPORT_FROM_MLE (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
```

```
   target           OUT     NOCOPY BINARY_FLOAT);

DBMS_MLE.IMPORT_FROM_MLE (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   target           OUT     NOCOPY BLOB);

DBMS_MLE.IMPORT_FROM_MLE (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   target           OUT     NOCOPY BOOLEAN);

DBMS_MLE.IMPORT_FROM_MLE (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   target           OUT     NOCOPY CLOB CHARACTER SET ANY_CS);

DBMS_MLE.IMPORT_FROM_MLE (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   target           OUT     NOCOPY DATE);

DBMS_MLE.IMPORT_FROM_MLE (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   target           OUT     NOCOPY DSINTERVAL_UNCONSTRAINED);

DBMS_MLE.IMPORT_FROM_MLE (
   context_handle   IN      context_handle_t,
   property_name   IN      VARCHAR2,
   target            OUT   NOCOPY NUMBER);

DBMS_MLE.IMPORT_FROM_MLE (
   context_handle   IN      context_handle_t,
   property_name   IN      VARCHAR2,
   target            OUT   NOCOPY TIMESTAMP_TZ_UNCONSTRAINED);

DBMS_MLE.IMPORT_FROM_MLE (
   context_handle   IN      context_handle_t,
   property_name   IN      VARCHAR2,
   target            OUT   NOCOPY TIMESTAMP_UNCONSTRAINED);

DBMS_MLE.IMPORT_UROWID (
   context_handle   IN      context_handle_t,
   property_name   IN      VARCHAR2,
   target            OUT   NOCOPY UROWID);

DBMS_MLE.IMPORT_FROM_MLE (
   context_handle   IN      context_handle_t,
   property_name   IN      VARCHAR2,
   target            OUT   NOCOPY VARCHAR2 CHARACTER SET ANY_CS);

DBMS_MLE.IMPORT_FROM_MLE (
   context_handle   IN      context_handle_t,
   property_name   IN      VARCHAR2,
   target            OUT   NOCOPY YMINTERVAL_UNCONSTRAINED);

DBMS_MLE.IMPORT_CHAR (
   context_handle   IN      context_handle_t,
   property_name   IN      VARCHAR2,
   target            OUT   CHAR CHARACTER SET ANY_CS);
```

```
DBMS_MLE.IMPORT_RAW (
   context_handle   IN      context_handle_t,
   property_name    IN      VARCHAR2,
   target             OUT   RAW);
```

Parameters

Table 117-8 IMPORT_FROM_MLE Procedure Parameters

Parameter	Description
`context_handle`	The handle to an MLE context in the current session.
`property_name`	The name of the property to be retrieved. If the `property_name` is `NULL` or an empty string, `ORA-04157` error is thrown.
`target`	A PL/SQL variable into which the retrieved property is stored.

Usage Notes

The `IMPORT_FROM_MLE` procedure may throw the following exceptions:

- `ORA-01031`: if the caller does not have sufficient privileges.
- `ORA-04108`: if the current container, the current user, or the currently enabled roles are different from those in effect at the time of context creation.
- `ORA-04157`: if the value of the passed property_name is `NULL` or an empty string.
- `ORA-04205`: the value cannot be converted to the target PL/SQL type.
- `ORA-06502`: the buffer of the PL/SQL variable is too small to hold the retrieved value.

117.3.12 SET_CTX_STDERR Procedure

This procedure redirects the `stderr` stream of the MLE context to the given `CLOB`. You need the `EXECUTE DYNAMIC MLE` privilege to execute this function.

Syntax

```
DBMS_MLE.SET_CTX_STDERR(
      context_handle  IN           context_handle_t,
      sink            IN OUT       NOCOPY CLOB CHARACTER SET ANY_CS);
```

Parameters

Table 117-9 SET_CTX_STDERR Procedure Parameters

Parameter	Description
`context_handle`	Handle to an MLE context in the current session.
`sink`	The CLOB sink to redirect stderr to. Providing a `NULL` value will result in `ORA-06530` error.

Usage Notes

Any output that was buffered so far gets flushed to the pre-existing sink before redirecting to the new sink.

The procedure may raise the following errors:

- ORA-01031: if the caller does not have sufficient privileges
- ORA-06530: if the sink is NULL.

117.3.13 SET_CTX_STDERR_TO_DBMS_OUTPUT Procedure

This procedure redirects the stderr stream of the MLE context to DBMS_OUTPUT. You need the EXECUTE DYNAMIC MLE privilege to execute this function.

Syntax

```
DBMS_MLE.SET_CTX_STDERR_TO_DBMS_OUTPUT(
   context_handle      IN      context_handle_t);
```

Parameters

Table 117-10 SET_CTX_STDERR_TO_DBMS_OUTPUT Procedure Parameters

Parameter	Description
context_handle	Handle to an MLE context in the current session.

Usage Notes

Any output that was buffered so far gets flushed to the pre-existing sink before redirecting to DBMS_OUTPUT.

The procedure may raise the following errors:

- ORA-01031: if the caller does not have sufficient privileges

117.3.14 SET_CTX_STDOUT Procedure

This procedure redirects the stdout stream of the MLE context to the given CLOB. You need the EXECUTE DYNAMIC MLE privilege to execute this function.

Syntax

```
DBMS_MLE.SET_CTX_STDOUT(
   context_handle      IN context_handle_t,
   sink                IN OUT NOCOPY CLOB CHARACTER SET ANY_CS);
```

Parameters

Table 117-11 SET_CTX_STDOUT Procedure Parameters

Parameter	Description
context_handle	The handle to an MLE context in the current session.
sink	The CLOB to redirect stdout to. Providing a NULL value will result in ORA-06530 error.

Usage Notes

Any output that was buffered so far gets flushed to the pre-existing sink before redirecting to the new sink.

This procedure may raise the following errors:

- `ORA-01031`: if the caller does not have sufficient privileges
- `ORA-06530`: if the sink is `NULL`.

117.3.15 SET_CTX_STDOUT_TO_DBMS_OUTPUT Procedure

This procedure redirects the `stdout` stream of the MLE context to `DBMS_OUTPUT`. You need the `EXECUTE DYNAMIC MLE` privilege to execute this function.

Syntax

```
DBMS_MLE.SET_CTX_STDOUT_TO_DBMS_OUTPUT(
   context_handle      IN      context_handle_t);
```

Parameters

Table 117-12 SET_CTX_STDOUT_TO_DBMS_OUTPUT Procedure Parameters

Parameter	Description
`context_handle`	The handle to an MLE context in the current session.

Usage Notes

Any output that was buffered so far gets flushed to the pre-existing sink before redirecting to `DBMS_OUTPUT`.

The procedure may raise the following errors:

- `ORA-01031`: if the caller does not have sufficient privileges

117.3.16 SET_STDERR Procedure

This procedure redirects the `stderr` stream of all MLE contexts to the given `CLOB`. This applies to all existing contexts and contexts created in the future. You need the `EXECUTE DYNAMIC MLE` privilege to execute this function.

Syntax

```
DBMS_MLE.SET_STDERR(
      sink            IN OUT       NOCOPY CLOB CHARACTER SET ANY_CS);
```

Parameters

Table 117-13 SET_STDERR Procedure Parameters

Parameter	Description
`sink`	The CLOB to redirect `stdout` to.

Usage Notes

Any output that was buffered so far gets flushed to the pre-existing sink before redirecting to the new sink.

The procedure may raise the following errors:

- `ORA-01031`: if the caller does not have sufficient privileges
- `ORA-06530`: if the sink is `NULL`.

117.3.17 SET_STDERR_TO_DBMS_OUTPUT Procedure

This procedure redirects the `stderr` stream of all MLE contexts to `DBMS_OUTPUT`. This applies to all existing contexts and contexts created in the future. You need the `EXECUTE DYNAMIC MLE` privilege to execute this function.

Syntax

```
DBMS_MLE.SET_STDERR_TO_DBMS_OUTPUT();
```

Usage Notes

Any output that was buffered so far gets flushed to the pre-existing sink before redirecting to `DBMS_OUTPUT`.

The procedure may raise the following errors:

- `ORA-01031`: if the caller does not have sufficient privileges

117.3.18 SET_STDOUT Procedure

This procedure redirects the `stdout` stream of all MLE contexts to the given `CLOB`. This applies to all existing contexts and contexts created in the future. You need the `EXECUTE DYNAMIC MLE` privilege to execute this function.

Syntax

```
DBMS_MLE.SET_STDOUT(
   sink       IN OUT   NOCOPY CLOB CHARACTER SET ANY_CS);
```

Parameters

Table 117-14 SET_STDOUT Procedure Parameters

Parameter	Description
`sink`	The CLOB to redirect stdout to.

Usage Notes

Any output that was buffered so far gets flushed to the pre-existing sink before redirecting to the new sink.

The procedure may raise the following errors:

- `ORA-01031`: if the caller does not have sufficient privileges

- `ORA-06530`: if the sink is `NULL`.

117.3.19 SET_STDOUT_TO_DBMS_OUTPUT Procedure

This procedure redirects the `stdout` stream of all MLE contexts to `DBMS_OUTPUT`. This applies to all existing contexts and contexts created in the future. You need the `EXECUTE DYNAMIC MLE` privilege to execute this function.

Syntax

```
DBMS_MLE.SET_STDOUT_TO_DBMS_OUTPUT();
```

Usage Notes

Any output that was buffered so far gets flushed to the pre-existing sink before redirecting to `DBMS_OUTPUT`.

The procedure may raise the following errors:

- `ORA-01031`: if the caller does not have sufficient privileges

118
DBMS_MONITOR

The DBMS_MONITOR package enables you to use PL/SQL for controlling additional tracing and statistics gathering.

The chapter contains the following topics:

- Summary of DBMS_MONITOR Subprograms

118.1 Summary of DBMS_MONITOR Subprograms

This table lists the DBMS_MONITOR subprograms and briefly describes them.

Table 118-1 DBMS_MONITOR Package Subprograms

Subprogram	Description
CLIENT_ID_STAT_DISABLE Procedure	Disables statistic gathering previously enabled for a given Client Identifier
CLIENT_ID_STAT_ENABLE Procedure	Enables statistic gathering for a given Client Identifier
CLIENT_ID_TRACE_DISABLE Procedure	Disables the trace previously enabled for a given Client Identifier globally for the database
CLIENT_ID_TRACE_ENABLE Procedure	Enables the trace for a given Client Identifier globally for the database
DATABASE_TRACE_DISABLE Procedure	Disables SQL trace for the whole database or a specific instance
DATABASE_TRACE_ENABLE Procedure	Enables SQL trace for the whole database or a specific instance
SERV_MOD_ACT_STAT_DISABLE Procedure	Disables statistic gathering enabled for a given combination of Service Name, MODULE and ACTION
SERV_MOD_ACT_STAT_ENABLE Procedure	Enables statistic gathering for a given combination of Service Name, MODULE and ACTION
SERV_MOD_ACT_TRACE_DISABLE Procedure	Disables the trace for ALL enabled instances for a or a given combination of Service Name, MODULE and ACTION name globally
SERV_MOD_ACT_TRACE_ENABLE Procedure	Enables SQL tracing for a given combination of Service Name, MODULE and ACTION globally unless an instance_name is specified
SESSION_TRACE_DISABLE Procedure	Disables the previously enabled trace for a given database session identifier (SID) on the local instance
SESSION_TRACE_ENABLE Procedure	Enables the trace for a given database session identifier (SID) on the local instance

118.1.1 CLIENT_ID_STAT_DISABLE Procedure

This procedure will disable statistics accumulation for all instances and remove the accumulated results from V$CLIENT_STATS view enabled by the CLIENT_ID_STAT_ENABLE Procedure.

Syntax

```
DBMS_MONITOR.CLIENT_ID_STAT_DISABLE(
   client_id            IN   VARCHAR2);
```

Parameters

Table 118-2 CLIENT_ID_STAT_DISABLE Procedure Parameters

Parameter	Description
client_id	Client Identifier for which statistic aggregation is disabled

Examples

To disable accumulation:

```
EXECUTE DBMS_MONITOR.CLIENT_ID_STAT_DISABLE('janedoe');
```

118.1.2 CLIENT_ID_STAT_ENABLE Procedure

This procedure enables statistic gathering for a given Client Identifier.

Statistics gathering is global for the database and persistent across instance starts and restarts. That is, statistics are enabled for all instances of the same database, including restarts. Statistics are viewable through V$CLIENT_STATS views.

Syntax

```
DBMS_MONITOR.CLIENT_ID_STAT_ENABLE(
   client_id            IN   VARCHAR2);
```

Parameters

Table 118-3 *CLIENT_ID_STAT_ENABLE Procedure Parameters*

Parameter	Description
client_id	Client Identifier for which statistic aggregation is enabled

Examples

To enable statistic accumulation for a client with a given client ID:

```
EXECUTE DBMS_MONITOR.CLIENT_ID_STAT_ENABLE('janedoe');
```

118.1.3 CLIENT_ID_TRACE_DISABLE Procedure

This procedure will disable tracing enabled by the `CLIENT_ID_TRACE_ENABLE` Procedure.

Syntax

```
DBMS_MONITOR.CLIENT_ID_TRACE_DISABLE(
 client_id     IN  VARCHAR2);
```

Parameters

Table 118-4 CLIENT_ID_TRACE_DISABLE Procedure Parameters

Parameter	Description
`client_id`	Client Identifier for which SQL tracing is disabled

Examples

```
EXECUTE DBMS_MONITOR.CLIENT_ID_TRACE_DISABLE ('janedoe');
```

118.1.4 CLIENT_ID_TRACE_ENABLE Procedure

This procedure will enable the trace for a given client identifier globally for the database.

Syntax

```
DBMS_MONITOR.CLIENT_ID_TRACE_ENABLE(
 client_id     IN  VARCHAR2,
 waits         IN  BOOLEAN DEFAULT TRUE,
 binds         IN  BOOLEAN DEFAULT FALSE,
 plan_stat     IN  VARCHAR2 DEFAULT NULL);
```

Parameters

Table 118-5 CLIENT_ID_TRACE_ENABLE Procedure Parameters

Parameter	Description
`client_id`	Database Session Identifier for which SQL tracing is enabled
`waits`	If `TRUE`, wait information is present in the trace
`binds`	If `TRUE`, bind information is present in the trace
`plan_stat`	Frequency at which we dump row source statistics. Value should be `'NEVER'`, `'FIRST_EXECUTION'` (equivalent to `NULL`) or `'ALL_EXECUTIONS'`.

Usage Notes

- The trace will be written to multiple trace files because more than one Oracle shadow process can work on behalf of a given client identifier.
- The tracing is enabled for all instances and persistent across restarts.

Examples

```
EXECUTE DBMS_MONITOR.CLIENT_ID_TRACE_ENABLE('janedoe', TRUE,
FALSE);
```

118.1.5 DATABASE_TRACE_DISABLE Procedure

This procedure disables SQL trace for the whole database or a specific instance.

Syntax

```
DBMS_MONITOR.DATABASE_TRACE_DISABLE(
   instance_name  IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 118-6 DATABASE_TRACE_DISABLE Procedure Parameters

Parameter	Description
instance_name	Disables tracing for the named instance

118.1.6 DATABASE_TRACE_ENABLE Procedure

This procedure enables SQL trace for the whole database or a specific instance.

Syntax

```
DBMS_MONITOR.DATABASE_TRACE_ENABLE(
   waits          IN BOOLEAN DEFAULT TRUE,
   binds          IN BOOLEAN DEFAULT FALSE,
   instance_name  IN VARCHAR2 DEFAULT NULL,
   plan_stat      IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 118-7 DATABASE_TRACE_ENABLE Procedure Parameters

Parameter	Description
waits	If TRUE, wait information will be present in the trace
binds	If TRUE, bind information will be present in the trace
instance_name	If set, restricts tracing to the named instance
plan_stat	Frequency at which we dump row source statistics. Value should be 'NEVER', 'FIRST_EXECUTION' (equivalent to NULL) or 'ALL_EXECUTIONS'.

118.1.7 SERV_MOD_ACT_STAT_DISABLE Procedure

This procedure will disable statistics accumulation and remove the accumulated results from V$SERV_MOD_ACT_STATS view.

Statistics disabling is persistent for the database. That is, service statistics are disabled for instances of the same database (plus dblinks that have been activated as a result of the enable).

Syntax

```
DBMS_MONITOR.SERV_MOD_ACT_STAT_DISABLE(
   service_name    IN VARCHAR2,
   module_name     IN VARCHAR2,
   action_name     IN VARCHAR2 DEFAULT ALL_ACTIONS);
```

Parameters

Table 118-8 SERV_MOD_ACT_STAT_DISABLE Procedure Parameters

Parameter	Description
service_name	Name of the service for which statistic aggregation is disabled
module_name	Name of the MODULE. An additional qualifier for the service. It is a required parameter.
action_name	Name of the ACTION. An additional qualifier for the Service and MODULE name. Omitting the parameter (or supplying ALL_ACTIONS constant) means enabling aggregation for all Actions for a given Service/MODULE combination. In this case, statistics are aggregated on the module level.

Usage Notes

Regarding statistics gathering, when you change the module or action, the change takes effect when the next user call is executed in the session. For example, if a module is set to 'module 1' in a session, and the module is reset to 'module 2' in a user call in the session, then the module remains 'module 1' during this user call. The module is changed to 'module 2' in the next user call in the session.

118.1.8 SERV_MOD_ACT_STAT_ENABLE Procedure

This procedure enables statistic gathering for a given combination of Service Name, MODULE and ACTION.

Calling this procedure enables statistic gathering for a hierarchical combination of Service name, MODULE name, and ACTION name on all instances for the same database. Statistics are accessible by means of the V$SERV_MOD_ACT_STATS view.

Syntax

```
DBMS_MONITOR.SERV_MOD_ACT_STAT_ENABLE(
   service_name    IN VARCHAR2,
   module_name     IN VARCHAR2,
   action_name     IN VARCHAR2 DEFAULT ALL_ACTIONS);
```

Parameters

Table 118-9 SERV_MOD_ACT_STAT_ENABLE Procedure Parameters

Parameter	Description
service_name	Name of the service for which statistic aggregation is enabled
module_name	Name of the MODULE. An additional qualifier for the service. It is a required parameter.
action_name	Name of the ACTION. An additional qualifier for the Service and MODULE name. Omitting the parameter (or supplying ALL_ACTIONS constant) means enabling aggregation for all Actions for a given Service/MODULE combination. In this case, statistics are aggregated on the module level.

Usage Notes

Enabling statistic aggregation for the given combination of Service/Module/Action names is slightly complicated by the fact that the Module/Action values can be empty strings which are indistinguishable from NULLs. For this reason, we adopt the following conventions:

A special constant (unlikely to be a real action names) is defined:

```
ALL_ACTIONS constant VARCHAR2 := '###ALL_ACTIONS';
```

Using ALL_ACTIONS for an action specification means that aggregation is enabled for all actions with a given module name, while using NULL (or empty string) means that aggregation is enabled for an action whose name is an empty string.

Regarding statistics gathering, when you change the module or action, the change takes effect when the next user call is executed in the session. For example, if a module is set to 'module 1' in a session, and the module is reset to 'module 2' in a user call in the session, then the module remains 'module 1' during this user call. The module is changed to 'module 2' in the next user call in the session.

Examples

To enable statistic accumulation for a given combination of Service name and MODULE:

```
EXECUTE DBMS_MONITOR.SERV_MOD_ACT_STAT_ENABLE( 'APPS1','PAYROLL');
```

To enable statistic accumulation for a given combination of Service name, MODULE and ACTION:

```
EXECUTE
DBMS_MONITOR.SERV_MOD_ACT_STAT_ENABLE('APPS1','GLEDGER','DEBIT_ENTRY');
```

If both of the preceding commands are issued, statistics are accumulated as follows:

- For the APPS1 service, because accumulation for each Service Name is the default.
- For all actions in the PAYROLL Module.
- For the DEBIT_ENTRY Action within the GLEDGER Module.

118.1.9 SERV_MOD_ACT_TRACE_DISABLE Procedure

This procedure will disable the trace at ALL enabled instances for a given combination of Service Name, MODULE, and ACTION name globally.

Syntax

```
DBMS_MONITOR.SERV_MOD_ACT_TRACE_DISABLE(
   service_name    IN  VARCHAR2,
   module_name     IN  VARCHAR2,
   action_name     IN  VARCHAR2 DEFAULT ALL_ACTIONS,
   instance_name   IN  VARCHAR2 DEFAULT NULL);
```

Parameters

Table 118-10 SERV_MOD_ACT_TRACE_DISABLE Procedure Parameters

Parameter	Description
service_name	Name of the service for which tracing is disabled.
module_name	Name of the MODULE. An additional qualifier for the service
action_name	Name of the ACTION. An additional qualifier for the Service and MODULE name.
instance_name	If set, this restricts tracing to the named instance_name

Usage Notes

Specifying NULL for the module_name parameter means that statistics will no longer be accumulated for the sessions which do not set the MODULE attribute.

Examples

To enable tracing for a Service named APPS1:

```
EXECUTE DBMS_MONITOR.SERV_MOD_ACT_TRACE_ENABLE('APPS1',
            DBMS_MONITOR.ALL_MODULES,  DBMS_MONITOR.ALL_ACTIONS,TRUE,
FALSE,NULL);
```

To disable tracing specified in the previous step:

```
EXECUTE DBMS_MONITOR.SERV_MOD_ACT_TRACE_DISABLE('APPS1');
```

To enable tracing for a given combination of Service and MODULE (all ACTIONs):

```
EXECUTE DBMS_MONITOR.SERV_MOD_ACT_TRACE_ENABLE('APPS1','PAYROLL',
            DBMS_MONITOR.ALL_ACTIONS,TRUE,FALSE,NULL);
```

To disable tracing specified in the previous step:

```
EXECUTE DBMS_MONITOR.SERV_MOD_ACT_TRACE_DISABLE('APPS1','PAYROLL');
```

118.1.10 SERV_MOD_ACT_TRACE_ENABLE Procedure

This procedure will enable SQL tracing for a given combination of Service Name, MODULE and ACTION globally unless an instance_name is specified.

Syntax

```
DBMS_MONITOR.SERV_MOD_ACT_TRACE_ENABLE(
   service_name    IN VARCHAR2,
   module_name     IN VARCHAR2 DEFAULT ANY_MODULE,
   action_name     IN VARCHAR2 DEFAULT ANY_ACTION,
   waits           IN BOOLEAN DEFAULT TRUE,
   binds           IN BOOLEAN DEFAULT FALSE,
   instance_name   IN VARCHAR2 DEFAULT NULL,
   plan_stat       IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 118-11 SERV_MOD_ACT_TRACE_ENABLE Procedure Parameters

Parameter	Description
service_name	Name of the service for which SQL trace is enabled
module_name	Name of the MODULE for which SQL trace is enabled. An optional additional qualifier for the service. If omitted, SQL trace is enabled or all modules and actions in a given service.
action_name	Name of the ACTION for which SQL trace is enabled. An optional additional qualifier for the Service and MODULE name. If omitted, SQL trace is enabled for all actions in a given module.
waits	If TRUE, wait information is present in the trace
binds	If TRUE, bind information is present in the trace
instance_name	If set, this restricts tracing to the named instance_name
plan_stat	Frequency at which we dump row source statistics. Value should be 'NEVER', 'FIRST_EXECUTION' (equivalent to NULL) or 'ALL_EXECUTIONS'.

Usage Notes

- The procedure enables a trace for a given combination of Service, MODULE and ACTION name. The specification is strictly hierarchical: Service Name or Service Name/MODULE, or Service Name, MODULE, and ACTION name must be specified. Omitting a qualifier behaves like a wild-card, so that not specifying an ACTION means all ACTIONs. Using the ALL_ACTIONS constant achieves the same purpose.
- This tracing is useful when an application MODULE and optionally known ACTION is experiencing poor service levels.
- By default, tracing is enabled globally for the database. The instance_name parameter is provided to restrict tracing to named instances that are known, for example, to exhibit poor service levels.
- Tracing information is present in multiple trace files and you must use the trcsess tool to collect it into a single file.

- Specifying NULL for the module_name parameter means that statistics will be accumulated for the sessions which do not set the MODULE attribute.

Examples

To enable tracing for a Service named APPS1:

```
EXECUTE DBMS_MONITOR.SERV_MOD_ACT_TRACE_ENABLE('APPS1',
            DBMS_MONITOR.ALL_MODULES,   DBMS_MONITOR.ALL_ACTIONS,TRUE,
FALSE,NULL);
```

To enable tracing for a given combination of Service and MODULE (all ACTIONs):

```
EXECUTE DBMS_MONITOR.SERV_MOD_ACT_TRACE_ENABLE('APPS1','PAYROLL',
            DBMS_MONITOR.ALL_ACTIONS,TRUE,FALSE,NULL);
```

118.1.11 SESSION_TRACE_DISABLE Procedure

This procedure will disable the trace for a given database session at the local instance.

Syntax

```
DBMS_MONITOR.SESSION_TRACE_DISABLE(
   session_id      IN     BINARY_INTEGER DEFAULT NULL,
   serial_num      IN     BINARY_INTEGER DEFAULT NULL);
```

Parameters

Table 118-12 SESSION_TRACE_DISABLE Procedure Parameters

Parameter	Description
session_id	Database Session Identifier for which SQL trace is disabled
serial_num	Serial number for this session

Usage Notes

If serial_num is NULL but session_id is specified, a session with a given session_id is no longer traced irrespective of its serial number. If both session_id and serial_num are NULL, the current user session is no longer traced. It is illegal to specify NULL session_id and non-NULL serial_num. In addition, the NULL values are default and can be omitted.

Examples

To enable tracing for a client with a given client session ID:

```
EXECUTE DBMS_MONITOR.SESSION_TRACE_ENABLE(7,4634, TRUE, FALSE);
```

To disable tracing specified in the previous step:

```
EXECUTE DBMS_MONITOR.SESSION_TRACE_DISABLE(7,4634);;
```

118.1.12 SESSION_TRACE_ENABLE Procedure

This procedure enables a SQL trace for the given Session ID on the local instance

Syntax

```
DBMS_MONITOR.SESSION_TRACE_ENABLE(
    session_id   IN  BINARY_INTEGER DEFAULT NULL,
    serial_num   IN  BINARY_INTEGER DEFAULT NULL,
    waits        IN  BOOLEAN DEFAULT TRUE,
    binds        IN  BOOLEAN DEFAULT FALSE,
    plan_stat    IN  VARCHAR2 DEFAULT NULL);
```

Parameters

Table 118-13 SESSION_TRACE_ENABLE Procedure Parameters

Parameter	Description
`session_id`	Client Identifier for which SQL trace is enabled. If omitted (or `NULL`), the user's own session is assumed.
`serial_num`	Serial number for this session. If omitted (or `NULL`), only the session ID is used to determine a session.
`waits`	If `TRUE`, wait information is present in the trace
`binds`	If `TRUE`, bind information is present in the trace
`plan_stat`	Frequency at which we dump row source statistics. Value should be 'NEVER', 'FIRST_EXECUTION' (equivalent to `NULL`) or 'ALL_EXECUTIONS'.

Usage Notes

The procedure enables a trace for a given database session, and is still useful for client/server applications. The trace is enabled only on the instance to which the caller is connected, since database sessions do not span instances. This tracing is strictly local to an instance.

If `serial_num` is `NULL` but `session_id` is specified, a session with a given `session_id` is traced irrespective of its serial number. If both `session_id` and `serial_num` are `NULL`, the current user session is traced. It is illegal to specify `NULL session_id` and non-`NULL serial_num`. In addition, the `NULL` values are default and can be omitted.

Examples

To enable tracing for a client with a given client session ID:

```
EXECUTE DBMS_MONITOR.SESSION_TRACE_ENABLE(7,4634, TRUE, FALSE);
```

To disable tracing specified in the previous step:

```
EXECUTE DBMS_MONITOR.SESSION_TRACE_DISABLE(7,4634);
```

Either

```
EXECUTE DBMS_MONITOR.SESSION_TRACE_ENABLE(5);
```

or

```
EXECUTE DBMS_MONITOR.SESSION_TRACE_ENABLE(5, NULL);
```

traces the session with session ID of 5, while either

```
EXECUTE DBMS_MONITOR.SESSION_TRACE_ENABLE();
```

or

```
EXECUTE DBMS_MONITOR.SESSION_TRACE_ENABLE(NULL, NULL);
```

traces the current user session. Also,

```
EXECUTE DBMS_MONITOR.SESSION_TRACE_ENABLE(NULL, NULL, TRUE, TRUE);
```

traces the current user session including waits and binds. The same can be also expressed using keyword syntax:

```
EXECUTE DBMS_MONITOR.SESSION_TRACE_ENABLE(binds=>TRUE);
```

119
DBMS_MVIEW

DBMS_MVIEW enables you to understand capabilities for materialized views and potential materialized views, including their rewrite availability. It also enables you to refresh materialized views that are not part of the same refresh group and purge logs.

> **Note:**
>
> DBMS_MVIEW is a synonym for DBMS_SNAPSHOT.

> **See Also:**
>
> *Oracle Database Data Warehousing Guide* for more information about using materialized views in a data warehousing environment

This chapter contains the following topics:

- Operational Notes
- Security Model
- Rules and Limits
- Summary of DBMS_MVIEW Subprograms

119.1 DBMS_MVIEW Operational Notes

If a query is less than 256 characters long, you can invoke EXPLAIN_REWRITE using the EXECUTE command from SQL*Plus. Otherwise, the recommended method is to use a PL/SQL BEGIN..END block, as shown in the examples in /rdbms/demo/smxrw.sql.

119.2 DBMS_MVIEW Security Model

The DBMS_MVIEW package consists of a number of materialized view-related subprograms, each of which has different functionality and privilege requirements.

The privilege model is generally based on the invoker's right. Each package subprogram is executed by first checking the privileges against the invoker. If all the required privileges are met, the subprogram will be executed. Otherwise, an insufficient privileges error will be thrown.

119.3 DBMS_MVIEW Rules and Limits

The `DBMS_MVIEW.EXPLAIN_REWRITE` procedure cannot accept queries longer than 32627 characters. These restrictions also apply when passing the defining query of a materialized view to the `DBMS_MVIEW.EXPLAIN_MVIEW` procedure.

119.4 Summary of DBMS_MVIEW Subprograms

This table lists the `DBMS_MVIEW` subprograms and briefly describes them.

Table 119-1 DBMS_MVIEW Package Subprograms

Subprogram	Description
BEGIN_TABLE_REORGANIZATION Procedure	Performs a process to preserve materialized view data needed for refresh
END_TABLE_REORGANIZATION Procedure	Ensures that the materialized view data for the master table is valid and that the master table is in the proper state
ESTIMATE_MVIEW_SIZE Procedure	Estimates the size of a materialized view that you might create, in bytes and rows
EXPLAIN_MVIEW Procedure	Explains what is possible with a materialized view or potential materialized view
EXPLAIN_REWRITE Procedure	Explains why a query failed to rewrite or why the optimizer chose to rewrite a query with a particular materialized view or materialized views
I_AM_A_REFRESH Function	Returns the value of the `I_AM_REFRESH` package state
PMARKER Function	Returns a partition marker from a rowid, and is used for Partition Change Tracking (PCT)
PURGE_DIRECT_LOAD_LOG Procedure	Purges rows from the direct loader log after they are no longer needed by any materialized views (used with data warehousing)
PURGE_LOG Procedure	Purges rows from the materialized view log
PURGE_MVIEW_FROM_LOG Procedure	Purges rows from the materialized view log
REFRESH Procedures	Refreshes one or more materialized views that are not members of the same refresh group
REFRESH_ALL_MVIEWS Procedure	Refreshes all materialized views that do not reflect changes to their master table or master materialized view
REFRESH_DEPENDENT Procedures	Refreshes all table-based materialized views that depend on a specified master table or master materialized view, or list of master tables or master materialized views
REGISTER_MVIEW Procedure	Enables the administration of individual materialized views
UNREGISTER_MVIEW Procedure	Enables the administration of individual materialized views once invoked at a master site or master materialized view site to unregister a materialized view

119.4.1 BEGIN_TABLE_REORGANIZATION Procedure

This procedure performs a process to preserve materialized view data needed for refresh. It must be called before a master table is reorganized.

Syntax

```
DBMS_MVIEW.BEGIN_TABLE_REORGANIZATION (
   tabowner     IN   VARCHAR2,
   tabname      IN   VARCHAR2);
```

Parameters

Table 119-2 BEGIN_TABLE_REORGANIZATION Procedure Parameters

Parameter	Description
tabowner	Owner of the table being reorganized
tabname	Name of the table being reorganized

119.4.2 END_TABLE_REORGANIZATION Procedure

This procedure ensures that the materialized view data for the master table is valid and that the master table is in the proper state. It must be called after a master table is reorganized.

Syntax

```
DBMS_MVIEW.END_TABLE_REORGANIZATION (
   tabowner     IN   VARCHAR2,
   tabname      IN   VARCHAR2);
```

Parameters

Table 119-3 END_TABLE_REORGANIZATION Procedure Parameters

Parameter	Description
tabowner	Owner of the table being reorganized
tabname	Name of the table being reorganized

119.4.3 ESTIMATE_MVIEW_SIZE Procedure

This procedure estimates the size of a materialized view that you might create, in bytes and number of rows.

Syntax

```
DBMS_MVIEW.ESTIMATE_MVIEW_SIZE (
   stmt_id       IN  VARCHAR2,
   select_clause IN  VARCHAR2,
   num_rows      OUT NUMBER,
   num_bytes     OUT NUMBER);
```

Parameters

Table 119-4 ESTIMATE_MVIEW_SIZE Procedure Parameters

Parameter	Description
stmt_id	Arbitrary string used to identify the statement in an EXPLAIN PLAN
select_clause	The SELECT statement to be analyzed
num_rows	Estimated cardinality
num_bytes	Estimated number of bytes

119.4.4 EXPLAIN_MVIEW Procedure

This procedure enables you to learn what is possible with a materialized view or potential materialized view. For example, you can determine if a materialized view is fast refreshable and what types of query rewrite you can perform with a particular materialized view.

Using this procedure is straightforward. You simply call DBMS_MVIEW.EXPLAIN_MVIEW, passing in as parameters the schema and materialized view name for an existing materialized view. Alternatively, you can specify the SELECT string or CREATE MATERIALIZED VIEW statement for a potential materialized view. The materialized view or potential materialized view is then analyzed and the results are written into either a table called MV_CAPABILITIES_TABLE, which is the default, or to an array called MSG_ARRAY.

The procedure is overloaded:

- The first version is for explaining an existing or potential materialized view with output to MV_CAPABILITIES_TABLE.
- The second version is for explaining an existing or potential materialized view with output to a VARRAY.

Syntax

```
DBMS_MVIEW.EXPLAIN_MVIEW (
   mv            IN VARCHAR2,
   statement_id  IN VARCHAR2:= NULL);

DBMS_MVIEW.EXPLAIN_MVIEW (
   mv          IN VARCHAR2,
   msg_array   OUT SYS.ExplainMVArrayType);
```

Parameters

Table 119-5 EXPLAIN_MVIEW Procedure Parameters

Parameter	Description
mv	The name of an existing materialized view (optionally qualified with the owner name separated by a ".") or a SELECT statement or a CREATE MATERIALIZED VIEW statement for a potential materialized view.

Table 119-5 (Cont.) EXPLAIN_MVIEW Procedure Parameters

Parameter	Description
statement_id	A client-supplied unique identifier to associate output rows with specific invocations of EXPLAIN_MVIEW
msg_array	The PL/SQL VARRAY that receives the output. Use this parameter to direct EXPLAIN_MVIEW's output to a PL/SQL VARRAY rather than MV_CAPABILITIES_TABLE.

Usage Notes

You must run the utlxmv.sql script to create MV_CAPABILITIES_TABLE in the current schema prior to calling EXPLAIN_MVIEW except when you direct output to a VARRAY. The script is found in the ADMIN directory.

119.4.5 EXPLAIN_REWRITE Procedure

This procedure enables you to learn why a query failed to rewrite, or, if it rewrites, which materialized views will be used.

Using the results from the procedure, you can take the appropriate action needed to make a query rewrite if at all possible. The query specified in the EXPLAIN_REWRITE statement is never actually executed.

A demo file, xrwutl.sql, is available to help format the output from EXPLAIN_REWRITE.

Syntax

You can obtain the output from DBMS_MVIEW.EXPLAIN_REWRITE in two ways. The first is to use a table, while the second is to create a VARRAY. The following shows the basic syntax for using an output table:

```
DBMS_MVIEW.EXPLAIN_REWRITE (
    query           VARCHAR2,
    mv              VARCHAR2(30),
    statement_id    VARCHAR2(30));
```

You can create an output table called REWRITE_TABLE by executing the utlxrw.sql script.

The query parameter is a text string representing the SQL query. The parameter, mv, is a fully qualified materialized view name in the form of schema.mv. This is an optional parameter. When it is not specified, EXPLAIN_REWRITE returns any relevant messages regarding all the materialized views considered for rewriting the given query. When schema is omitted and only mv is specified, EXPLAIN_REWRITE looks for the materialized view in the current schema.

If you want to direct the output of EXPLAIN_REWRITE to a VARRAY instead of a table, you should call the procedure as follows:

```
DBMS_MVIEW.EXPLAIN_REWRITE (
    query           [VARCHAR2 | CLOB],
    mv               VARCHAR2(30),
    output_array     SYS.RewriteArrayType);
```

Note that if the query is less than 256 characters long, EXPLAIN_REWRITE can be easily invoked with the EXECUTE command from SQL*Plus. Otherwise, the recommended method is to use a PL/SQL BEGIN... END block, as shown in the examples in /rdbms/demo/smxrw*.

You can also use EXPLAIN_REWRITE with multiple materialized views, in which case the syntax will be the same as with a single materialized view, except that the materialized views are specified by a comma-delimited string. For example, to find out whether a given set of materialized views mv1, mv2, and mv3 could be used to rewrite the query, query_txt, and, if not, why not, use EXPLAIN_REWRITE as follows:

```
DBMS_MVIEW.EXPLAIN_REWRITE(query_txt, 'mv1, mv2, mv3')
```

See *Oracle Database Data Warehousing Guide* for more information on using the EXPLAIN_REWRITE procedure.

Parameters

Table 119-6 EXPLAIN_REWRITE Procedure Parameters

Parameter	Description
query	SQL SELECT statement to be explained
mv	The fully qualified name of an existing materialized view in the form of SCHEMA.MV. For multiple materialized views, you can provide a comma-delimited list of names.
statement_id	A client-supplied unique identifier to distinguish output messages
msg_array	The PL/SQL VARRAY that receives the output. Use this parameter to direct EXPLAIN_REWRITE's output to a PL/SQL VARRAY.

Usage Notes

To obtain the output into a table, you must run the utlxrw.sql script before calling EXPLAIN_REWRITE. This script creates a table named REWRITE_TABLE in the current schema.

119.4.6 I_AM_A_REFRESH Function

This function returns the value of the I_AM_REFRESH package state.

Syntax

```
DBMS_MVIEW.I_AM_A_REFRESH
   RETURN BOOLEAN;
```

Return Values

A return value of true indicates that all local replication triggers for materialized views are effectively disabled in this session because each replication trigger first checks this state. A return value of false indicates that these triggers are enabled.

119.4.7 PMARKER Function

This function returns a partition marker from a rowid. It is used for Partition Change Tracking (PCT).

Syntax

```
DBMS_MVIEW.PMARKER(
   rid IN ROWID)
 RETURN NUMBER;
```

Parameters

Table 119-7 PMARKER Function Parameters

Parameter	Description
rid	The rowid of a row entry in a master table

119.4.8 PURGE_DIRECT_LOAD_LOG Procedure

This procedure removes entries from the direct loader log after they are no longer needed for any known materialized view. This procedure usually is used in environments using Oracle's data warehousing technology.

Syntax

```
DBMS_MVIEW.PURGE_DIRECT_LOAD_LOG();
```

119.4.9 PURGE_LOG Procedure

This procedure purges rows from the materialized view log.

Syntax

```
DBMS_MVIEW.PURGE_LOG (
   master        IN   VARCHAR2,
   num           IN   BINARY_INTEGER := 1,
   flag          IN   VARCHAR2       := 'NOP');
```

Parameters

Table 119-8 PURGE_LOG Procedure Parameters

Parameter	Description
master	Name of the master table or master materialized view.

Table 119-8 (Cont.) PURGE_LOG Procedure Parameters

Parameter	Description

num	Number of least recently refreshed materialized views whose rows you want to remove from materialized view log. For example, the following statement deletes rows needed to refresh the two least recently refreshed materialized views:
	`DBMS_MVIEW.PURGE_LOG('master_table', 2);`
	To delete all rows in the materialized view log, indicate a high number of materialized views to disregard, as in this example:
	`DBMS_MVIEW.PURGE_LOG('master_table',9999);`
	This statement completely purges the materialized view log that corresponds to `master_table` if fewer than 9999 materialized views are based on `master_table`. A simple materialized view whose rows have been purged from the materialized view log must be completely refreshed the next time it is refreshed.

flag	Specify `delete` to guarantee that rows are deleted from the materialized view log for at least one materialized view. This parameter can override the setting for the parameter `num`. For example, the following statement deletes rows from the materialized view log that has dependency rows in the least recently refreshed materialized view: `DBMS_MVIEW.PURGE_LOG('master_table',1,'delete');`

119.4.10 PURGE_MVIEW_FROM_LOG Procedure

This procedure is called on the master site or master materialized view site to delete the rows in materialized view refresh related data dictionary tables maintained at the master for the specified materialized view identified by `mview_id` or the combination of `mviewowner`, `mviewname`, and `mviewsite`.

If the materialized view specified is the oldest materialized view to have refreshed from any of the master tables or master materialized views, then the materialized view log is also purged. This procedure does not unregister the materialized view.

Syntax

```
DBMS_MVIEW.PURGE_MVIEW_FROM_LOG (
   mview_id       IN   BINARY_INTEGER);

DBMS_MVIEW.PURGE_MVIEW_FROM_LOG (
   mviewowner     IN   VARCHAR2,
   mviewname      IN   VARCHAR2,
   mviewsite      IN   VARCHAR2);
```

> **Note:**
>
> This procedure is overloaded. The parameter `mview_id` is mutually exclusive with the three remaining parameters: `mviewowner`, `mviewname`, and `mviewsite`.

Parameters

Table 119-9 PURGE_MVIEW_FROM_LOG Procedure Parameters

Parameter	Description
mview_id	If you want to execute this procedure based on the identification of the target materialized view, specify the materialized view identification using the mview_id parameter. Query the DBA_BASE_TABLE_MVIEWS view at the materialized view log site for a listing of materialized view IDs. Executing this procedure based on the materialized view identification is useful if the target materialized view is not listed in the list of registered materialized views (DBA_REGISTERED_MVIEWS).
mviewowner	If you do not specify an mview_id, enter the owner of the target materialized view using the mviewowner parameter. Query the DBA_REGISTERED_MVIEWS view at the materialized view log site to view the materialized view owners.
mviewname	If you do not specify an mview_id, enter the name of the target materialized view using the mviewname parameter. Query the DBA_REGISTERED_MVIEWS view at the materialized view log site to view the materialized view names.
mviewsite	If you do not specify an mview_id, enter the site of the target materialized view using the mviewsite parameter. Query the DBA_REGISTERED_MVIEWS view at the materialized view log site to view the materialized view sites.

Usage Notes

If there is an error while purging one of the materialized view logs, the successful purge operations of the previous materialized view logs are not rolled back. This is to minimize the size of the materialized view logs. In case of an error, this procedure can be invoked again until all the materialized view logs are purged.

119.4.11 REFRESH Procedures

This procedure refreshes a list of materialized views.

Syntax

```
DBMS_MVIEW.REFRESH (
   { list                 IN     VARCHAR2,
   | tab                  IN     DBMS_UTILITY.UNCL_ARRAY,}
   method                 IN     VARCHAR2       := NULL,
   rollback_seg           IN     VARCHAR2       := NULL,
   push_deferred_rpc      IN     BOOLEAN        := true,
   refresh_after_errors   IN     BOOLEAN        := false,
   purge_option           IN     BINARY_INTEGER := 1,
   parallelism            IN     BINARY_INTEGER := 0,
   heap_size              IN     BINARY_INTEGER := 0,
   atomic_refresh         IN     BOOLEAN        := true,
   nested                 IN     BOOLEAN        := false,
   out_of_place           IN     BOOLEAN        := false,
   skip_ext_data             IN     BOOLEAN        := false);
```

> **Note:**
>
> This procedure is overloaded. The `list` and `tab` parameters are mutually exclusive.

Parameters

Table 119-10 REFRESH Procedure Parameters

Parameter	Description
`list | tab`	Comma-delimited list of materialized views that you want to refresh. (Synonyms are not supported.) These materialized views can be located in different schemas and have different master tables or master materialized views. However, all of the listed materialized views must be in your local database. Alternatively, you may pass in a PL/SQL index-by table of type `DBMS_UTILITY.UNCL_ARRAY`, where each element is the name of a materialized view.
`method`	A string of refresh methods indicating how to refresh the listed materialized views. An `f` indicates fast refresh, `?` indicates force refresh, `C` or `c` indicates complete refresh, and `A` or `a` indicates always refresh. `A` and `C` are equivalent. `P` or `p` refreshes by recomputing the rows in the materialized view affected by changed partitions in the detail tables. If a materialized view does not have a corresponding refresh method (that is, if more materialized views are specified than refresh methods), then that materialized view is refreshed according to its default refresh method. For example, consider the following `EXECUTE` statement within SQL*Plus: `DBMS_MVIEW.REFRESH ('countries_mv,regions_mv,hr.employees_mv','cf');` This statement performs a complete refresh of the `countries_mv` materialized view, a fast refresh of the `regions_mv` materialized view, and a default refresh of the `hr.employees` materialized view.
`rollback_seg`	Name of the materialized view site rollback segment to use while refreshing materialized views
`push_deferred_rpc`	Used by updatable materialized views only. Set this parameter to `true` if you want to push changes from the materialized view to its associated master tables or master materialized views before refreshing the materialized view. Otherwise, these changes may appear to be temporarily lost.
`refresh_after_errors`	If this parameter is `true`, an updatable materialized view continues to refresh even if there are outstanding conflicts logged in the `DEFERROR` view for the materialized view's master table or master materialized view. If this parameter is `true` and `atomic_refresh` is `false`, this procedure continues to refresh other materialized views if it fails while refreshing a materialized view.

Table 119-10 (Cont.) REFRESH Procedure Parameters

Parameter	Description
purge_option	If you are using the parallel propagation mechanism (in other words, parallelism is set to 1 or greater), 0 means do not purge, 1 means lazy purge, and 2 means aggressive purge. In most cases, lazy purge is the optimal setting. Set purge to aggressive to trim the queue if multiple master replication groups are pushed to different target sites, and updates to one or more replication groups are infrequent and infrequently pushed. If all replication groups are infrequently updated and pushed, then set this parameter to 0 and occasionally execute PUSH with this parameter set to 2 to reduce the queue.
parallelism	0 specifies serial propagation. *n* > 1 specifies parallel propagation with *n* parallel processes. 1 specifies parallel propagation using only one parallel process.
heap_size	Maximum number of transactions to be examined simultaneously for parallel propagation scheduling. Oracle automatically calculates the default setting for optimal performance. Note**:** Do not set this parameter unless directed to do so by Oracle Support Services.
atomic_refresh	If this parameter is set to true, then the list of materialized views is refreshed in a single transaction. All of the refreshed materialized views are updated to a single point in time. If the refresh fails for any of the materialized views, none of the materialized views are updated. If this parameter is set to false, then each of the materialized views is refreshed non-atomically in separate transactions. As part of complete refresh, if truncate is used (non-atomic refresh), unique index rebuild is executed. INDEX REBUILD automatically computes statistics. Thus, statistics are updated for truncated tables.
nested	If true, then perform nested refresh operations for the specified set of materialized views. Nested refresh operations refresh all the depending materialized views and the specified set of materialized views based on a dependency order to ensure the nested materialized views are truly fresh with respect to the underlying base tables.
out_of_place	If true, then it performs an out-of-place refresh. The default is false. This parameter uses the four methods of refresh (F, P, C, ?). So, for example, if you specify F and out_of_place = true, then an out-of-place fast refresh will be attempted. Similarly, if you specify P and out_of_place = true, then out-of-place PCT refresh will be attempted.
skip_ext_data	Provides you an option to skip the MV data refresh corresponding to the external partitions.

119.4.12 REFRESH_ALL_MVIEWS Procedure

This procedure refreshes all materialized views that have certain properties

All materialized views with the following properties are refreshed:

- The materialized view has not been refreshed since the most recent change to a master table or master materialized view on which it depends.
- The materialized view and all of the master tables or master materialized views on which it depends are local.

- The materialized view is in the view DBA_MVIEWS.

This procedure is intended for use with data warehouses.

Syntax

```
DBMS_MVIEW.REFRESH_ALL_MVIEWS (
   number_of_failures     OUT   BINARY_INTEGER,
   method                 IN    VARCHAR2         := NULL,
   rollback_seg           IN    VARCHAR2         := NULL,
   refresh_after_errors   IN    BOOLEAN          := false,
   atomic_refresh         IN    BOOLEAN          := true,
   out_of_place           IN    BOOLEAN          := false);
```

Parameters

Table 119-11 REFRESH_ALL_MVIEWS Procedure Parameters

Parameter	Description
number_of_failures	Returns the number of failures that occurred during processing
method	A single refresh method indicating the type of refresh to perform for each materialized view that is refreshed. F or f indicates fast refresh, ? indicates force refresh, C or c indicates complete refresh, and A or a indicates always refresh. A and C are equivalent. If no method is specified, a materialized view is refreshed according to its default refresh method. P or p refreshes by recomputing the rows in the materialized view affected by changed partitions in the detail tables.
rollback_seg	Name of the materialized view site rollback segment to use while refreshing materialized views
refresh_after_errors	If this parameter is true, an updatable materialized view continues to refresh even if there are outstanding conflicts logged in the DEFERROR view for the materialized view's master table or master materialized view. If this parameter is true and atomic_refresh is false, this procedure continues to refresh other materialized views if it fails while refreshing a materialized view.
atomic_refresh	If this parameter is set to true, then the refreshed materialized views are refreshed in a single transaction. All of the refreshed materialized views are updated to a single point in time. If the refresh fails for any of the materialized views, none of the materialized views are updated. If this parameter is set to false, then each of the materialized views is refreshed non-atomically in separate transactions.
out_of_place	If true, then it performs an out-of-place refresh. The default is false. This parameter uses the four methods of refresh (F, P, C, ?). So, for example, if you specify F and out_of_place = true, then an out-of-place fast refresh will be attempted. Similarly, if you specify P and out_of_place = true, then out-of-place PCT refresh will be attempted.

119.4.13 REFRESH_DEPENDENT Procedures

This procedure refreshes all materialized views that have certain properties.

Materialized views with the following properties are refreshed:

- The materialized view depends on a master table or master materialized view in the list of specified masters.
- The materialized view has not been refreshed since the most recent change to a master table or master materialized view on which it depends.
- The materialized view and all of the master tables or master materialized views on which it depends are local.
- The materialized view is in the view `DBA_MVIEWS`.

This procedure is intended for use with data warehouses.

Syntax

```
DBMS_MVIEW.REFRESH_DEPENDENT (
   number_of_failures     OUT    BINARY_INTEGER,
   { list                 IN     VARCHAR2,
   | tab                  IN     DBMS_UTILITY.UNCL_ARRAY,}
   method                 IN     VARCHAR2    := NULL,
   rollback_seg           IN     VARCHAR2    := NULL,
   refresh_after_errors   IN     BOOLEAN     := false,
   atomic_refresh         IN     BOOLEAN     := true,
   nested                 IN     BOOLEAN     := false,
   out_of_place           IN     BOOLEAN     := false);
```

> **Note:**
>
> This procedure is overloaded. The `list` and `tab` parameters are mutually exclusive.

Parameters

Table 119-12 REFRESH_DEPENDENT Procedure Parameters

Parameter	Description
`number_of_failures`	Returns the number of failures that occurred during processing
`list | tab`	Comma-delimited list of master tables or master materialized views on which materialized views can depend. (Synonyms are not supported.) These tables and the materialized views that depend on them can be located in different schemas. However, all of the tables and materialized views must be in your local database. Alternatively, you may pass in a PL/SQL index-by table of type `DBMS_UTILITY.UNCL_ARRAY`, where each element is the name of a table.

Table 119-12 (Cont.) REFRESH_DEPENDENT Procedure Parameters

Parameter	Description
method	A string of refresh methods indicating how to refresh the dependent materialized views. All of the materialized views that depend on a particular table are refreshed according to the refresh method associated with that table. F or f indicates fast refresh, ? indicates force refresh, C or c indicates complete refresh, and A or a indicates always refresh. A and C are equivalent. P or p refreshes by recomputing the rows in the materialized view affected by changed partitions in the detail tables. If a table does not have a corresponding refresh method (that is, if more tables are specified than refresh methods), then any materialized view that depends on that table is refreshed according to its default refresh method. For example, the following EXECUTE statement within SQL*Plus: `DBMS_MVIEW.REFRESH_DEPENDENT ('employees,deptartments,hr.regions','cf');` performs a complete refresh of the materialized views that depend on the employees table, a fast refresh of the materialized views that depend on the departments table, and a default refresh of the materialized views that depend on the hr.regions table.
rollback_seg	Name of the materialized view site rollback segment to use while refreshing materialized views
refresh_after_errors	If this parameter is true, an updatable materialized view continues to refresh even if there are outstanding conflicts logged in the DEFERROR view for the materialized view's master table or master materialized view. If this parameter is true and atomic_refresh is false, this procedure continues to refresh other materialized views if it fails while refreshing a materialized view.
atomic_refresh	If this parameter is set to true, then the refreshed materialized views are refreshed in a single transaction. All of the refreshed materialized views are updated to a single point in time. If the refresh fails for any of the materialized views, none of the materialized views are updated. If this parameter is set to false, then each of the materialized views is refreshed non-atomically in separate transactions.
nested	If true, then perform nested refresh operations for the specified set of tables. Nested refresh operations refresh all the depending materialized views of the specified set of tables based on a dependency order to ensure the nested materialized views are truly fresh with respect to the underlying base tables.
out_of_place	If true, then it performs an out-of-place refresh. The default is false. This parameter uses the four methods of refresh (F, P, C, ?). So, for example, if you specify F and out_of_place = true, then an out-of-place fast refresh will be attempted. Similarly, if you specify P and out_of_place = true, then out-of-place PCT refresh will be attempted.

119.4.14 REGISTER_MVIEW Procedure

This procedure enables the administration of individual materialized views. It is invoked at a master site or master materialized view site to register a materialized view.

Note that, typically, a materialized view is registered automatically during materialized view creation. You should only run this procedure to manually register a materialized view if the automatic registration failed or if the registration information was deleted.

Syntax

```
DBMS_MVIEW.REGISTER_MVIEW (
   mviewowner  IN   VARCHAR2,
   mviewname   IN   VARCHAR2,
   mviewsite   IN   VARCHAR2,
   mview_id    IN   DATE | BINARY_INTEGER,
   flag        IN   BINARY_INTEGER,
   qry_txt     IN   VARCHAR2,
   rep_type    IN   BINARY_INTEGER := DBMS_MVIEW.REG_UNKNOWN);
```

Parameters

Table 119-13 REGISTER_MVIEW Procedure Parameters

Parameter	Description
`mviewowner`	Owner of the materialized view.
`mviewname`	Name of the materialized view.
`mviewsite`	Name of the materialized view site for a materialized view registering at an Oracle database version 8.x and higher master site or master materialized view site. This name should not contain any double quotes.
`mview_id`	The identification number of the materialized view. Specify an Oracle database version 8.x and higher materialized view as a `BINARY_INTEGER`. Specify an Oracle database version 7 materialized view registering at an Oracle database version 8.x and higher master sites or master materialized view sites as a `DATE`.
`flag`	A constant that describes the properties of the materialized view being registered. Valid constants that can be assigned include the following: `DBMS_MVIEW.REG_ROWID_MVIEW` for a rowid materialized view `DBMS_MVIEW.REG_PRIMARY_KEY_MVIEW` for a primary key materialized view `DBMS_MVIEW.REG_OBJECT_ID_MVIEW` for an object id materialized view `DBMS_MVIEW.REG_FAST_REFRESHABLE_MVIEW` for a materialized view that can be fast refreshed `DBMS_MVIEW.REG_UPDATABLE_MVIEW` for a materialized view that is updatable A materialized view can have more than one of these properties. In this case, use the plus sign (+) to specify more than one property. For example, if a primary key materialized view can be fast refreshed, you can enter the following for this parameter: `DBMS_MVIEW.REG_PRIMARY_KEY_MVIEW + DBMS_MVIEW.REG_FAST_REFRESHABLE_MVIEW` You can determine the properties of a materialized view by querying the `ALL_MVIEWS` data dictionary view.
`qry_txt`	The first 32,000 bytes of the materialized view definition query.

Table 119-13 (Cont.) REGISTER_MVIEW Procedure Parameters

Parameter	Description
rep_type	Version of the materialized view. Valid constants that can be assigned include the following: DBMS_MVIEW.REG_V7_SNAPSHOT if the materialized view is at an Oracle database version 7 site • DBMS_MVIEW.REG_V8_SNAPSHOT reg_repapi_snapshot if the materialized view is at an Oracle database version 8.x or higher site DBMS_MVIEW.REG_UNKNOWN (the default) if you do not know whether the materialized view is at an Oracle database version 7 site or an Oracle database version 8.x (or higher) site

Usage Notes

This procedure is invoked at the master site or master materialized view site by a remote materialized view site using a remote procedure call. If REGISTER_MVIEW is called multiple times with the same mviewowner, mviewname, and mviewsite, then the most recent values for mview_id, flag, and qry_txt are stored. If a query exceeds the maximum VARCHAR2 size, then qry_txt contains the first 32000 characters of the query and the remainder is truncated. When invoked manually, the value of mview_id must be looked up in the materialized view data dictionary views by the person who calls the procedure.

119.4.15 UNREGISTER_MVIEW Procedure

This procedure enables the administration of individual materialized views. It is invoked at a master site or master materialized view site to unregister a materialized view.

Syntax

```
DBMS_MVIEW.UNREGISTER_MVIEW (
   mviewowner      IN   VARCHAR2,
   mviewname       IN   VARCHAR2,
   mviewsite       IN   VARCHAR2);
```

Parameters

Table 119-14 UNREGISTER_MVIEW Procedure Parameters

Parameters	Description
mviewowner	Owner of the materialized view
mviewname	Name of the materialized view
mviewsite	Name of the materialized view site

120
DBMS_MVIEW_STATS

DBMS_MVIEW_STATS package provides an interface to manage the collection and retention of statistics for materialized view refresh operations.

> **See Also:**
>
> *Oracle Database Data Warehousing Guide* for information about managing and using materialized view refresh statistics

This chapter contains the following topics:

- DBMS_MVIEW_STATS Overview
- DBMS_MVIEW_STATS Security Model
- Summary of DBMS_MVIEW_STATS Subprograms

120.1 DBMS_MVIEW_STATS Overview

You can use the procedures contained in the DBMS_MVIEW_STATS package to manage the collection and retention of statistics for materialized view refresh operations. This includes the level and granularity at which these statistics are collected and the duration for which they are retained in the database.

You can also set database level system defaults for the parameters that control statistics collection.

120.2 DBMS_MVIEW_STATS Security Model

Refer to the Usage Notes section in each subprogram for information about the privileges required to use the subprogram.

120.3 Summary of DBMS_MVIEW_STATS Subprograms

This table lists the DBMS_MVIEW_STATS subprograms and briefly describes them.

Table 120-1 DBMS_MVIEW_STATS Package Subprograms

Subprogram	Description
PURGE_REFRESH_STATS Procedure	Purges the statistics of materialized view refresh operations that are older than the specified retention period.

Table 120-1 (Cont.) DBMS_MVIEW_STATS Package Subprograms

Subprogram	Description
SET_MVREF_STATS_PARAMS Procedure	Sets the values of parameters that define the collection level and retention period for materialized view refresh statistics. You can set the values either at the database level or for individual materialized views.
SET_SYSTEM_DEFAULT Procedure	Sets the system default value of a refresh statistics parameter. The two refresh statistics parameters are collection level and the retention period.

120.3.1 PURGE_REFRESH_STATS Procedure

This procedure purges refresh statistics that are older than the specified retention period for the specified materialized views.

This procedure forces a purge of refresh statistics without altering the retention period defined for the specified materialized views.

Syntax

```
DBMS_MVIEW_STATS.PURGE_REFRESH_STATS (
        mv_list                 IN      VARACHAR2,
        retention_period        IN      NUMBER);
```

Parameters

Table 120-2 PURGE_REFRESH_STATS Procedure Parameters

Parameter	Description
`mv_list`	The fully-qualified name of an existing materialized view in the form of `schema_name.mv_name`. Use a comma-separated list to specify multiple materialized views. Specify `NULL` to purge materialized view refresh statistics for all materialized views in the database.
`retention_period`	The number of days for which refresh statistics must be preserved in the data dictionary. Statistics for materialized view refresh operations that are older than the retention period are purged from the data dictionary. The retention period specified in this procedure overrides the retention period that may have been set previously either at the database level or for specified materialized views. Specify `NULL` to use the purging policy defined by the automatic statistics purge. Specify –1 to purge all refresh statistics.

Usage Notes

To invoke this procedure, you need either the `SYSDBA` privilege or privileges on every materialized view that is specified in `mv_list`.

120.3.2 SET_MVREF_STATS_PARAMS Procedure

This procedure sets the collection level and retention period for materialized view refresh statistics. You can set these properties either for individual materialized views or for all materialized views in the database.

Syntax

```
DBMS_MVIEW_STATS.SET_MVREF_STATS_PARAMS (
        mv_list            IN    VARACHAR2,
        collection_level   IN    VARCHAR2 DEFAULT NULL,
        retention_period   IN    NUMBER DEFAULT NULL);
```

Parameters

Table 120-3 SET_MVREF_STATS_PARAMS Procedure Parameters

Parameter	Description
`mv_list`	The fully-qualified name of an existing materialized view in the form of `schema_name.mv_name`. Use a comma-separated list to specify multiple materialized views. Specify `NULL` to set properties for all existing materialized views in the database.
`collection_level`	Specifies the level of detail used when collecting refresh statistics for the materialized views specified in `mv_list`. Set one of the following values for `collection_level`: • NONE: No materialized view refresh statistics are collected. • TYPICAL: Only basic refresh statistics are collected and stored for the materialized views specified in `mv_list`. • ADVANCED: Detailed refresh statistics are collected and stored for materialized view specified in `mv_list`. If this parameter is set to `NULL`, then the system default value for `collection_level` (set using `SET_SYSTEM_DEFAULT`) is used.
`retention_period`	Specifies the retention period, in days, for the refresh statistics of the materialized views specified in `mv_list`. Statistics that are older than the retention period are automatically purged from the data dictionary. Valid values are between 1 and 1365000. If this parameter is set to `NULL`, then the system default value for `retention_period` (set using `SET_SYSTEM_DEAFULT`) is used. Set `retention_period` to `-1` to specify that refresh statistics for the materialized views in `mv_list` must never be purged.

Usage Notes

To set the collection level or retention period of one or more materialized views, you must have privileges on those materialized views. To set the collection level or retention period for all materialized views in the database, you must have either the `SYSDBA` privilege or privileges on every materialized view in the database.

To set the system-level default values for statistics collection level and retention period, use the `SET_SYSTEM_DEAFULT` procedure.

Use the DBA_MVREF_STATS_PARAMS view to determine the currently-set retention period and collection level for materialized view statistics collection.

To disable refresh statistics collection for all materialized views in the database, use the following:

```
DBMS_MVIEW_STATS.SET_MVREF_STATS_PARAMS (NULL, 'NONE', NULL);
```

Note that the parameters set using SET_MVREF_STATS_PARAMS only affect materialized views that exist in the database at the time the procedure is run. Any new materialized views created after this procedure is run will use the system default values for collection_level and retention_period.

120.3.3 SET_SYSTEM_DEFAULT Procedure

This procedure sets system-wide defaults that manage the collection and retention of materialized view refresh statistics. All newly-created materialized views use these defaults until the parameters are reset explicitly using the SET_MVREF_STATS_PARAMS procedure.

Syntax

```
DBMS_MVIEW_STATS.SET_SYSTEM_DEFAULT (
        parameter_name         IN   VARCHAR2,
        value              IN   VARCHAR2 DEFAULT NULL);
```

Parameters

Table 120-4 SET_SYSTEM_DEFAULT Procedure Parameters

Parameter	Description
parameter_name	The name of the materialized view refresh statistics parameter whose system default value is being set. The parameters that can be set are: • COLLECTION_LEVEL: Specifies the level of detail for collecting materialized view refresh statistics. • RETENTION_PERIOD: Specifies the duration, in days, for which refresh statistics are retained in the data dictionary
value	The value of the materialized view refresh statistics parameter. The valid values for COLLECTION_LEVEL are: • NONE: No refresh statistics are collected for the refresh operation. • TYPICAL: Only basic refresh statistics are collected for the refresh operation. This is the default setting. • ADVANCED: Detailed refresh statistics are collected for the refresh operation. The valid values for RETENTION_PERIOD are: • -1 • Numbers between 1 and 1365000 The default value for retention_period is 31. If you specify NULL for any of the parameters, then the system default setting for that parameter is used.

Usage Notes

You must have SYSDBA privilege to invoke this procedure.

Use the DBA_MVREF_STATS_SYS_DEFAULTS view to display the current default settings for materialized view refresh statistics collection.

121
DBMS_NETWORK_ACL_ADMIN

The DBMS_NETWORK_ACL_ADMIN package provides the interface to administer the network Access Control List (ACL).

The chapter contains the following topics:

- Overview
- Deprecated Subprograms
- Security Model
- Constants
- Exceptions
- Examples
- Summary of DBMS_NETWORK_ACL_ADMIN Subprograms

> **See Also:**
>
> For more information, see "Managing Fine-grained Access to External Network Services" in *Oracle Database Security Guide*

121.1 DBMS_NETWORK_ACL_ADMIN Overview

The DBMS_NETWORK_ACL_ADMIN package provides the interface to administer the network access control lists (ACL).

ACLs are used to control access by users to external network services and resources from the database through PL/SQL network utility packages including UTL_TCP , UTL_HTTP , UTL_SMTP and UTL_INADDR .

121.2 DBMS_NETWORK_ACL_ADMIN Deprecated Subprograms

Oracle recommends that you do not use deprecated subprograms in new applications. Support for deprecated features is for backward compatibility only

The following subprograms are deprecated with release Oracle Database 12*c*:

- ADD_PRIVILEGE Procedure
- ASSIGN_ACL Procedure
- ASSIGN_WALLET_ACL Procedure
- CHECK_PRIVILEGE Function

- CHECK_PRIVILEGE_ACLID Function
- CREATE_ACL Procedure
- DELETE_PRIVILEGE Procedure
- DROP_ACL Procedure
- UNASSIGN_ACL Procedure
- UNASSIGN_WALLET_ACL Procedure

121.3 DBMS_NETWORK_ACL_ADMIN Security Model

The EXECUTE privilege on the DBMS_NETWORK_ACL_ADMIN package is granted to the DBA role and to the EXECUTE_CATALOG_ROLE by default.

121.4 DBMS_NETWORK_ACL_ADMIN Constants

The DBMS_NETWORK_ACL_ADMIN package defines constants to use specifying parameter values.

These are shown in the following table.

Table 121-1 DBMS_NETWORK_ACL_ADMIN Constants

Constant	Type	Value	Description
IP_ADDR_MASK	VARCHAR2(80)	'([[:digit:]]+\.){3}[[:digit:]]+'	IP address mask: xxx.xxx.xxx.xxx
IP_SUBNET_MASK	VARCHAR2(80)	'([[:digit:]]+\.){0,3}*'	IP subnet mask: xxx.xxx...*
HOSTNAME_MASK	VARCHAR2(80)	'[^\.\:\/*]+(\.[^\.\:\/*]+)*'	Hostname mask: ???.???.???...???
DOMAIN_MASK	VARCHAR2(80)	'*(\.[^\.\:\/*]+)*'	Domain mask: *.???.???...???

121.5 DBMS_NETWORK_ACL_ADMIN Exceptions

The following table lists the exceptions raised by the DBMS_NETWORK_ACL_ADMIN package.

Table 121-2 DBMS_NETWORK_ACL_ADMIN Exceptions

Exception	Error Code	Description
ACE_ALREADY_EXISTS	24243	ACE already exists
EMPTY_ACL	24246	Empty ACL
ACL_NOT_FOUND	46114	ACL not found
ACL_ALREADY_EXISTS	46212	ACL already exists
INVALID_ACL_PATH	46059	Invalid ACL path

Table 121-2 (Cont.) DBMS_NETWORK_ACL_ADMIN Exceptions

Exception	Error Code	Description
INVALID_HOST	24244	Invalid host
INVALID_PRIVILEGE	24245	Invalid privilege
INVALID_WALLET_PATH	29248	Invalid wallet path
BAD_ARGUMENT	29261	Bad argument
UNRESOLVED_PRINCIPAL	46238	Unresolved principal
PRIVILEGE_NOT_GRANTED	01927	Privilege not granted

121.6 DBMS_NETWORK_ACL_ADMIN Examples

Grant the `connect` and `resolve` privileges for host `www.us.example.com` to `SCOTT`.

Example1

```
DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
  host => 'www.us.example.com',
  ace  =>  xs$ace_type(privilege_list => xs$name_list('connect', 'resolve'),
                       principal_name => 'scott',
                       principal_type => xs_acl.ptype_db));
```

Example 2

Revoke the `resolve` privilege for host `www.us.example.com` from `SCOTT`.

```
dbms_network_acl_admin.remove_host_ace(
  host => 'www.us.example.com',
  ace  =>  xs$ace_type(privilege_list => xs$name_list('resolve'),
                       principal_name => 'scott',
                       principal_type => xs_acl.ptype_db));
```

Example 3

Grant the `use_client_certificates` and `use_passwords` privileges for wallet `file:/example/wallets/hr_wallet` to `SCOTT`.

```
dbms_network_acl_admin.append_wallet_ace(
  wallet_path => 'file:/example/wallets/hr_wallet',
  ace         =>  xs$ace_type(privilege_list =>
xs$name_list('use_client_certificates', 'use_passwords'),
                              principal_name => 'scott',
                              principal_type => xs_acl.ptype_db));
```

Example 4

Revoke the `use_passwords` privilege for wallet `file:/example/wallets/hr_wallet` from `SCOTT`.

```
dbms_network_acl_admin.remove_wallet_ace(
  wallet_path => 'file:/example/wallets/hr_wallet',
  ace         =>  xs$ace_type(privilege_list => xs$name_list('use_passwords'),
                              principal_name => 'scott',
                              principal_type => xs_acl.ptype_db));
```

Example 5

The CONTAINS_HOST in the DBMS_NETWORK_ACL_UTLILITY package determines if a host is contained in a domain. It can be used in conjunction with the DBA_HOST_ACE view to determine the users and their privilege assignments to access a network host.For example, for access to www.us.example.com:

```
SELECT HOST, LOWER_PORT, UPPER_PORT,
       ACE_ORDER, PRINCIPAL, PRINCIPAL_TYPE,
       GRANT_TYPE, INVERTED_PRINCIPAL, PRIVILEGE,
       START_DATE, END_DATE
  FROM (SELECT ACES.*,
DBMS_NETWORK_ACL_UTILITY.CONTAINS_HOST('www.us.example.com',
                                                        HOST) PRECEDENCE
          FROM DBA_HOST_ACES ACES)
 WHERE PRECEDENCE IS NOT NULL
 ORDER BY PRECEDENCE DESC,
          LOWER_PORT NULLS LAST,
          UPPER_PORT NULLS LAST,
          ACE_ORDER;

HOST               LOWER_PORT UPPER_PORT ACE_ORDER PRINCIPAL PRINCIPAL_TYPE
GRANT_TYPE INVERTED_PRINCIPAL PRIVILEGE START_DATE END_DATE
------------------ ---------- ---------- --------- --------- ---------------
---------- ----------------- ---------- ---------- --------
www.us.example.com         80         80          1 SCOTT     DATABASE USER
GRANT      NO                 HTTP
www.us.example.com         80         80          2 ADAMS     DATABASE USER
GRANT      NO                 HTTP
*                                                  1 HQ_DBA    DATABASE USER
GRANT      NO                 CONNECT
*                                                  1 HQ_DBA    DATABASE USER
GRANT      NO                 RESOLVE
```

Example 6

For example, for HQ_DBA's own permission to access to www.us.example.com:

```
SELECT HOST, LOWER_PORT, UPPER_PORT, PRIVILEGE, STATUS
  FROM (SELECT ACES.*,
DBMS_NETWORK_ACL_UTILITY.CONTAINS_HOST('www.us.example.com',
                                                        HOST) PRECEDENCE
          FROM USER_HOST_ACES ACES)
 WHERE PRECEDENCE IS NOT NULL
 ORDER BY PRECEDENCE DESC,
          LOWER_PORT NULLS LAST,
          UPPER_PORT NULLS LAST;

HOST               LOWER_PORT UPPER_PORT PRIVILEGE STATUS
------------------ ---------- ---------- --------- -------
*                                        CONNECT   GRANTED
*                                        RESOLVE   GRANTED
```

121.7 Summary of DBMS_NETWORK_ACL_ADMIN Subprograms

This table lists and briefly describes the `DBMS_NETWORK_ACL_ADMIN` package subprograms.

Table 121-3 DBMS_NETWORK_ACL_ADMIN Package Subprograms

Subprogram	Description
ADD_PRIVILEGE Procedure	[DEPRECATED] Adds a privilege to grant or deny the network access to the user in an access control list (ACL)
APPEND_HOST_ACE Procedure	Appends an access control entry (ACE) to the access control list (ACL) of a network host.
APPEND_HOST_ACL Procedure	Appends access control entries (ACE) of an access control list (ACL) to the ACL of a network host
APPEND_WALLET_ACE Procedure	Appends an access control entry (ACE) to the access control list (ACL) of a wallet
APPEND_WALLET_ACL Procedure	Appends access control entries (ACE) of an access control list (ACL) to the ACL of a wallet
ASSIGN_ACL Procedure	[DEPRECATED] Assigns an access control list (ACL) to a host computer, domain, or IP subnet, and if specified, the TCP port range.
ASSIGN_WALLET_ACL Procedure	[DEPRECATED] Assigns an access control list (ACL) to a wallet
CHECK_PRIVILEGE Function	[DEPRECATED] Checks if a privilege is granted or denied the user in an access control list (ACL)
CHECK_PRIVILEGE_ACLID Function	[DEPRECATED] Checks if a privilege is granted to or denied from the user in an ACL by specifying the object ID of the access control list
CREATE_ACL Procedure	[DEPRECATED] Creates an access control list (ACL) with an initial privilege setting
DELETE_PRIVILEGE Procedure	[DEPRECATED] Deletes a privilege in an access control list (ACL)
DROP_ACL Procedure	[DEPRECATED] Drops an access control list (ACL)
REMOVE_HOST_ACE Procedure	Removes privileges from access control entries (ACE) in the access control list (ACL) of a network host matching the given ACE
REMOVE_WALLET_ACE Procedure	Removes privileges from access control entries (ACE) in the access control list (ACL) of a wallet matching the given ACE
SET_HOST_ACL Procedure	Sets the access control list (ACL) of a network host which controls access to the host from the database
SET_WALLET_ACL Procedure	Sets the access control list (ACL) of a wallet which controls access to the wallet from the database
UNASSIGN_ACL Procedure	[DEPRECATED] Unassigns the access control list (ACL) currently assigned to a network host
UNASSIGN_WALLET_ACL Procedure	[DEPRECATED] Unassigns the access control list (ACL) currently assigned to a wallet

121.7.1 ADD_PRIVILEGE Procedure

This procedure adds a privilege to grant or deny the network access to the user. The access control entry (ACE) is created if it does not exist.

> **Note:**
>
> This procedure is deprecated in Oracle Database 12*c*. While the procedure remains available in the package for reasons of backward compatibility, Oracle recommends using the APPEND_HOST_ACE Procedure and the APPEND_WALLET_ACE Procedure.

Syntax

```
DBMS_NETWORK_ACL_ADMIN.ADD_PRIVILEGE (
   acl             IN VARCHAR2,
   principal       IN VARCHAR2,
   is_grant        IN BOOLEAN,
   privilege       IN VARCHAR2,
   position        IN PLS_INTEGER DEFAULT NULL,
   start_date      IN TIMESTAMP WITH TIMESTAMP DEFAULT NULL,
   end_date        IN TIMESTAMP WITH TIMESTAMP DEFAULT NULL );
```

Parameters

Table 121-4 ADD_PRIVILEGE Function Parameters

Parameter	Description
`acl`	Name of the ACL. Relative path will be relative to "/sys/acls"
`principal`	Principal (database user or role) to whom the privilege is granted or denied. Case sensitive.
`is_grant`	Privilege is granted or denied.
`privilege`	Network privilege to be granted or denied
`position`	Position (1-based) of the ACE. If a non-`NULL` value is given, the privilege will be added in a new ACE at the given position and there should not be another ACE for the principal with the same `is_grant` (grant or deny). If a `NULL` value is given, the privilege will be added to the ACE matching the principal and the `is_grant` if one exists, or to the end of the ACL if the matching ACE does not exist.
`start_date`	Start date of the access control entry (ACE). When specified, the ACE will be valid only on and after the specified date. The `start_date` will be ignored if the privilege is added to an existing ACE.
`end_date`	End date of the access control entry (ACE). When specified, the ACE expires after the specified date. The `end_date` must be greater than or equal to the `start_date`. The `end_date` will be ignored if the privilege is added to an existing ACE.

Usage Notes

To remove the permission, use the DELETE_PRIVILEGE Procedure.

Examples

```
BEGIN
  DBMS_NETWORK_ACL_ADMIN.ADD_PRIVILEGE(
        acl         => 'us-example-com-permissions.xml',
        principal   => 'ST_USERS',
        is_grant    =>  TRUE,
        privilege   => 'connect')
END;
```

121.7.2 APPEND_HOST_ACE Procedure

This procedure appends an access control entry (ACE) to the access control list (ACL) of a network host. The ACL controls access to the given host from the database and the ACE specifies the privileges granted to or denied from the specified principal.

Syntax

```
DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE (
   host         IN VARCHAR2,
   lower_port   IN PLS_INTEGER DEFAULT NULL,
   upper_port   IN PLS_INTEGER DEFAULT NULL,
   ace          IN XS$ACE_TYPE);
```

Parameters

Table 121-5 APPEND_HOST_ACE Function Parameters

Parameter	Description
`host`	The host, which can be the name or the IP address of the host. You can use a wildcard to specify a domain or a IP subnet. The host or domain name is case-insensitive.
`lower_port`	Lower bound of an optional TCP port range
`upper_port`	Upper bound of an optional TCP port range. If `NULL`, `lower_port` is assumed.
`ace`	The ACE

Usage Notes

- Duplicate privileges in the matching ACE in the host ACL will be skipped.
- To remove the ACE, use the REMOVE_HOST_ACE Procedure.
- A host's ACL takes precedence over its domains' ACLs. For a given host, say `www.us.example.com`, the following domains are listed in decreasing precedence:
  - `www.us.example.com`
  - `*.us.example.com`
  - `*.example.com`
  - `*.com`

  - *

- An IP address' ACL takes precedence over its subnets' ACLs. For a given IP address, say `192.168.0.100`, the following subnets are listed in decreasing precedence:
  - `192.168.0.100`
  - `192.168.0.*`
  - `192.168.*`
  - `192.*`
  - *
- An ACE with a "resolve" privilege can be appended only to a host's ACL without a port range.
- When ACEs with "connect" privileges are appended to a host's ACLs with and without a port range, the one appended to the host with a port range takes precedence.
- When specifying a TCP port range of a host, it cannot overlap with other existing port ranges of the host.
- If the ACL is shared with another host or wallet, a copy of the ACL will be made before the ACL is modified.

> **See Also:**
>
> *Oracle Database Real Application Security Administrator's and Developer's Guide* for more information about the `XS$ACE_TYPE` object type

121.7.3 APPEND_HOST_ACL Procedure

This procedure appends access control entries (ACE) of an access control list (ACL) to the ACL of a network host.

Syntax

```
DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACL (
   host         IN VARCHAR2,
   lower_port   IN PLS_INTEGER DEFAULT NULL,
   upper_port   IN PLS_INTEGER DEFAULT NULL,
   acl          IN VARCHAR2);
```

Parameters

Table 121-6 APPEND_HOST_ACL Function Parameters

Parameter	Description
`host`	The host, which can be the name or the IP address of the host. You can use a wildcard to specify a domain or a IP subnet. The host or domain name is case-insensitive.
`lower_port`	Lower bound of an optional TCP port range

Table 121-6 (Cont.) APPEND_HOST_ACL Function Parameters

Parameter	Description
upper_port	Upper bound of an optional TCP port range. If NULL, lower_port is assumed.
acl	The ACL from which to append

Usage Notes

- Duplicate privileges in the matching ACE in the host ACL will be skipped.
- To remove the ACE, use the REMOVE_HOST_ACE Procedure.
- A host's ACL takes precedence over its domains' ACLs. For a given host, say www.us.example.com, the following domains are listed in decreasing precedence:
  - www.us.example.com
  - *.us.example.com
  - *.example.com
  - *.com
  - *
- An IP address' ACL takes precedence over its subnets' ACLs. For a given IP address, say 192.168.0.100, the following subnets are listed in decreasing precedence:
  - 192.168.0.100
  - 192.168.0.*
  - 192.168.*
  - 192.*
  - *
- An ACE with a "resolve" privilege can be appended only to a host's ACL without a port range.
- When ACEs with "connect" privileges are appended to a host's ACLs with and without a port range, the one appended to the host with a port range takes precedence.
- When specifying a TCP port range of a host, it cannot overlap with other existing port ranges of the host.- If the ACL is shared with another host or wallet, a copy of the ACL will be made before the ACL is modified.

121.7.4 APPEND_WALLET_ACE Procedure

This procedure appends an access control entry (ACE) to the access control list (ACL) of a wallet. The ACL controls access to the given wallet from the database and the ACE specifies the privileges granted to or denied from the specified principal.

Syntax

```
DBMS_NETWORK_ACL_ADMIN.APPEND_WALLET_ACE (
   wallet_path    IN VARCHAR2,
   ace            IN XS$ACE_TYPE);
```

Parameters

Table 121-7 APPEND_WALLET_ACE Function Parameters

Parameter	Description
`wallet_path`	Directory path of the wallet. The path is case-sensitive of the format `file:`*`directory-path`*.
`ace`	The ACE

Usage Notes

- Duplicate privileges in the matching ACE in the host ACL will be skipped.
- To remove the ACE, use the REMOVE_WALLET_ACE Procedure.
- If the ACL is shared with another host or wallet, a copy of the ACL is made before the ACL is modified.

> **See Also:**
>
> *Oracle Database Real Application Security Administrator's and Developer's Guide* for more information about the `XS$ACE_TYPE` object type

121.7.5 APPEND_WALLET_ACL Procedure

This procedure appends access control entries (ACE) of an access control list (ACL) to the ACL of a wallet.

Syntax

```
DBMS_NETWORK_ACL_ADMIN.APPEND_WALLET_ACL (
   wallet_path    IN VARCHAR2,
   acl            IN VARCHAR2);
```

Parameters

Table 121-8 APPEND_WALLET_ACL Function Parameters

Parameter	Description
`wallet_path`	Directory path of the wallet. The path is case-sensitive of the format `file:`*`directory-path`*.
`ace`	The ACL from which to append

Usage Notes

- Duplicate privileges in the matching ACE in the host ACL will be skipped.
- To remove the ACE, use REMOVE_WALLET_ACE.
- If the ACL is shared with another host or wallet, a copy of the ACL is made before the ACL is modified.

121.7.6 ASSIGN_ACL Procedure

This procedure assigns an access control list (ACL) to a host computer, domain, or IP subnet, and if specified, the TCP port range.

> **Note:**
>
> This procedure is deprecated in Oracle Database 12*c*. While the procedure remains available in the package for reasons of backward compatibility, Oracle recommends using the APPEND_HOST_ACE Procedure and the APPEND_WALLET_ACE Procedure.

Syntax

```
DBMS_NETWORK_ACL_ADMIN.ASSIGN_ACL (
   acl         IN VARCHAR2,
   host        IN VARCHAR2,
   lower_port  IN PLS_INTEGER DEFAULT NULL,
   upper_port  IN PLS_INTEGER DEFAULT NULL);
```

Parameters

Table 121-9 ASSIGN_ACL Function Parameters

Parameter	Description
`acl`	Name of the ACL. Relative path will be relative to "`/sys/acls`".
`host`	Host to which the ACL is to be assigned. The host can be the name or the IP address of the host. A wildcard can be used to specify a domain or a IP subnet. The host or domain name is case-insensitive.
`lower_port`	Lower bound of a TCP port range if not `NULL`
`upper_port`	Upper bound of a TCP port range. If `NULL`, `lower_port` is assumed.

Usage Notes

- Only one ACL can be assigned to any host computer, domain, or IP subnet, and if specified, the TCP port range. When you assign a new access control list to a network target, Oracle Database unassigns the previous access control list that was assigned to the same target. However, Oracle Database does not drop the access control list. You can drop the access control list by using the DROP_ACL Procedure. To remove an access control list assignment, use the UNASSIGN_ACL Procedure.
- The ACL assigned to a domain takes a lower precedence than the other ACLs assigned sub-domains, which take a lower precedence than the ACLs assigned to the individual hosts. So for a given host, for example, "www.us.example.com", the following domains are listed in decreasing precedences:

  - www.us.example.com

  - *.us.example.com

  - *.example.com

- *.com

- *

In the same way, the ACL assigned to an subnet takes a lower precedence than the other ACLs assigned smaller subnets, which take a lower precedence than the ACLs assigned to the individual IP addresses. So for a given IP address, for example, "192.168.0.100", the following subnets are listed in decreasing precedences:

- 192.168.0.100

- 192.168.0.*

- 192.168.*

- 192.*

- *

- The port range is applicable only to the "connect" privilege assignments in the ACL. The "resolve" privilege assignments in an ACL have effects only when the ACL is assigned to a host without a port range.

  For the "connect" privilege assignments, an ACL assigned to the host without a port range takes a lower precedence than other ACLs assigned to the same host with a port range.

- When specifying a TCP port range, both `lower_port` and `upper_port` must not be `NULL` and `upper_port` must be greater than or equal to `lower_port`. The port range must not overlap with any other port ranges for the same host assigned already.

- To remove the assignment, use UNASSIGN_ACL Procedure.

Examples

```
BEGIN
   DBMS_NETWORK_ACL_ADMIN.ASSIGN_ACL(
     acl         => 'us-example-com-permissions.xml',
     host        => '*.us.example.com',
     lower_port  => 80);
END;
```

121.7.7 ASSIGN_WALLET_ACL Procedure

This procedure assigns an access control list (ACL) to a wallet.

> **Note:**
>
> This procedure is deprecated in Oracle Database 12*c*. While the procedure remains available in the package for reasons of backward compatibility, Oracle recommends using the APPEND_HOST_ACE Procedure and the APPEND_WALLET_ACE Procedure.

Syntax

```
UTL_HTTP.ASSIGN_WALLET_ACL (
   acl          IN  VARCHAR2,
   wallet_path  IN  VARCHAR2);
```

Parameters

Table 121-10 ASSIGN_WALLET_ACL Procedure Parameters

Parameter	Description
`acl`	Name of the ACL. Relative path will be relative to "`/sys/acls`"
`wallet_path`	Directory path of the wallet to which the ACL is to be assigned. The path is case-sensitive and of the format `file:`*`directory-path`*.

Usage Notes

To remove the assignment, use the UNASSIGN_WALLET_ACL Procedure.

Examples

```
BEGIN
  DBMS_NETWORK_ACL_ADMIN.CREATE_ACL(
    acl         => 'wallet-acl.xml',
    description => 'Wallet ACL',
    principal   => 'SCOTT',
    is_grant    => TRUE,
    privilege   => 'use-client-certificates');

  DBMS_NETWORK_ACL_ADMIN.ADD_PRIVILEGE(
    acl         => 'wallet-acl.xml',
    principal   => 'SCOTT',
    is_grant    => TRUE,
    privilege   => 'use-passwords');

  DBMS_NETWORK_ACL_ADMIN.ASSIGN_WALLET_ACL(
    acl         => 'wallet-acl.xml',
    wallet_path => 'file:/example/wallets/test_wallet');
END;
```

121.7.8 CHECK_PRIVILEGE Function

This function checks if a privilege is granted or denied the user in an ACL.

> **Note:**
>
> This procedure is deprecated in Oracle Database 12*c*. The procedure remains available in the package only for reasons of backward compatibility.

Syntax

```
DBMS_NETWORK_ACL_ADMIN.CHECK_PRIVILEGE (
   acl             IN VARCHAR2,
   user            IN VARCHAR2,
   privilege       IN VARCHAR2)
  RETURN NUMBER;
```

Parameters

Table 121-11 CHECK_PRIVILEGE Function Parameters

Parameter	Description
acl	Name of the ACL. Relative path will be relative to "/sys/acls".
user	User to check against. If the user is NULL, the invoker is assumed. The username is case-sensitive as in the USERNAME column of the ALL_USERS view.
privilege	Network privilege to check

Return Values

Returns 1 when the privilege is granted; 0 when the privilege is denied; NULL when the privilege is neither granted or denied.

Examples

```
SELECT DECODE(
  DBMS_NETWORK_ACL_ADMIN.CHECK_PRIVILEGE(
       'us-example-com-permissions.xml', 'SCOTT', 'resolve'),
  1, 'GRANTED', 0, 'DENIED', NULL) PRIVILEGE
FROM DUAL;
```

121.7.9 CHECK_PRIVILEGE_ACLID Function

This function checks if a privilege is granted to or denied from the user in an ACL by specifying the object ID of the access control list.

> **Note:**
>
> This procedure is deprecated in Oracle Database 12*c*. The procedure remains available in the package only for reasons of backward compatibility.

Syntax

```
DBMS_NETWORK_ACL_ADMIN.CHECK_PRIVILEGE_ACLID (
   aclid           IN RAW,
   user            IN VARCHAR2 DEFAULT NULL)
   privilege       IN VARCHAR2,
 RETURN NUMBER;
```

Parameters

Table 121-12 CHECK_PRIVILEGE_ACLID Function Parameters

Parameter	Description
aclid	Object ID of the ACL

Table 121-12 (Cont.) CHECK_PRIVILEGE_ACLID Function Parameters

Parameter	Description
`user`	User to check against. If the user is `NULL`, the invoker is assumed. The username is case-sensitive as in the `USERNAME` column of the `ALL_USERS` view.
`privilege`	Network privilege to check

Return Values

Returns 1 when the privilege is granted; 0 when the privilege is denied; `NULL` when the privilege is neither granted or denied.

121.7.10 CREATE_ACL Procedure

This deprecated procedure creates an access control list (ACL) with an initial privilege setting. An ACL must have at least one privilege setting. The ACL has no access control effect unless it is assigned to the network target.

> **Note:**
>
> This procedure is deprecated in Oracle Database 12*c*. While the procedure remains available in the package for reasons of backward compatibility, Oracle recommends using the APPEND_HOST_ACE Procedure and the APPEND_WALLET_ACE Procedure.

Syntax

```
DBMS_NETWORK_ACL_ADMIN.CREATE_ACL (
   acl             IN VARCHAR2,
   description     IN VARCHAR2,
   principal       IN VARCHAR2,
   is_grant        IN BOOLEAN,
   privilege       IN VARCHAR2,
   start_date      IN TIMESTAMP WITH TIMEZONE DEFAULT NULL,
   end_date        IN TIMESTAMP WITH TIMEZONE DEFAULT NULL );
```

Parameters

Table 121-13 CREATE_ACL Procedure Parameters

Parameter	Description
`acl`	Name of the ACL. Relative path will be relative to "/sys/acls".
`description`	Description attribute in the ACL
`principal`	Principal (database user or role) to whom the privilege is granted or denied. Case sensitive.
`is_grant`	Privilege is granted or not (denied)

Table 121-13 (Cont.) CREATE_ACL Procedure Parameters

Parameter	Description
privilege	Network privilege to be granted or denied - 'connect | resolve' (case sensitive). A database user needs the connect privilege to an external network host computer if he or she is connecting using the UTL_TCP, UTL_HTTP, UTL_SMTP, and UTL_MAIL utility packages. To resolve a host name that was given a host IP address, or the IP address that was given a host name, with the UTL_INADDR package, grant the database user the resolve privilege.
start_date	Start date of the access control entry (ACE). When specified, the ACE is valid only on and after the specified date.
end_date	End date of the access control entry (ACE). When specified, the ACE expires after the specified date. The end_date must be greater than or equal to the start_date.

Usage Notes

To drop the access control list, use the DROP_ACL Procedure.

Examples

```
BEGIN
  DBMS_NETWORK_ACL_ADMIN.CREATE_ACL(
     acl          => 'us-example-com-permissions.xml',
     description  => 'Network permissions for *.us.example.com',
     principal    => 'SCOTT',
     is_grant     => TRUE,
     privilege    => 'connect');
END;
```

121.7.11 DELETE_PRIVILEGE Procedure

This deprecated procedure deletes a privilege in an access control list.

> **Note:**
>
> This procedure is deprecated in Oracle Database 12*c*. While the procedure remains available in the package for reasons of backward compatibility, Oracle recommends using the REMOVE_HOST_ACE Procedure and the REMOVE_WALLET_ACE Procedure.

Syntax

```
DBMS_NETWORK_ACL_ADMIN.DELETE_PRIVILEGE (
   acl           IN VARCHAR2,
   principal     IN VARCHAR2,
   is_grant      IN BOOLEAN DEFAULT NULL,
   privilege     IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 121-14 DELETE_PRIVILEGE Function Parameters

Parameter	Description
`acl`	Name of the ACL. Relative path will be relative to "/sys/acls".
`principal`	Principal (database user or role) for whom all the ACE will be deleted
`is_grant`	Privilege is granted or not (denied). If a `NULL` value is given, the deletion is applicable to both granted or denied privileges.
`privilege`	Network privilege to be deleted. If a `NULL` value is given, the deletion is applicable to all privileges.

Examples

```
BEGIN
  DBMS_NETWORK_ACL_ADMIN.DELETE_PRIVILEGE(
        acl         => 'us-example-com-permissions.xml',
        principal   => 'ST_USERS')
END;
```

121.7.12 DROP_ACL Procedure

This **deprecated procedure** drops an access control list (ACL).

> **Note:**
>
> This procedure is deprecated in Oracle Database 12*c*. The procedure remains available in the package only for reasons of backward compatibility.

Syntax

```
DBMS_NETWORK_ACL_ADMIN.DROP_ACL (
   acl           IN VARCHAR2);
```

Parameters

Table 121-15 DROP_ACL Procedure Parameters

Parameter	Description
`acl`	Name of the ACL. Relative path will be relative to "/sys/acls".

Examples

```
BEGIN
   DBMS_NETWORK_ACL_ADMIN.DROP_ACL(
      acl => 'us-example-com-permissions.xml');
END;
```

121.7.13 REMOVE_HOST_ACE Procedure

This procedure removes privileges from access control entries (ACE) in the access control list (ACL) of a network host matching the given ACE.

Syntax

```
DBMS_NETWORK_ACL_ADMIN.REMOVE_HOST_ACE (
   host               IN VARCHAR2,
   lower_port         IN PLS_INTEGER DEFAULT NULL,
   upper_port         IN PLS_INTEGER DEFAULT NULL,
   ace                IN XS$ACE_TYPE,
   remove_empty_acl   IN BOOLEAN DEFAULT FALSE);
```

Parameters

Table 121-16 REMOVE_HOST_ACE Function Parameters

Parameter	Description
`host`	The host, which can be the name or the IP address of the host. You can use a wildcard to specify a domain or a IP subnet. The host or domain name is case-insensitive.
`lower_port`	Lower bound of an optional TCP port range
`upper_port`	Upper bound of an optional TCP port range. If `NULL`, `lower_port` is assumed.
`ace`	The ACE
`remove_empty_acl`	Whether to remove the ACL when it becomes empty when the ACE is removed

Usage Notes

If the ACL is shared with another host or wallet, a copy of the ACL is made before the ACL is modified.

121.7.14 REMOVE_WALLET_ACE Procedure

This procedure removes privileges from access control entries (ACE) in the access control list (ACL) of a wallet matching the given ACE.

Syntax

```
DBMS_NETWORK_ACL_ADMIN.REMOVE_WALLET_ACE (
   wallet_path        IN VARCHAR2,
   ace                IN XS$ACE_TYPE,
   remove_empty_acl   IN BOOLEAN DEFAULT FALSE);
```

Parameters

Table 121-17 REMOVE_WALLET_ACE Function Parameters

Parameter	Description
`wallet_path`	Directory path of the wallet. The path is case-sensitive of the format `file:`*`directory-path`*.
`ace`	The ACE
`remove_empty_acl`	Whether to remove the ACL when it becomes empty when the ACE is removed

Usage Notes

If the ACL is shared with another host or wallet, a copy of the ACL is made before the ACL is modified.

121.7.15 SET_HOST_ACL Procedure

This procedure sets the access control list (ACL) of a network host which controls access to the host from the database.

Syntax

```
DBMS_NETWORK_ACL_ADMIN.SET_HOST_ACL (
   host         IN VARCHAR2,
   lower_port   IN PLS_INTEGER DEFAULT NULL,
   upper_port   IN PLS_INTEGER DEFAULT NULL,
   acl          IN VARCHAR2);
```

Parameters

Table 121-18 SET_HOST_ACL Function Parameters

Parameter	Description
`host`	The host, which can be the name or the IP address of the host. You can use a wildcard to specify a domain or a IP subnet. The host or domain name is case-insensitive.
`lower_port`	Lower bound of an optional TCP port range
`upper_port`	Upper bound of an optional TCP port range. If `NULL`, `lower_port` is assumed.
`acl`	The ACL. `NULL` to unset the host's ACL.

Usage Notes

A host's ACL is created and set on-demand when an access control entry (ACE) is appended to the host's ACL. Users are discouraged from setting a host's ACL manually.

121.7.16 SET_WALLET_ACL Procedure

This procedure sets the access control list (ACL) of a wallet which controls access to the wallet from the database.

Syntax

```
DBMS_NETWORK_ACL_ADMIN.SET_WALLET_ACL (
   wallet_path    IN VARCHAR2,
   acl            IN VARCHAR2);
```

Parameters

Table 121-19 SET_WALLET_ACL Function Parameters

Parameter	Description
`wallet_path`	Directory path of the wallet. The path is case-sensitive of the format `file:`*`directory-path`*.
`acl`	The ACL. `NULL` to unset the host's ACL.

Usage Notes

A wallet's ACL is created and set on-demand when an access control entry (ACE) is appended to the wallet's ACL. Users are discouraged from setting a wallet's ACL manually.

121.7.17 UNASSIGN_ACL Procedure

This deprecated procedure unassigns the access control list (ACL) currently assigned to a network host.

> **Note:**
>
> This procedure is deprecated in Oracle Database 12*c*. While the procedure remains available in the package for reasons of backward compatibility, Oracle recommends using the REMOVE_HOST_ACE Procedure and the REMOVE_WALLET_ACE Procedure.

Syntax

```
DBMS_NETWORK_ACL_ADMIN.UNASSIGN_ACL (
   acl         IN VARCHAR2 DEFAULT NULL,
   host        IN VARCHAR2 DEFAULT NULL,
   lower_port  IN PLS_INTEGER DEFAULT NULL,
   upper_port  IN PLS_INTEGER DEFAULT NULL);
```

Parameters

Table 121-20 UNASSIGN_ACL Function Parameters

Parameter	Description
acl	Name of the ACL. Relative path will be relative to "/sys/acls". If ACL is NULL, any ACL assigned to the host is unassigned.
host	Host from which the ACL is to be removed. The host can be the name or the IP address of the host. A wildcard can be used to specify a domain or a IP subnet. The host or domain name is case-insensitive. If host is NULL, the ACL will be unassigned from any host. If both host and acl are NULL, all ACLs assigned to any hosts are unassigned.
lower_port	Lower bound of a TCP port range if not NULL
upper_port	Upper bound of a TCP port range. If NULL, lower_port is assumed.

Examples

```
BEGIN
   DBMS_NETWORK_ACL_ADMIN.UNASSIGN_ACL(
     host        => '*.us.example.com',
     lower_port  => 80);
END;
```

121.7.18 UNASSIGN_WALLET_ACL Procedure

This deprecated procedure unassigns the access control list (ACL) currently assigned to a wallet.

> **Note:**
>
> This procedure is deprecated in Oracle Database 12*c*. While the procedure remains available in the package for reasons of backward compatibility, Oracle recommends using the REMOVE_HOST_ACE Procedure and the REMOVE_WALLET_ACE Procedure.

Syntax

```
UTL_HTTP.UNASSIGN_WALLET_ACL (
   acl          IN  VARCHAR2 DEFAULT NULL,
   wallet_path  IN  VARCHAR2 DEFAULT NULL);
```

Parameters

Table 121-21 UNASSIGN_WALLET_ACL Procedure Parameters

Parameter	Description
acl	Name of the ACL. Relative path will be relative to "/sys/acls". If acl is NULL, any ACL assigned to the wallet is unassigned

Table 121-21 (Cont.) UNASSIGN_WALLET_ACL Procedure Parameters

Parameter	Description
`wallet_path`	Directory path of the wallet to which the ACL is assigned. The path is case-sensitive and of the format `file:`*`directory-path`*. If both `acl` and `wallet_path` are `NULL`, all ACLs assigned to any wallets are unassigned.

Examples

```
BEGIN
  DBMS_NETWORK_ACL_ADMIN.UNASSIGN_WALLET_ACL(
    acl         => 'wallet-acl.xml',
    wallet_path => 'file:/example/wallets/test_wallet');
END;
```

122
DBMS_NETWORK_ACL_UTILITY

The DBMS_NETWORK_ACL_UTILITY package provides the utility functions to facilitate the evaluation of access control list (ACL) assignments governing TCP connections to network hosts.

> **See Also:**
>
> For more information, see ""Managing Fine-grained Access to External Network Services"" in *Oracle Database Security Guide*

The chapter contains the following topics:

- Security Model
- Examples
- Summary of DBMS_NETWORK_ACL_UTILITY Subprograms

122.1 DBMS_NETWORK_ACL_UTILITY Security Model

EXECUTE on the DBMS_NETWORK_ACL_UTILITY package is granted to PUBLIC.

122.2 DBMS_NETWORK_ACL_UTILITY Examples

The CONTAINS_HOST Function in this package indicates if a domain or subnet contains a given host or IP address.

It can be used in conjunction with the CHECK_PRIVILEGE_ACLID Function in the DBMS_NETWORK_ACL_ADMIN package to determine the privilege assignments affecting a user's permission to access a network host. The return value of the CONTAINS_HOST Function in can also be used to order the ACL assignments by their precedence.

Example 1

For example, for SCOTT's permission to connect to www.hr.example.com:

```
SELECT host, lower_port, upper_port, acl,
   DECODE(
       DBMS_NETWORK_ACL_ADMIN.CHECK_PRIVILEGE_ACLID(aclid, 'SCOTT', 'connect'),
          1, 'GRANTED', 0, 'DENIED', NULL) privilege
   FROM (SELECT host, acl, aclid, lower_port, upper_port,
             DBMS_NETWORK_ACL_UTILITY.CONTAINS_HOST('www.hr.example.com', host)
               precedence
         FROM dba_network_acls)
WHERE precedence > 0
ORDER BY precedence DESC, lower_port nulls LAST;
```

```
HOST                 LOWER_PORT UPPER_PORT  ACL                  PRIVILEGE
-------------------- ---------- ---------- -------------------- ---------
www.hr.example.com           80         80  /sys/acls/www.xml    GRANTED
www.hr.example.com         3000       3999  /sys/acls/www.xml    GRANTED
www.hr.example.com                         /sys/acls/www.xml    GRANTED
*.hr.example.com                           /sys/acls/all.xml
*.example.com                              /sys/acls/all.xml
```

Example 2

For example, for SCOTT's permission to do domain name resolution for www.hr.example.com:

```
SELECT host, acl,
  DECODE(
    DBMS_NETWORK_ACL_ADMIN.CHECK_PRIVILEGE_ACLID(aclid, 'SCOTT', 'resolve'),
      1, 'GRANTED', 0, 'DENIED', null) privilege
  FROM (SELECT host, acl, aclid,
               DBMS_NETWORK_ACL_UTILITY.CONTAINS_HOST('www.hr.example.com', host)
                 precedence
          FROM dba_network_acls
         WHERE lower_port IS NULL AND upper_port IS NULL)
 WHERE precedence > 0
 ORDER BY precedence DESC;

HOST                 ACL                          PRIVILEGE
-------------------- ---------------------------- ---------
www.hr.example.com   /sys/acls/hr-www.xml         GRANTED
*.hr.example.com     /sys/acls/hr-domain.xml
*.example.com        /sys/acls/corp-domain.xml
```

Note that the "resolve" privilege takes effect only in ACLs assigned without any port range (when `lower_port` and `upper_port` are `NULL`). For this reason, the example does not include `lower_port` and `upper_port` columns in the query.

Related Topics

- CONTAINS_HOST Function
  This function determines if the given host is equal to or contained in the given host, domain, or subnet. It handles different representation of the same IP address or subnet. For example, an IPv4-mapped IPv6 address is considered equal to the IPv4-native address it represents. It does not perform domain name resolution when evaluating the host or domain.

122.3 Summary of DBMS_NETWORK_ACL_UTILITY Subprograms

This table lists and briefly describes the `DBMS_NETWORK_ACL_UTILITY` package subprograms.

Table 122-1 DBMS_NETWORK_ACL_UTILITY Package Subprograms

Subprogram	Description
CONTAINS_HOST Function	Determines if the given host is equal to or contained in the given host, domain, or subnet

Table 122-1 (Cont.) DBMS_NETWORK_ACL_UTILITY Package Subprograms

Subprogram	Description
DOMAIN_LEVEL Function	Returns the domain level of the given host name, domain, or subnet
DOMAINS Function	For a given host, this function returns the domains whose ACL assigned is used to determine if a user has the privilege to access the given host or not.
EQUALS_HOST Function	Determines if the two given hosts, domains, or subnets are equal

122.3.1 CONTAINS_HOST Function

This function determines if the given host is equal to or contained in the given host, domain, or subnet. It handles different representation of the same IP address or subnet. For example, an IPv4-mapped IPv6 address is considered equal to the IPv4-native address it represents. It does not perform domain name resolution when evaluating the host or domain.

Syntax

```
DBMS_NETWORK_ACL_UTILITY.CONTAINS_HOST (
   host      IN    VARCHAR2,
   domain    IN    VARCHAR2)
 RETURN NUMBER;
```

Parameters

Table 122-2 CONTAINS_HOST Function Parameters

Parameter	Description
`host`	Network host
`domain`	Network host, domain, or subnet

Return Values

Returns a non-`NULL` value if the given host is equal to or contained in the related host, domain, or subnet:

- If `domain` is a hostname, returns the level of its domain + 1
- If `domain` is a domain name, returns the domain level
- If `domain` is an IP address or subnet, return the number of significant address bits of the IP address or subnet
- If domain is the wildcard "*", returns 0

The non-`NULL` value returned indicates the precedence of the domain or subnet for ACL assignment. The higher the value, the higher is the precedence. `NULL` will be returned if the host is not equal to or contained in the given host, domain or subnet.

Examples

```
SELECT host, acl, precedence
  FROM (select host, acl,
               DBMS_NETWORK_ACL_UTILITY.CONTAINS_HOST('192.0.2.3', host)
                 precedence
          FROM dba_network_acls)
 WHERE precedence > 0
 ORDER BY precedence DESC;

HOST                 ACL                        PRECEDENCE
-------------------- -------------------------- ----------
192.0.2.3            /sys/acls/hr-www.xml               32
::ffff:192.0.2.0/120 /sys/acls/hr-domain.xml            24
::ffff:192.0.0.0/104 /sys/acls/corp-domain.xml           8
```

122.3.2 DOMAIN_LEVEL Function

This function returns the domain level of the given host name, domain, or subnet.

Syntax

```
DBMS_NETWORK_ACL_UTILITY.DOMAIN_LEVEL (
    host  IN VARCHAR2)
  RETURN NUMBER;
```

Parameters

Table 122-3 DOMAIN_LEVEL Function Parameters

Parameter	Description
host	Network host, domain, or subnet

Return Values

The domain level of the given host, domain, or subnet.

Usage Notes

Note that this function cannot handle IPv6 addresses and subnets, and subnets in CIDR notation.

Examples

```
SELECT host, acl, domain_level
  FROM (select host, acl,
               DBMS_NETWORK_ACL_UTILITY.DOMAIN_LEVEL(host) domain_level
          FROM dba_network_acls)
 order by domain_level desc;

HOST                 ACL                          DOMAIN_LEVEL
-------------------- ---------------------------- ------------
www.hr.example.com   /sys/acls/hr-www.xml                    4
*.hr.example.com     /sys/acls/hr-domain.xml                 3
*.example.com        /sys/acls/corp-domain.xml               2
```

122.3.3 DOMAINS Function

For a given host, this function returns the domains whose ACL assigned determines if a user has the privilege to access the given host or not. When the IP address of the host is given, return the subnets instead.

Syntax

```
DBMS_NETWORK_ACL_UTILITY.DOMAINS (
    host  IN VARCHAR2)
  RETURN DOMAIN_TABLE PIPELINED;
```

Parameters

Table 122-4 DOMAINS Function Parameters

Parameter	Description
host	Network host

Return Values

The domains or subnets for the given host.

Usage Notes

Note that this function cannot handle IPv6 addresses. Nor can it generate subnets of arbitrary number of prefix bits for an IPv4 address.

Examples

```
select * from table(dbms_network_acl_utility.domains('www.hr.example.com'));

DOMAINS
-------------------------
www.hr.example.com
*.hr.example.com
*.example.com
*.com
*
```

122.3.4 EQUALS_HOST Function

This function determines if the two given hosts, domains, or subnets are equal. It handles different representation of the same IP address or subnet. For example, an IPv4-mapped IPv6 address is considered equal to the IPv4- native address it represents. It does not perform domain name resolution when comparing the two hosts or domains.

Syntax

```
DBMS_NETWORK_ACL_UTILITY.EQUALS_HOST (
   host1    IN    VARCHAR2,
   host2    IN    VARCHAR2)
 RETURN NUMBER;
```

Parameters

Table 122-5 EQUALS_HOST Function Parameters

Parameter	Description
host1	Network host, domain, or subnet to compare
host2	Network host, domain, or subnet to compare

Return Values

1 if the two hosts, domains, or subnets are equal. 0 otherwise.

Examples

```
SELECT host, acl
  FROM dba_network_acls
 WHERE DBMS_NETWORK_ACL_UTILITY.EQUALS_HOST('192.0.2.*', host) = 1;

HOST                 ACL
-------------------- ----------------------------
::ffff:192.0.2.0/120   /sys/acls/hr-domain.xml
```

123
DBMS_ODCI

DBMS_ODCI package contains a single user function related to the use of Data Cartridges.

This chapter contains the following topic:

- Summary of DBMS_ODCI Subprograms

> **See Also:**
>
> - *Oracle Database Data Cartridge Developer's Guide*

123.1 Summary of DBMS_ODCI Subprograms

The DBMS_ODCI package has one subprogram, the ESTIMATE_CPU_UNITS function.

Table 123-1 ***DBMS_ODCI Package Subprograms***

Subprogram	Description
ESTIMATE_CPU_UNITS Function	Returns the approximate number of CPU instructions (in thousands) corresponding to a specified time interval (in seconds)

123.1.1 ESTIMATE_CPU_UNITS Function

This function returns the approximate number of CPU instructions (in thousands) corresponding to a specified time interval (in seconds). This information can be used to associate the CPU cost with a user-defined function for the extensible optimizer.

The function takes as input the elapsed time of the user function, measures CPU units by multiplying the elapsed time by the processor speed of the machine, and returns the approximate number of CPU instructions that should be associated with the user function. For a multiprocessor machine, ESTIMATE_CPU_UNITS considers the speed of a single processor.

Syntax

```
DBMS_ODCI.ESTIMATE_CPU_UNITS(
   elapsed_time     NUMBER)
  RETURN NUMBER;
```

Parameters

Parameter	Description
elapsed_time	The elapsed time in seconds that it takes to execute a function.

Usage Notes

When associating CPU cost with a user-defined function, use the full number of CPU units rather than the number of *thousands* of CPU units returned by `ESTIMATE_CPU_UNITS`; multiply the number returned by `ESTIMATE_CPU_UNITS` by 1,000.

124
DBMS_OPTIM_BUNDLE

The DBMS_OPTIM_BUNDLE package is used to manage the installed but disabled module bug fixes which cause an execution plan change.

This chapter contains the following topics:

- DBMS_OPTIM_BUNDLE Security Model
- Summary of DBMS_OPTIM_BUNDLE Subprograms

124.1 DBMS_OPTIM_BUNDLE Security Model

The DBMS_OPTIM_BUNDLE package runs with the privileges of the user starting the package. DBA role is required to run this package.

124.2 Summary of DBMS_OPTIM_BUNDLE Subprograms

This table lists the DBMS_OPTIM_BUNDLE subprograms and briefly describes them.

Table 124-1 DBMS_OPTIM_BUNDLE Package Subprograms

Subprogram	Description
ENABLE_OPTIM_FIXES Procedure	This procedure enables or disables fixes with plan changes up to the latest installed release update.
GETBUGSFORBUNDLE Procedure	This procedure displays execution plan bug fixes applied as part of release updates.
LISTBUNDLESWITHFCFIXES Procedure	This procedure lists the release update names and release update IDs of release updates with fix control fixes.
SET_FIX_CONTROLS Procedure	This procedure enables or disables a list of fixes with _fix_controls.

124.2.1 ENABLE_OPTIM_FIXES Procedure

The DBMS_OPTIM_BUNDLE subprogram, ENABLE_OPTIM_FIXES procedure enables or disables fixes with plan changes up to the latest installed release update.

Syntax

```
DBMS_OPTIM_BUNDLE.ENABLE_OPTIM_FIXES (
   action                          IN  VARCHAR2  DEFAULT 'OFF',
   scope                           IN  VARCHAR2  DEFAULT 'MEMORY',
   current_setting_precedence      IN  VARCHAR2  DEFAULT 'YES');
```

Parameters

Table 124-2 ENABLE_OPTIM_FIXES Procedure Parameters

Parameter	Description
action	Enables or disables all of the installed but disabled execution plan bug fixes up to and including the current release update. The possible values are: • ON-enables the bundle fixes. • OFF-disables bundle fixes by setting the _fix_controls to the value 0. It will not remove _fix_control entries from SPFILE. The default value is OFF.
scope	The scope of enabling or disabling the installed but disabled execution plan bug fixes. The possible values are: • MEMORY • SPFILE • BOTH • INITORA MEMORY/SPFILE/BOTH: These three input values enables or disables the fixes in a given scope. INITORA: This input value will just display manual command syntax that the user needs to manually enter into the database's init.ora file in order to enable or disable execution plan bug fixes. When using SCOPE=INITORA in this way, the current_setting_precedence field has no significance.
current_setting_precedence	Sets the precedence of environment settings or release update settings, where these settings are in conflict. The possible values are: • YES-the current environment settings take precedence in case of conflict • NO-release update settings take precedence in case of conflict The default value is YES.

Examples

To enable all of the installed but disabled execution plan bug fixes up to and including those from the current release update:

```
SQL> execute dbms_optim_bundle.enable_optim_fixes('ON','BOTH', 'YES');
```

This instruction would enable all fixes, in both MEMORY and in the persistant SPFILE, with a precedence of current setting.

Exceptions

The following exceptions are raised by the ENABLE_OPTIM_FIXES Procedure:

- ORA-20001: Bad input value
- ORA-20002: Internal or other errors

124.2.2 GETBUGSFORBUNDLE Procedure

The DBMS_OPTIM_BUNDLE subprogram, GETBUGSFORBUNDLE procedure displays execution plan bug fixes applied as part of release updates.

Syntax

```
DBMS_OPTIM_BUNDLE.GETBUGSFORBUNDLE (
   bundleid            IN  NUMBER  DEFAULT NULL);
```

Parameters

Table 124-3 GETBUGSFORBUNDLE Procedure Parameters

Parameter	Description
bundleid	The release update ID. If NULL, the execution plan bug fixes from the latest bundle is displayed. If a bundle ID is specified, then the execution plan bug fixes up to the specified bundle is displayed. The default value is NULL.

Examples

To view a listing of the installed but disabled execution plan bug fixes from the most recent release update applied:

```
SQL> set serveroutput on;
SQL> execute dbms_optim_bundle.getbugsforbundle;

19.8.0.0.200714DBRU:
   Bug: 29304314, fix_controls: 29304314
   Bug: 29930457, fix_controls: 29930457
```

The above example lists the installed but disabled execution plan bug fixes from the 19.8.0.0.200714DBRU release.

To view a listing of the installed but disabled execution plan bug fixes from release updates up to and including release update 171017:

```
SQL> execute dbms_optim_bundle.getbugsforbundle(171017);
```

Exceptions

The following exceptions are raised by the GETBUGSFORBUNDLE Procedure:

- ORA-20001: Bad input value
- ORA-20002: Internal or other errors

124.2.3 LISTBUNDLESWITHFCFIXES Procedure

The DBMS_OPTIM_BUNDLE subprogram, LISTBUNDLESWITHFCFIXES procedure lists the release update names and release update IDs of release updates with fix control fixes.

Syntax

```
DBMS_OPTIM_BUNDLE.LISTBUNDLESWITHFCFIXES ( );
```

Examples

To view the release update names and release update IDs:

```
SQL> set serveroutput on
SQL> exec dbms_optim_bundle.listBundlesWithFCFixes;
   bundleId: 190719, bundleName: 19.4.0.0.190719DBRU
   bundleId: 191015, bundleName: 19.5.0.0.191015DBRU
   bundleId: 200414, bundleName: 19.7.0.0.200414DBRU
   bundleId: 200714, bundleName: 19.8.0.0.200714DBRU
   bundleId: 201020, bundleName: 19.9.0.0.201020DBRU
   bundleId: 210119, bundleName: 19.10.0.0.210119DBRU
   bundleId: 210420, bundleName: 19.11.0.0.210420DBRU
   bundleId: 210720, bundleName: 19.12.0.0.210720DBRU

   PL/SQL procedure successfully completed.
```

Exceptions

The following exception is raised by the LISTBUNDLESWITHFCFIXES Procedure:

ORA-20002: Internal or other errors

124.2.4 SET_FIX_CONTROLS Procedure

The DBMS_OPTIM_BUNDLE subprogram, SET_FIX_CONTROLS procedure enables or disables a list of fixes with _fix_controls. The fixes can be present in a base version, in a release update, or in a one-off release. This procedure appends the new fix control settings to the existing ones.

Syntax

```
DBMS_OPTIM_BUNDLE.SET_FIX_CONTROLS (
   fix_control_string               IN  VARCHAR2,
   sid                              IN  VARCHAR2  DEFAULT '*',
   scope                            IN  VARCHAR2  DEFAULT 'MEMORY',
   current_setting_precedence       IN  VARCHAR2  DEFAULT 'YES');
```

Parameters

Table 124-4 SET_FIX_CONTROLS Procedure Parameters

Parameter	Description
fix_control_string	Comma separated list of fix_control:value pair. For example: '13329748:0,20355502:4, 27060221:1'

Table 124-4 (Cont.) SET_FIX_CONTROLS Procedure Parameters

Parameter	Description
sid	The name of the instance on which fix_control setting need to be made. Acceptable values are * or valid instance_name from sys.gv$instance. The default value is *.
scope	The scope of enabling or disabling the installed but disabled execution plan bug fixes. The possible values are: • MEMORY • SPFILE • BOTH The default value is MEMORY.
current_setting_precedence	Precedence of current setting over user supplied setting. The possible values are: • YES–the current environment settings take precedence in case of conflict • NO–input settings take precedence in case of conflict The default value is YES.

Exceptions

The following exceptions are raised by the SET_FIX_CONTROLS Procedure:

- ORA-20001: Bad input value
- ORA-20002: Internal or other errors

125
DBMS_OUTLN

The DBMS_OUTLN package, synonymous with OUTLN_PKG, contains the functional interface for subprograms associated with the management of stored outlines.

> **See Also:**
>
> For more information about using the DBMS_OUTLN package, see *Oracle Database SQL Tuning Guide*.

> **Note:**
>
> Stored outlines will be desupported in a future release in favor of SQL plan management. In Oracle Database 11g Release 1 (11.1), stored outlines continue to function as in past releases. However, Oracle strongly recommends that you use SQL plan management for new applications. SQL plan management creates SQL plan baselines, which offer superior SQL performance and stability compared with stored outlines.If you have existing stored outlines, please consider migrating them to SQL plan baselines by using the LOAD_PLANS_FROM_CURSOR_CACHE Functions or LOAD_PLANS_FROM_SQLSET Function of the DBMS_SPM package. When the migration is complete, you should disable or remove the stored outlines.

This chapter contains the following topics:

- Overview
- Security Model
- Summary of DBMS_OUTLN Subprograms

125.1 DBMS_OUTLN Overview

A stored outline is the stored data that pertains to an execution plan for a given SQL statement. It enables the optimizer to repeatedly re-create execution plans that are equivalent to the plan originally generated along with the outline.The data stored in an outline consists, in part, of a set of hints that are used to achieve plan stability.

Stored outlines will be de-supported in a future release in favor of SQL plan management. As of 11g R1, stored outlines continue to function as in past releases, but Oracle strongly recommends that you use SQL plan management for new applications. SQL plan management creates SQL plan baselines, which offer superior SQL performance and stability compared with stored outlines.If you have existing stored outlines, please consider migrating them to SQL plan baselines by using the LOAD_PLANS_FROM_CURSOR_CACHE Functions or the LOAD_PLANS_FROM_SQLSET Function of the DBMS_SPM package. When the migration is complete, you should disable or remove the stored outlines.

125.2 DBMS_OUTLN Security Model

DBMS_OUTLN contains management procedures that should be available to appropriate users only. EXECUTE privilege is not extended to the general user community unless the DBA explicitly does so.

PL/SQL functions that are available for outline management purposes can be executed only by users with EXECUTE privilege on the procedure (or package).

125.3 Summary of DBMS_OUTLN Subprograms

This table lists the DBMS_OUTLN subprograms and briefly describes them.

Table 125-1 *DBMS_OUTLN Package Subprograms*

Subprogram	Description
CLEAR_USED Procedure	Clears the outline 'used' flag
CREATE_OUTLINE Procedure	Generates outlines from the shared cursor identified by hash value and child number
DROP_BY_CAT Procedure	Drops outlines that belong to a specified category
DROP_UNUSED Procedure	Drops outlines that have never been applied in the compilation of a SQL statement
EXACT_TEXT_SIGNATURES Procedure	Updates outline signatures to those that compute based on exact text matching
UPDATE_BY_CAT Procedure	Changes the category of outlines in one category to a new category
UPDATE_SIGNATURES Procedure	Updates outline signatures to the current version's signature

125.3.1 CLEAR_USED Procedure

This procedure clears the outline 'used' flag.

Syntax

```
DBMS_OUTLN.CLEAR_USED (
   name    IN    VARCHAR2);
```

Parameters

Table 125-2 CLEAR_USED Procedure Parameters

Parameter	Description
name	Name of the outline.

125.3.2 CREATE_OUTLINE Procedure

This procedure generates an outline by reparsing the SQL statement from the shared cursor identified by hash value and child number.

Syntax

```
DBMS_OUTLN.CREATE_OUTLINE (
   hash_value    IN NUMBER,
   child_number  IN NUMBER,
   category      IN VARCHAR2 DEFAULT 'DEFAULT');
```

Parameters

Table 125-3 CREATE_OUTLINE Procedure Parameters

Parameter	Description
`hash_value`	Hash value identifying the target shared cursor.
`child_number`	Child number of the target shared cursor.
`category`	Category in which to create outline (optional).

125.3.3 DROP_BY_CAT Procedure

This procedure drops outlines that belong to a particular category. While outlines are put into the `DEFAULT` category unless otherwise specified, users have the option of grouping their outlines into groups called categories.

Syntax

```
DBMS_OUTLN.DROP_BY_CAT (
   cat VARCHAR2);
```

Parameters

Table 125-4 DROP_BY_CAT Procedure Parameters

Parameter	Description
`cat`	Category of outlines to drop.

Usage Notes

This procedure purges a category of outlines in a single call.

Examples

This example drops all outlines in the `DEFAULT` category:

```
DBMS_OUTLN.DROP_BY_CAT('DEFAULT');
```

125.3.4 DROP_UNUSED Procedure

This procedure drops outlines that have never been applied in the compilation of a SQL statement.

Syntax

```
DBMS_OUTLN.DROP_UNUSED;
```

Usage Notes

You can use `DROP_UNUSED` for outlines generated by an application for one-time use SQL statements created as a result of dynamic SQL. These outlines are never used and take up valuable disk space.

125.3.5 EXACT_TEXT_SIGNATURES Procedure

This procedure updates outline signatures to those that compute based on exact text matching.

Syntax

```
DBMS_OUTLN.EXACT_TEXT_SIGNATURES;
```

Usage Notes

This procedure is relevant only for downgrading an outline to 8.1.6 or earlier.

125.3.6 UPDATE_BY_CAT Procedure

This procedure changes the category of all outlines in one category to a new category.

Syntax

```
DBMS_OUTLN.UPDATE_BY_CAT (
   oldcat    VARCHAR2 default 'DEFAULT',
   newcat    VARCHAR2 default 'DEFAULT');
```

Parameters

Table 125-5 UPDATE_BY_CAT Procedure Parameters

Parameter	Description
`oldcat`	The current category of outlines.
`newcat`	The new category of outlines.

125.3.7 UPDATE_SIGNATURES Procedure

This procedure updates outline signatures to the current version's signature.

Syntax

```
DBMS_OUTLN.UPDATE_SIGNATURES;
```

Usage Notes

You should execute this procedure if you have imported outlines generated in an earlier release to ensure that the signatures are compatible with the current release's computation algorithm.

126
DBMS_OUTPUT

The DBMS_OUTPUT package enables you to send messages from stored procedures, packages, and triggers. The package is especially useful for displaying PL/SQL debugging information.

This chapter contains the following topics:

- Overview
- Security Model
- Operational Notes
- Exceptions
- Rules and Limits
- Examples
- Data Structures
- Summary of DBMS_OUTPUT Subprograms

126.1 DBMS_OUTPUT Overview

The package is typically used for debugging, or for displaying messages and reports to SQL*DBA or SQL*Plus (such as are produced by applying the SQL command DESCRIBE to procedures).

The PUT Procedure and PUT_LINE Procedure in this package enable you to place information in a buffer that can be read by another trigger, procedure, or package. In a separate PL/SQL procedure or anonymous block, you can display the buffered information by calling the GET_LINE Procedure and GET_LINES Procedure.

If the package is disabled, all calls to subprograms are ignored. In this way, you can design your application so that subprograms are available only when a client is able to process the information.

126.2 DBMS_OUTPUT Security Model

The dbmsotpt.sql script must be run as user SYS. This creates the public synonym DBMS_OUTPUT, and EXECUTE permission on this package is granted to public.

126.3 DBMS_OUTPUT Operational Notes

The following operational notes apply to DBMS_OUTPUT.

- If you do not call GET_LINE, or if you do not display the messages on your screen in SQL*Plus, the buffered messages are ignored.
- SQL*Plus calls GET_LINES after issuing a SQL statement or anonymous PL/SQL calls.

- Typing `SET SERVEROUTPUT ON` in SQL*Plus has the effect of invoking

  ```
  DBMS_OUTPUT.ENABLE (buffer_size => NULL);
  ```

  with no limit on the output.
- You should generally avoid having application code invoke either the DISABLE Procedure or ENABLE Procedure because this could subvert the attempt of an external tool like SQL*Plus to control whether or not to display output.

> **Note:**
>
> Messages sent using `DBMS_OUTPUT` are not actually sent until the sending subprogram or trigger completes. There is no mechanism to flush output during the execution of a procedure.

126.4 DBMS_OUTPUT Exceptions

`DBMS_OUTPUT` subprograms raise the application error `ORA-20000` and return errors.

The output procedures can return the following errors:

Table 126-1 DBMS_OUTPUT Errors

Error	Description
`ORU-10027:`	Buffer overflow
`ORU-10028:`	Line length overflow

126.5 DBMS_OUTPUT Rules and Limits

The following are limits on DBMS_OUTPUT line and buffer size.

- The maximum line size is 32767 bytes.
- The default buffer size is 20000 bytes. The minimum size is 2000 bytes and the maximum is unlimited.

126.6 DBMS_OUTPUT Examples

This topic contains three examples of using DBMS_OUTPUT.

Example 1: Using a Trigger to Produce Output

You can use a trigger to print out some output from the debugging process. For example, you could code the trigger to invoke:

```
DBMS_OUTPUT.PUT_LINE('I got here:'||:new.col||' is the new value');
```

If you have enabled the `DBMS_OUTPUT` package, then the text produced by this `PUT_LINE` would be buffered, and you could, after executing the statement (presumably

some INSERT, DELETE, or UPDATE that caused the trigger to fire), retrieve the line of information. For example:

```
BEGIN
   DBMS_OUTPUT.GET_LINE(:buffer, :status);
END;
```

You could then optionally display the buffer on the screen. You repeat calls to GET_LINE until status comes back as nonzero. For better performance, you should use calls to GET_LINES Procedure which can return an array of lines.

Example 2: Debugging Stored Procedures and Triggers

The DBMS_OUTPUT package is commonly used to debug stored procedures and triggers. This package can also be used to enable you to retrieve information about an object and format this output, as shown in "Example 3: Retrieving Information About an Object".

This function queries the employee table and returns the total salary for a specified department. The function includes several calls to the PUT_LINE procedure:

```
CREATE FUNCTION dept_salary (dnum NUMBER) RETURN NUMBER IS
   CURSOR emp_cursor IS
      SELECT sal, comm FROM emp WHERE deptno = dnum;
   total_wages    NUMBER(11, 2) := 0;
   counter        NUMBER(10) := 1;
BEGIN

   FOR emp_record IN emp_cursor LOOP
      emp_record.comm := NVL(emp_record.comm, 0);
      total_wages := total_wages + emp_record.sal
         + emp_record.comm;
      DBMS_OUTPUT.PUT_LINE('Loop number = ' || counter ||
         '; Wages = '|| TO_CHAR(total_wages));    /* Debug line */
      counter := counter + 1; /* Increment debug counter */
   END LOOP;
   /* Debug line */
   DBMS_OUTPUT.PUT_LINE('Total wages = ' ||
     TO_CHAR(total_wages));
   RETURN total_wages;

END dept_salary;
```

Assume the EMP table contains the following rows:

```
EMPNO          SAL     COMM     DEPT
-----        ------- -------- -------
1002           1500      500      20
1203           1000               30
1289           1000               10
1347           1000      250      20
```

Assume the user executes the following statements in SQL*Plus:

```
SET SERVEROUTPUT ON
VARIABLE salary NUMBER;
EXECUTE :salary := dept_salary(20);
```

The user would then see the following information displayed in the output pane:

```
Loop number = 1; Wages = 2000
Loop number = 2; Wages = 3250
```

```
Total wages = 3250

PL/SQL procedure successfully executed.
```

Example 3: Retrieving Information About an Object

In this example, the user has used the `EXPLAIN PLAN` command to retrieve information about the execution plan for a statement and has stored it in `PLAN_TABLE`. The user has also assigned a statement ID to this statement. The example `EXPLAIN_OUT` procedure retrieves the information from this table and formats the output in a nested manner that more closely depicts the order of steps undergone in processing the SQL statement.

```
 /*****************************************************************/
/* Create EXPLAIN_OUT procedure. User must pass STATEMENT_ID to */
/* to procedure, to uniquely identify statement.                 */
/*****************************************************************/
CREATE OR REPLACE PROCEDURE explain_out
   (statement_id IN VARCHAR2) AS

   -- Retrieve information from PLAN_TABLE into cursor EXPLAIN_ROWS.

   CURSOR explain_rows IS
      SELECT level, id, position, operation, options,
         object_name
      FROM plan_table
      WHERE statement_id = explain_out.statement_id
      CONNECT BY PRIOR id = parent_id
         AND statement_id = explain_out.statement_id
      START WITH id = 0
       ORDER BY id;

BEGIN

   -- Loop through information retrieved from PLAN_TABLE:

   FOR line IN explain_rows LOOP

      -- At start of output, include heading with estimated cost.

      IF line.id = 0 THEN
         DBMS_OUTPUT.PUT_LINE ('Plan for statement '
            || statement_id
            || ', estimated cost = ' || line.position);
      END IF;

      -- Output formatted information. LEVEL determines indention level.

      DBMS_OUTPUT.PUT_LINE (lpad(' ',2*(line.level-1)) ||
         line.operation || ' ' || line.options || ' ' ||
         line.object_name);
   END LOOP;

END;
```

> UTL_FILE

126.7 DBMS_OUTPUT Data Structures

The DBMS_OUTPUT package declares 2 collection types for use with the GET_LINES Procedure.

TABLE Types

CHARARR Table Type

OBJECT Types

DBMSOUTPUT_LINESARRAY Object Type

Related Topics

- GET_LINES Procedure
  This procedure retrieves an array of lines from the buffer.

126.7.1 CHARARR Table Type

This package type is to be used with the GET_LINES Procedure to obtain text submitted through the PUT Procedure and PUT_LINE Procedure.

Syntax

```
TYPE CHARARR IS TABLE OF VARCHAR2(32767) INDEX BY BINARY_INTEGER;
```

Related Topics

- GET_LINES Procedure
  This procedure retrieves an array of lines from the buffer.
- PUT Procedure
  This procedure places a partial line in the buffer.
- PUT_LINE Procedure
  This procedure places a line in the buffer.

126.7.2 DBMS_OUTPUT DBMSOUTPUT_LINESARRAY Object Type

This type, defined outside the package, is to be used with the GET_LINES Procedure to obtain text submitted through the PUT Procedure and PUT_LINE Procedure.

Syntax

```
TYPE DBMSOUTPUT_LINESARRAY IS
     VARRAY(2147483647) OF VARCHAR2(32767);
```

Related Topics

- GET_LINES Procedure
  This procedure retrieves an array of lines from the buffer.
- PUT Procedure
  This procedure places a partial line in the buffer.
- PUT_LINE Procedure
  This procedure places a line in the buffer.

126.8 Summary of DBMS_OUTPUT Subprograms

This table lists the DBMS_OUTPUT subprograms and briefly describes them.

Table 126-2 DBMS_OUTPUT Package Subprograms

Subprogram	Description
DISABLE Procedure	Disables message output
ENABLE Procedure	Enables message output
GET_LINE Procedure	Retrieves one line from buffer
GET_LINES Procedure	Retrieves an array of lines from buffer
NEW_LINE Procedure	Terminates a line created with PUT
PUT Procedure	Places a partial line in the buffer
PUT_LINE Procedure	Places line in buffer

> **Note:**
>
> The PUT Procedure that take a number are obsolete and, while currently supported, are included in this release for legacy reasons only.

126.8.1 DISABLE Procedure

This procedure disables calls to PUT, PUT_LINE, NEW_LINE, GET_LINE, and GET_LINES, and purges the buffer of any remaining information.

As with the ENABLE Procedure, you do not need to call this procedure if you are using the SERVEROUTPUT option of SQL*Plus.

Syntax

```
DBMS_OUTPUT.DISABLE;
```

Pragmas

```
pragma restrict_references(disable,WNDS,RNDS);
```

126.8.2 ENABLE Procedure

This procedure enables calls to PUT, PUT_LINE, NEW_LINE, GET_LINE, and GET_LINES.

Calls to these procedures are ignored if the DBMS_OUTPUT package is not activated.

Syntax

```
DBMS_OUTPUT.ENABLE (
   buffer_size IN INTEGER DEFAULT 20000);
```

Pragmas

```
pragma restrict_references(enable,WNDS,RNDS);
```

Parameters

Table 126-3 ENABLE Procedure Parameters

Parameter	Description
buffer_size	Upper limit, in bytes, the amount of buffered information. Setting buffer_size to NULL specifies that there should be no limit.

Usage Notes

- It is not necessary to call this procedure when you use the SET SERVEROUTPUT option of SQL*Plus.
- If there are multiple calls to ENABLE, then buffer_size is the last of the values specified. The maximum size is 1,000,000, and the minimum is 2,000 when the user specifies buffer_size (NOT NULL).
- NULL is expected to be the usual choice. The default is 20,000 for backwards compatibility with earlier database versions that did not support unlimited buffering.

126.8.3 GET_LINE Procedure

This procedure retrieves a single line of buffered information.

Syntax

```
DBMS_OUTPUT.GET_LINE (
   line    OUT VARCHAR2,
   status  OUT INTEGER);
```

Parameters

Table 126-4 GET_LINE Procedure Parameters

Parameter	Description
line	Returns a single line of buffered information, excluding a final newline character. You should declare the actual for this parameter as VARCHAR2 (32767) to avoid the risk of "ORA-06502: PL/SQL: numeric or value error: character string buffer too small".
status	If the call completes successfully, then the status returns as 0. If there are no more lines in the buffer, then the status is 1.

Usage Notes

- You can choose to retrieve from the buffer a single line or an array of lines. Call the GET_LINE procedure to retrieve a single line of buffered information. To reduce the number of calls to the server, call the GET_LINES procedure to retrieve an array of lines from the buffer.

- You can choose to automatically display this information if you are using SQL*Plus by using the special `SET SERVEROUTPUT ON` command.
- After calling `GET_LINE` or `GET_LINES`, any lines not retrieved before the next call to `PUT`, `PUT_LINE`, or `NEW_LINE` are discarded to avoid confusing them with the next message.

126.8.4 GET_LINES Procedure

This procedure retrieves an array of lines from the buffer.

Syntax

```
DBMS_OUTPUT.GET_LINES (
   lines       OUT     CHARARR,
   numlines    IN OUT  INTEGER);

DBMS_OUTPUT.GET_LINES (
   lines       OUT     DBMSOUTPUT_LINESARRAY,
   numlines    IN OUT INTEGER);
```

Parameters

Table 126-5 GET_LINES Procedure Parameters

Parameter	Description
`lines`	Returns an array of lines of buffered information. The maximum length of each line in the array is 32767 bytes. It is recommended that you use the VARRAY overload version in a 3GL host program to execute the procedure from a PL/SQL anonymous block.
`numlines`	Number of lines you want to retrieve from the buffer. After retrieving the specified number of lines, the procedure returns the number of lines actually retrieved. If this number is less than the number of lines requested, then there are no more lines in the buffer.

Usage Notes

- You can choose to retrieve from the buffer a single line or an array of lines. Call the `GET_LINE` procedure to retrieve a single line of buffered information. To reduce the number of calls to the server, call the `GET_LINES` procedure to retrieve an array of lines from the buffer.
- You can choose to automatically display this information if you are using SQL*Plus by using the special `SET SERVEROUTPUT ON` command.
- After calling `GET_LINE` or `GET_LINES`, any lines not retrieved before the next call to `PUT`, `PUT_LINE`, or `NEW_LINE` are discarded to avoid confusing them with the next message.

126.8.5 NEW_LINE Procedure

This procedure puts an end-of-line marker.

The GET_LINE Procedure and the GET_LINES Procedure return "lines" as delimited by "newlines". Every call to the PUT_LINE Procedure or NEW_LINE Procedure generates a line that is returned by `GET_LINE(S)`.

Syntax

```
DBMS_OUTPUT.NEW_LINE;
```

126.8.6 PUT Procedure

This procedure places a partial line in the buffer.

> **Note:**
>
> The `PUT` procedure that takes a `NUMBER` is obsolete and, while currently supported, is included in this release for legacy reasons only.

Syntax

```
DBMS_OUTPUT.PUT (
    item IN VARCHAR2);
```

Parameters

Table 126-6 PUT Procedure Parameters

Parameter	Description
`item`	Item to buffer.

Exceptions

Table 126-7 PUT Procedure Exceptions

Error	Description
`ORA-20000, ORU-10027:`	Buffer overflow, limit of <`buf_limit`> bytes.
`ORA-20000, ORU-10028:`	Line length overflow, limit of 32767 bytes for each line.

Usage Notes

- You can build a line of information piece by piece by making multiple calls to `PUT`, or place an entire line of information into the buffer by calling `PUT_LINE`.
- When you call `PUT_LINE` the item you specify is automatically followed by an end-of-line marker. If you make calls to `PUT` to build a line, then you must add your own end-of-line

marker by calling NEW_LINE. GET_LINE and GET_LINES do not return lines that have not been terminated with a newline character.

- If your lines exceed the line limit, you receive an error message.
- Output that you create using PUT or PUT_LINE is buffered. The output cannot be retrieved until the PL/SQL program unit from which it was buffered returns to its caller.

  For example, SQL*Plus does not display DBMS_OUTPUT messages until the PL/SQL program completes. There is no mechanism for flushing the DBMS_OUTPUT buffers within the PL/SQL program.

```
SQL> SET SERVEROUTPUT ON
SQL> BEGIN
  2  DBMS_OUTPUT.PUT_LINE ('hello');
  3  DBMS_LOCK.SLEEP (10);
  4  END;
```

126.8.7 PUT_LINE Procedure

This procedure places a line in the buffer.

> **Note:**
>
> The PUT_LINE procedure that takes a NUMBER is obsolete and, while currently supported, is included in this release for legacy reasons only.

Syntax

```
DBMS_OUTPUT.PUT_LINE (
   item IN VARCHAR2);
```

Parameters

Table 126-8 PUT_LINE Procedure Parameters

Parameter	Description
item	Item to buffer.

Exceptions

Table 126-9 PUT_LINE Procedure Exceptions

Error	Description
ORA-20000, ORU-10027:	Buffer overflow, limit of <buf_limit> bytes.
ORA-20000, ORU-10028:	Line length overflow, limit of 32767 bytes for each line.

Usage Notes

- You can build a line of information piece by piece by making multiple calls to `PUT`, or place an entire line of information into the buffer by calling `PUT_LINE`.
- When you call `PUT_LINE` the item you specify is automatically followed by an end-of-line marker. If you make calls to `PUT` to build a line, then you must add your own end-of-line marker by calling `NEW_LINE`. `GET_LINE` and `GET_LINES` do not return lines that have not been terminated with a newline character.
- If your lines exceeds the line limit, you receive an error message.
- Output that you create using `PUT` or `PUT_LINE` is buffered. The output cannot be retrieved until the PL/SQL program unit from which it was buffered returns to its caller.

  For example, SQL*Plus does not display `DBMS_OUTPUT` messages until the PL/SQL program completes. There is no mechanism for flushing the `DBMS_OUTPUT` buffers within the PL/SQL program. For example:

```
SQL> SET SERVEROUTPUT ON
SQL> BEGIN
   2 DBMS_OUTPUT.PUT_LINE ('hello');
   3 DBMS_LOCK.SLEEP (10);
   4 END;
```

DBMS_PARALLEL_EXECUTE

The DBMS_PARALLEL_EXECUTE package enables incremental update of table data in parallel.

This chapter contains the following topics:

- Overview
- Security Model
- Constants
- Views
- Exceptions
- Examples
- Summary of DBMS_PARALLEL_EXECUTE Subprograms

> **See Also:**
>
> - *Oracle Database Development Guide*
> - *Oracle Database Reference*

127.1 DBMS_PARALLEL_EXECUTE Overview

This package lets you incrementally update table data in parallel, in two high-level steps.

1. Group sets of rows in the table into smaller-sized chunks.
2. Run a user-specified statement on these chunks in parallel, and commit when finished processing each chunk.

This package introduces the notion of *parallel execution task*. This task groups the various steps associated with the parallel execution of a PL/SQL block, which is typically updating table data.

All of the package subroutines (except the GENERATE_TASK_NAME Function and the TASK_STATUS Procedure) perform a commit.

127.2 DBMS_PARALLEL_EXECUTE Security Model

DBMS_PARALLEL_EXECUTE is a SYS-owned package which is granted to PUBLIC.

Users who have the ADM_PARALLEL_EXECUTE_TASK role can perform administrative routines (qualified by the prefix ADM_) and access the DBA view.

Apart from the administrative routines, all the subprograms refer to tasks owned by the current user.

To execute chunks in parallel, you must have `CREATE JOB` system privilege.

The `CHUNK_BY_SQL`, `RUN_TASK`, and `RESUME_TASK` subprograms require a query, and are executed using `DBMS_SQL`. Invokers of the `DBMS_SQL` interface must ensure that no query contains SQL injection.

127.3 DBMS_PARALLEL_EXECUTE Constants

The `DBMS_PARALLEL_EXECUTE` package uses the constants described in these two tables.

Table 127-1 DBMS_PARALLEL_EXECUTE Constants - Chunk Status Value

Constant	Type	Value	Description
`ASSIGNED`	`NUMBER`	1	Chunk has been assigned for processing
`PROCESSED`	`NUMBER`	2	Chunk has been processed successfully
`PROCESSED_WITH_ERROR`	`NUMBER`	3	Chunk has been processed, but an error occurred during processing
`UNASSIGNED`	`NUMBER`	0	Chunk is unassigned

Table 127-2 DBMS_PARALLEL_EXECUTE Constants - Task Status Value

Constant	Type	Value	Description
`CHUNKED`	`NUMBER`	5	Table associated with the task has been chunked, but none of the chunk has been assigned for processing
`CHUNKING`	`NUMBER`	2	Table associated with the task is being chunked
`CHUNKING_FAILED`	`NUMBER`	3	Chunking failed
`CRASHED`	`NUMBER`	9	Only applicable if parallel execution is used, this occurs if a job slave crashes or if the database crashes during `EXECUTE`, leaving a chunk in `ASSIGNED` or `UNASSIGNED` state.
`CREATED`	`NUMBER`	1	The task has been created by the CREATE_TASK Procedure
`FINISHED`	`NUMBER`	7	All chunks processed without error
`FINISHED_WITH_ERROR`	`NUMBER`	8	All chunks processed, but with errors in some cases
`NO_CHUNKS`	`NUMBER`	4	Table associated with the task has no chunks created
`PROCESSING`	`NUMBER`	6	Part of the chunk assigned for processing, or which has been processed

> **Note:**
>
> Use constants instead of absolute values, because absolute values might change in future.

127.4 DBMS_PARALLEL_EXECUTE Views

The `DBMS_PARALLEL_EXECUTE` package uses the following views.

- DBA_PARALLEL_EXECUTE_CHUNKS
- DBA_PARALLEL_EXECUTE_TASKS
- USER_PARALLEL_EXECUTE_CHUNKS
- USER_PARALLEL_EXECUTE_TASKS

127.5 DBMS_PARALLEL_EXECUTE Exceptions

The following table lists the exceptions raised by `DBMS_PARALLEL_EXECUTE`.

Table 127-3 Exceptions Raised by DBMS_PARALLEL_EXECUTE

Exception	Error Code	Description
`CHUNK_NOT_FOUND`	29499	Specified chunk does not exist
`DUPLICATE_TASK_NAME`	29497	Same task name has been used by an existing task
`INVALID_STATE_FOR_CHUNK`	29492	Attempts to chunk a table that is not in `CREATED` or `CHUNKING_FAILED` state
`INVALID_STATE_FOR_RESUME`	29495	Attempts to resume execution, but the task is not in `FINISHED_WITH_ERROR` or `CRASHED` state
`INVALID_STATE_FOR_RUN`	29494	Attempts to execute the task that is not in `CHUNKED` state
`INVALID_STATUS`	29493	Attempts to set an invalid value to the chunk status
`INVALID_TABLE`	29491	Attempts to chunk a table by rowid in cases in which the table is not a physical table, or the table is an IOT
`MISSING_ROLE`	29490	User does not have the necessary `ADM_PARALLEL_EXECUTE` role
`TASK_NOT_FOUND`	29498	Specified `task_name` does not exist

127.6 DBMS_PARALLEL_EXECUTE Examples

The following examples run on the Human Resources (HR) schema of the Oracle Database Sample Schemas. They requires that the HR schema be created with the `JOB SYSTEM` privilege.

Chunk by ROWID

This example shows the most common usage of this package. After calling the RUN_TASK Procedure, it checks for errors and reruns in the case of error.

```
DECLARE
  l_sql_stmt VARCHAR2(1000);
  l_try NUMBER;
  l_status NUMBER;
BEGIN

  -- Create the TASK
  DBMS_PARALLEL_EXECUTE.CREATE_TASK ('mytask');

  -- Chunk the table by ROWID
  DBMS_PARALLEL_EXECUTE.CREATE_CHUNKS_BY_ROWID('mytask', 'HR', 'EMPLOYEES',
true, 100);

  -- Execute the DML in parallel
  l_sql_stmt := 'update EMPLOYEES e
      SET e.salary = e.salary + 10
      WHERE rowid BETWEEN :start_id AND :end_id';
  DBMS_PARALLEL_EXECUTE.RUN_TASK('mytask', l_sql_stmt, DBMS_SQL.NATIVE,
                                 parallel_level => 10);

  -- If there is an error, RESUME it for at most 2 times.
  L_try := 0;
  L_status := DBMS_PARALLEL_EXECUTE.TASK_STATUS('mytask');
  WHILE(l_try < 2 and L_status != DBMS_PARALLEL_EXECUTE.FINISHED)
  LOOP
    L_try := l_try + 1;
    DBMS_PARALLEL_EXECUTE.RESUME_TASK('mytask');
    L_status := DBMS_PARALLEL_EXECUTE.TASK_STATUS('mytask');
  END LOOP;

  -- Done with processing; drop the task
  DBMS_PARALLEL_EXECUTE.DROP_TASK('mytask');

END;
/
```

Chunk by User-Provided SQL

A user can specify a chunk algorithm by using the CREATE_CHUNKS_BY_SQL Procedure. This example shows that rows with the same `manager_id` are grouped together and processed in one chunk.

```
DECLARE
  l_chunk_sql VARCHAR2(1000);
  l_sql_stmt VARCHAR2(1000);
  l_try NUMBER;
  l_status NUMBER;
BEGIN

  -- Create the TASK
  DBMS_PARALLEL_EXECUTE.CREATE_TASK ('mytask');

  -- Chunk the table by MANAGER_ID
  l_chunk_sql := 'SELECT distinct manager_id, manager_id FROM employees';
  DBMS_PARALLEL_EXECUTE.CREATE_CHUNKS_BY_SQL('mytask', l_chunk_sql, false);

  -- Execute the DML in parallel
  --   the WHERE clause contain a condition on manager_id, which is the chunk
  --   column. In this case, grouping rows is by manager_id.
  l_sql_stmt := 'update EMPLOYEES e
      SET e.salary = e.salary + 10
```

```
      WHERE manager_id between :start_id and :end_id';
  DBMS_PARALLEL_EXECUTE.RUN_TASK('mytask', l_sql_stmt, DBMS_SQL.NATIVE,
                                 parallel_level => 10);

  -- If there is error, RESUME it for at most 2 times.
  L_try := 0;
  L_status := DBMS_PARALLEL_EXECUTE.TASK_STATUS('mytask');
  WHILE(l_try < 2 and L_status != DBMS_PARALLEL_EXECUTE.FINISHED)
  Loop
    L_try := l_try + 1;
    DBMS_PARALLEL_EXECUTE.RESUME_TASK('mytask');
    L_status := DBMS_PARALLEL_EXECUTE.TASK_STATUS('mytask');
  END LOOP;

  -- Done with processing; drop the task
  DBMS_PARALLEL_EXECUTE.DROP_TASK('mytask');

end;
/
```

Executing Chunks in an User-defined Framework

You can execute chunks in a self-defined framework without using the RUN_TASK Procedure. This example shows how to use GET_ROWID_CHUNK Procedure, `EXECUTE IMMEDIATE`, SET_CHUNK_STATUS Procedure to execute the chunks.

```
DECLARE
  l_sql_stmt varchar2(1000);
  l_try number;
  l_status number;
  l_chunk_id number;
  l_start_rowid rowid;
  l_end_rowid rowid;
  l_any_rows boolean;
  CURSOR c1 IS SELECT chunk_id
               FROM user_parallel_execute_chunks
               WHERE task_name = 'mytask'
                 AND STATUS IN (DBMS_PARALLEL_EXECUTE.PROCESSED_WITH_ERROR,
                                DBMS_PARALLEL_EXECUTE.ASSIGNED);
BEGIN

  -- Create the Objects, task, and chunk by ROWID
  DBMS_PARALLEL_EXECUTE.CREATE_TASK ('mytask');
  DBMS_PARALLEL_EXECUTE.CREATE_CHUNKS_BY_ROWID('mytask', 'HR', 'EMPLOYEES', true, 100);

  l_sql_stmt := 'update EMPLOYEES e
      SET e.salary = e.salary + 10
      WHERE rowid BETWEEN :start_id AND :end_id';

  -- Execute the DML in his own framework
  --
  -- Process each chunk and commit.
  -- After processing one chunk, repeat this process until
  -- all the chunks are processed.
  --
  <<main_processing>>
  LOOP
      --
      -- Get a chunk to process; if there is nothing to process, then exit the
      -- loop;
      --
```

```
    DBMS_PARALLEL_EXECUTE.GET_ROWID_CHUNK('mytask',
                                                        l_chunk_id,
                                                        l_start_rowid,
                                                        l_end_rowid,
                                                        l_any_rows);
    IF (l_any_rows = false) THEN EXIT; END IF;

    --
    -- The chunk is specified by start_id and end_id.
    -- Bind the start_id and end_id and then execute it
    --
    -- If no error occured, set the chunk status to PROCESSED.
    --
    -- Catch any exception. If an exception occured, store the error num/msg
    -- into the chunk table and then continue to process the next chunk.
    --
    BEGIN
      EXECUTE IMMEDIATE l_sql_stmt using l_start_rowid, l_end_rowid;
      DBMS_PARALLEL_EXECUTE.SET_CHUNK_STATUS('mytask',l_chunk_id,
        DBMS_PARALLEL_EXECUTE.PROCESSED);
    EXCEPTION WHEN OTHERS THEN
      DBMS_PARALLEL_EXECUTE.SET_CHUNK_STATUS('mytask', l_chunk_id,
        DBMS_PARALLEL_EXECUTE.PROCESSED_WITH_ERROR, SQLCODE, SQLERRM);
    END;

    --
    -- Finished processing one chunk; Commit here
    --
    COMMIT;
  END LOOP;
```

127.7 Summary of DBMS_PARALLEL_EXECUTE Subprograms

This table lists the `DBMS_PARALLEL_EXECUTE` subprograms and briefly describes them.

Table 127-4 DBMS_PARALLEL_EXECUTE Package Subprograms

Subprogram	Description
ADM_DROP_CHUNKS Procedure	Drops all chunks of the specified task owned by the specified owner
ADM_DROP_TASK Procedure	Drops the task of the given user and all related chunks
ADM_TASK_STATUS Function	Returns the task status
ADM_STOP_TASK Procedure	Stops the task of the given owner and related job slaves
CREATE_TASK Procedure	Creates a task for the current user
CREATE_CHUNKS_BY_NUMBER_COL Procedure	Chunks the table associated with the given task by the specified column.
CREATE_CHUNKS_BY_ROWID Procedure	Chunks the table associated with the given task by `ROWID`
CREATE_CHUNKS_BY_SQL Procedure	Chunks the table associated with the given task by means of a user-provided `SELECT` statement
DROP_TASK Procedure	Drops the task and all related chunks

Table 127-4 (Cont.) DBMS_PARALLEL_EXECUTE Package Subprograms

Subprogram	Description
DROP_CHUNKS Procedure	Drops the task's chunks
GENERATE_TASK_NAME Function	Returns a unique name for a task
GET_NUMBER_COL_CHUNK Procedure	Picks an unassigned `NUMBER` chunk and changes it to `ASSIGNED`
GET_ROWID_CHUNK Procedure	Picks an unassigned `ROWID` chunk and changes it to `ASSIGNED`
PURGE_PROCESSED_CHUNKS Procedure	Deletes all the processed chunks whose status is `PROCESSED` or `PROCESSED_WITH_ERROR`
RESUME_TASK Procedures	Retries the given the task if the RUN_TASK Procedure finished with an error, or resumes the task if a crash occurred.
RUN_TASK Procedure	Executes the specified SQL statement on the chunks in parallel
SET_CHUNK_STATUS Procedure	Sets the status of the chunk
STOP_TASK Procedure	Stops the task and related job slaves
TASK_STATUS Procedure	Returns the task status

127.7.1 ADM_DROP_CHUNKS Procedure

This procedure drops all chunks of the specified task owned by the specified owner.

Syntax

```
DBMS_PARALLEL_EXECUTE.ADM_DROP_CHUNKS (
   task_owner      IN  VARCHAR2,
   task_name       IN  VARCHAR2);
```

Parameters

Table 127-5 ADM_DROP_CHUNKS Procedure Parameters

Parameter	Description
`task_owner`	Owner of the task
`task_name`	Name of the task

127.7.2 ADM_DROP_TASK Procedure

This procedure drops the task of the specified user and all related chunks.

Syntax

```
DBMS_PARALLEL_EXECUTE.ADM_DROP_TASK (
   task_owner      IN  VARCHAR2,
   task_name       IN  VARCHAR2);
```

Parameters

Table 127-6 ADM_DROP_TASK Procedure Parameters

Parameter	Description
task_owner	Owner of the task
task_name	Name of the task

127.7.3 ADM_TASK_STATUS Function

This function returns the task status.

Syntax

```
DBMS_PARALLEL_EXECUTE.ADM_TASK_STATUS  (
   task_owner      IN  VARCHAR2,
   task_name       IN  VARCHAR2)
 RETURN NUMBER;
```

Parameters

Table 127-7 ADM_TASK_STATUS Function Parameters

Parameter	Description
task_owner	Owner of the task
task_name	Name of the task

127.7.4 ADM_STOP_TASK Procedure

This procedure stops the task of the specified owner and related job slaves.

Syntax

```
DBMS_PARALLEL_EXECUTE.ADM_STOP_TASK (
   task_owner      IN  VARCHAR2,
   task_name       IN  VARCHAR2);
```

Parameters

Table 127-8 ADM_STOP_TASK Procedure Parameters

Parameter	Description
task_owner	Owner of the task
task_name	Name of the task

127.7.5 CREATE_TASK Procedure

This procedure creates a task for the current user. The pairing of `task_name` and `current_user` must be unique.

Syntax

```
DBMS_PARALLEL_EXECUTE.CREATE_TASK (
   task_name        IN   VARCHAR2,
   comment          IN   VARCHAR2 DEFAULT NULL);
```

Parameters

Table 127-9 CREATE_TASK Procedure Parameters

Parameter	Description
`task_name`	Name of the task. The task_name can be any string in which related length must be less than or equal to 128 bytes.
`comment`	Comment field. The comment must be less than 4000 bytes.

127.7.6 CREATE_CHUNKS_BY_NUMBER_COL Procedure

This procedure chunks the table (associated with the specified task) by the specified column. The specified column must be a `NUMBER` column. This procedure takes the `MIN` and `MAX` value of the column, and then divides the range evenly according to `chunk_size`.

The chunks are:

```
START_ID                          END_ID
--------------------------        --------------------------
min_id_val                        min_id_val+1*chunk_size-1
min_id_val+1*chunk_size           min_id_val+2*chunk_size-1
…                                 …
min_id_val+i*chunk_size           max_id_val
```

Syntax

```
DBMS_PARALLEL_EXECUTE.CREATE_CHUNKS_BY_NUMBER_COL (
   task_name       IN  VARCHAR2,
   table_owner     IN  VARCHAR2,
   table_name      IN  VARCHAR2,
   table_column    IN  VARCHAR2,
   chunk_size      IN  NUMBER);
```

Parameters

Table 127-10 CREATE_CHUNKS_BY_NUMBER_COL Procedure Parameters

Parameter	Description
`task_name`	Name of the task
`table_owner`	Owner of the table
`table_name`	Name of the table

Table 127-10 (Cont.) CREATE_CHUNKS_BY_NUMBER_COL Procedure Parameters

Parameter	Description
table_column	Name of the NUMBER column
chunk_size	Range of each chunk

127.7.7 CREATE_CHUNKS_BY_ROWID Procedure

This procedure chunks the table (associated with the specified task) by ROWID.

num_row and num_block are approximate guidance for the size of each chunk. The table to be chunked must be a physical table with physical ROWID having views and table functions. Index-organized tables are not allowed.

Syntax

```
DBMS_PARALLEL_EXECUTE.CREATE_CHUNKS_BY_ROWID (
   task_name       IN  VARCHAR2,
   table_owner     IN  VARCHAR2,
   table_name      IN  VARCHAR2,
   by_row          IN  BOOLEAN,
   chunk_size      IN  NUMBER);
```

Parameters

Table 127-11 CREATE_CHUNKS_BY_ROWID Procedure Parameters

Parameter	Description
task_name	Name of the task
table_owner	Owner of the table
table_name	Name of the table
by_row	TRUE if chunk_size refers to the number of rows, otherwise, chunk_size refers to the number of blocks
chunk_size	Approximate number of rows/blocks to process for each commit cycle

127.7.8 CREATE_CHUNKS_BY_SQL Procedure

This procedure chunks the table (associated with the specified task) by means of a user-provided SELECT statement.

The SELECT statement that returns the range of each chunk must have two columns: start_id and end_id. If the task is to chunk by ROWID, then the two columns must be of ROWID type. If the task is to chunk the table by NUMBER column, then the two columns must be of NUMBER type. The procedure provides the flexibility to users who want to deploy user-defined chunk algorithms.

Syntax

```
DBMS_PARALLEL_EXECUTE.CREATE_CHUNKS_BY_SQL (
   task_name       IN  VARCHAR2,
```

```
   sql_stmt        IN  CLOB,
   by_rowid        IN  BOOLEAN);
```

Parameters

Table 127-12 CREATE_CHUNKS_BY_SQL Procedure Parameters

Parameter	Description
task_name	Name of the task
sql_stmt	SQL that returns the chunk ranges
by_rowid	TRUE if the table is chunked by rowids

127.7.9 DROP_TASK Procedure

This procedure drops the task and all related chunks.

Syntax

```
DBMS_PARALLEL_EXECUTE.DROP_TASK (
   task_name       IN VARCHAR2);
```

Parameters

Table 127-13 DROP_TASK Procedure Parameters

Parameter	Description
task_name	Name of the task

127.7.10 DROP_CHUNKS Procedure

This procedure drops the task's chunks.

Syntax

```
DBMS_PARALLEL_EXECUTE.DROP_CHUNKS (
   task_name       IN VARCHAR2);
```

Parameters

Table 127-14 DROP_CHUNKS Procedure Parameters

Parameter	Description
task_name	Name of the task

127.7.11 GENERATE_TASK_NAME Function

This function returns a unique name for a task.

The name is of the form *prefix*N where N is a number from a sequence. If no prefix is specified, the generated name is, by default, TASK$_1, TASK$_2, TASK$_3, and so on. If 'SCOTT' is specified as the prefix, the name is SCOTT1, SCOTT2, and so on.

Syntax

```
DBMS_PARALLEL_EXECUTE.GENERATE_TASK_NAME (
   prefix      IN      VARCHAR2 DEFAULT 'TASK$_')
 RETURN VARCHAR2;
```

Parameters

Table 127-15 GENERATE_TASK_NAME Function Parameters

Parameter	Description
`prefix`	The prefix to use when generating the task name

127.7.12 GET_NUMBER_COL_CHUNK Procedure

This procedure picks an unassigned `NUMBER` chunk and changes it to `ASSIGNED`. If there are no more chunks to assign, `any_rows` is set to `FALSE`. Otherwise, the `chunk_id`, `start`, and `end_id` of the chunk are returned as `OUT` parameters.

The chunk information in `DBMS_PARALLEL_EXECUTE_CHUNKS$` is updated as follows: `STATUS` becomes `ASSIGNED`; `START_TIMESTAMP` records the current time; `END_TIMESTAMP` is cleared.

> **See Also:**
>
> Views

Syntax

```
DBMS_PARALLEL_EXECUTE.GET_NUMBER_COL_CHUNK (
   task_name       IN VARCHAR2,
   chunk_id        OUT NUMBER,
   start_id        OUT NUMBER,
   end_id          OUT NUMBER,
   any_rows        OUT BOOLEAN);
```

Parameters

Table 127-16 GET_NUMBER_COL_CHUNK Procedure Parameters

Parameter	Description
`task_name`	Name of the task
`chunk_id`	Chunk ID of the chunk
`start_id`	ID of the start row in the returned range
`end_id`	ID of the end row in the returned range
`any_rows`	Indicates if there could be any rows to process in the range

Usage Notes

If the task is chunked by `ROWID`, then use `get_rowid_range`. If the task is chunked by `NUMBER` column, then use `get_number_col_range`. If you make the wrong function call, the returning `chunk_id` and `any_rows` have valid values but `start_id` and `end_id` are `NULL`.

127.7.13 GET_ROWID_CHUNK Procedure

This procedure picks an unassigned `ROWID` chunk and changes it to `ASSIGNED`.

If there are no more chunks to assign, `any_rows` is set to `FALSE`. Otherwise, the `chunk_id`, `start`, and `end_rowid` of the chunk are returned as `OUT` parameters. The chunk info in `DBMS_PARALLEL_EXECUTE_CHUNKS$` is updated as follows: `STATUS` becomes `ASSIGNED`; `START_TIMESTAMP` records the current time; `END_TIMESTAMP` is cleared.

> **See Also:**
>
> Views

Syntax

```
DBMS_PARALLEL_EXECUTE.GET_ROWID_CHUNK (
   task_name       IN VARCHAR2,
   chunk_id        OUT NUMBER,
   start_rowid     OUT ROWID,
   end_rowid       OUT ROWID,
   any_rows        OUT BOOLEAN);
```

Parameters

Table 127-17 GET_ROWID_CHUNK Procedure Parameters

Parameter	Description
`task_name`	Name of the task
`chunk_id`	Chunk ID of the chunk
`start_rowid`	Start rowid in the returned range
`end_rowid`	End rowid in the returned range
`any_rows`	Indicates that the range could include rows to process

Usage Notes

If the task is chunked by `ROWID`, then use `get_rowid_range`. If the task is chunked by `NUMBER` column, then use `get_number_col_range`. If you make the wrong function call, the returning `chunk_id` and `any_rows` will still have valid values but `start_id` and `end_id` are `NULL`.

127.7.14 PURGE_PROCESSED_CHUNKS Procedure

This procedure deletes all the processed chunks whose status is `PROCESSED` or `PROCESSED_WITH_ERROR`.

Syntax

```
DBMS_PARALLEL_EXECUTE.PURGE_PROCESSED_CHUNKS (
   task_name       IN VARCHAR2);
```

Parameters

Table 127-18 PURGE_PROCESSED_CHUNKS Procedure Parameters

Parameter	Description
`task_name`	Name of the task

127.7.15 RESUME_TASK Procedures

This procedure retries the specified the task if the RUN_TASK Procedure finished with an error, or resumes the task if a crash occurred.

You can only invoke this procedure if the task is in a `CRASHED` or `FINISHED_WITH_ERROR` state.

For a crashed serial execution, the state remains in `PROCESSING`. The `FORCE` option allows you to resume any task in `PROCESSING` state. However, it is your responsibility to determine that a crash has occurred.

The procedure resumes processing the chunks which have not been processed. Also, chunks which are in `PROCESSED_WITH_ERROR` or `ASSIGNED` (due to crash) state are processed because those chunks did not commit.

This procedure takes the same argument as the RUN_TASK Procedure. The overload which takes `task_name` as the only input argument re-uses the arguments provided in the previous invoking of the RUN_TASK Procedure or RESUME_TASK Procedures.

> **See Also:**
>
> Table 127-2

Syntax

```
DBMS_PARALLEL_EXECUTE.RESUME_TASK (
   task_name                      IN  VARCHAR2,
   sql_stmt                       IN  CLOB,
   language_flag                  IN  NUMBER,
   edition                        IN  VARCHAR2  DEFAULT NULL,
   apply_crossedition_trigger     IN  VARCHAR2  DEFAULT NULL,
   fire_apply_trigger             IN  BOOLEAN   DEFAULT TRUE,
   parallel_level                 IN  NUMBER    DEFAULT 0,
   job_class                      IN  VARCHAR2  DEFAULT 'DEFAULT_JOB_CLASS',
```

```
   force                          IN  BOOLEAN   DEFAULT FALSE);

DBMS_PARALLEL_EXECUTE.RESUME_TASK (
   task_name                      IN  VARCHAR2,
   force                          IN  BOOLEAN   DEFAULT FALSE);
```

Parameters

Table 127-19 RESUME_TASK Procedure Parameters

Parameter	Description
task_name	Name of the task
sql_stmt	SQL statement; must have :start_id and :end_id placeholders
language_flag	Determines how Oracle handles the SQL statement. The following options are recognized: • V6 (or 0) specifies version 6 behavior • NATIVE (or 1) specifies normal behavior for the database to which the program is connected • V7 (or 2) specifies Oracle database version 7 behavior
edition	Specifies the edition in which to run the statement. Default is the current edition.
apply_crossedition_trigger	Specifies the unqualified name of a forward crossedition trigger that is to be applied to the specified SQL. The name is resolved using the edition and current_schema setting in which the statement is to be executed. The trigger must be owned by the user who executes the statement.
fire_apply_trigger	Indicates whether the specified apply_crossedition_trigger is itself to be executed, or only to used as be a guide in selecting other triggers
parallel_level	Number of parallel jobs; zero if run in serial; NULL uses the default parallelism
job_class	If running in parallel, the jobs all belong to the specified job class
force	If TRUE, do not raise an error if the status is PROCESSING.

Examples

Suppose the chunk table contains the following chunk ranges:

```
START_ID                        END_ID
--------------------------      --------------------------
1                               10
11                              20
21                              30
```

And the specified SQL statement is:

```
UPDATE employees
      SET salary = salary + 10
      WHERE e.employee_id  BETWEEN :start_id AND :end_id
```

This procedure executes the following statements in parallel:

```
UPDATE employees
      SET salary =.salary + 10  WHERE employee_id BETWEEN 1 and 10;
      COMMIT;
```

```
UPDATE employees
      SET salary =.salary + 10  WHERE employee_id between 11 and 20;
      COMMIT;

UPDATE employees
      SET salary =.salary + 10  WHERE employee_id between 21 and 30;
      COMMIT;
```

Related Topics

- RUN_TASK Procedure
  This procedure executes the specified statement (`sql_stmt`) on the chunks in parallel.

127.7.16 RUN_TASK Procedure

This procedure executes the specified statement (`sql_stmt`) on the chunks in parallel.

It commits after processing each chunk.

The specified statement must have two placeholders called `start_id` and `end_id`, respectively, which represent the range of the chunk to be processed. The type of each placeholder must be `ROWID` where `ROWID`-based chunking was used, or `NUMBER` where `NUMBER`-based chunking was used.

Syntax

```
DBMS_PARALLEL_EXECUTE.RUN_TASK (
   task_name                    IN  VARCHAR2,
   sql_stmt                     IN  CLOB,
   language_flag                IN  NUMBER,
   edition                      IN  VARCHAR2  DEFAULT NULL,
   apply_crossedition_trigger   IN  VARCHAR2  DEFAULT NULL,
   fire_apply_trigger           IN  BOOLEAN   DEFAULT TRUE,
   parallel_level               IN  NUMBER    DEFAULT 0,
   job_class                    IN  VARCHAR2  DEFAULT 'DEFAULT_JOB_CLASS');
```

Parameters

Table 127-20 RUN_TASK Procedure Parameters

Parameter	Description
`task_name`	Name of the task
`sql_stmt`	SQL statement; must have `:start_id` and `:end_id` placeholders
`language_flag`	Determines how Oracle handles the SQL statement. The following options are recognized: • V6 (or 0) specifies version 6 behavior • `NATIVE` (or 1) specifies normal behavior for the database to which the program is connected • V7 (or 2) specifies Oracle database version 7 behavior
`edition`	Specifies the edition in which to run the statement. Default is the current edition.

Table 127-20 (Cont.) RUN_TASK Procedure Parameters

Parameter	Description
apply_crossedition_trigger	Specifies the unqualified name of a forward crossedition trigger that is to be applied to the specified SQL. The name is resolved using the edition and current_schema setting in which the statement is to be executed. The trigger must be owned by the user executes the statement.
fire_apply_trigger	Indicates whether the specified apply_crossedition_trigger is itself to be executed, or only a guide to be used in selecting other triggers.
parallel_level	Number of parallel jobs; zero if run in serial; NULL uses the default parallelism.
job_class	If running in parallel, the jobs belong to the specified job class

Usage Notes

- The SQL statement is executed as the current user.
- Since this subprogram is subject to reexecution on error, you need to take great care in submitting a statement to RUN_TASK that is not idempotent.
- Chunks can be executed in parallel by DBMS_SCHEDULER job slaves. Therefore, parallel execution requires CREATE JOB system privilege. The job slaves is created under the current user. The default number of job slaves is computed as the product of Oracle parameters cpu_count and parallel_threads_per_cpu. On a Real Application Clusters installation, the number of job slaves is the sum of individual settings on each node in the cluster. This procedure returns only when all the chunks are processed. In parallel cases, this procedure returns only when all the job slaves finished.

Examples

Suppose the chunk table contains the following chunk ranges:

```
START_ID                            END_ID
--------------------------          --------------------------
1                                   10
11                                  20
21                                  30
```

And the specified SQL statement is:

```
UPDATE employees
      SET salary = salary + 10
      WHERE e.employee_id  BETWEEN :start_id AND :end_id
```

This procedure executes the following statements in parallel:

```
UPDATE employees
      SET salary =.salary + 10  WHERE employee_id BETWEEN 1 and 10;
      COMMIT;

UPDATE employees
      SET salary =.salary + 10  WHERE employee_id between 11 and 20;
      COMMIT;

UPDATE employees
```

```
      SET salary =.salary + 10  WHERE employee_id between 21 and 30;
      COMMIT;
```

127.7.17 SET_CHUNK_STATUS Procedure

This procedure sets the status of the chunk.

The START_TIMESTAMP and END_TIMESTAMP of the chunk is updated according to the new status:

```
Value of the new Status              Side Effect
--------------------------           --------------------------
UNASSIGNED                           START_TIMESTAMP and END_TIMESTAMP
                                     will be cleared
ASSIGNED                             START_TIMESTAMP will be the current time
                                     and END_TIMESTAMP will be cleared.
PROCESSED or PROCESSED_WITH_ERROR    The current time will be recorded
                                     in END_TIMESTAMP
```

> **See Also:**
>
> Views

Syntax

```
DBMS_PARALLEL_EXECUTE.SET_CHUNK_STATUS (
   task_name       IN VARCHAR2,
   chunk_id        OUT NUMBER,
   status          IN  NUMBER,
   err_num         IN  NUMBER   DEFAULT NULL,
   err_msg         IN  VARCHAR2 DEFAULT NULL);
```

Parameters

Table 127-21 SET_CHUNK_STATUS Procedure Parameters

Parameter	Description
task_name	Name of the task
chunk_id	Chunk_id of the chunk
status	Status of the chunk: UNASSIGNED, ASSIGNED, PROCESSED PROCESSED_WITH_ERROR
err_num	Error code returned during the processing of the chunk
err_msg	Error message returned during the processing of the chunk

127.7.18 STOP_TASK Procedure

This procedure stops the task and related job slaves.

Syntax

```
DBMS_PARALLEL_EXECUTE.STOP_TASK (
   task_name       IN VARCHAR2);
```

Parameters

Table 127-22 STOP_TASK Procedure Parameters

Parameter	Description
task_name	Name of the task

127.7.19 TASK_STATUS Procedure

This procedure returns the task status.

Syntax

```
DBMS_PARALLEL_EXECUTE.TASK_STATUS (
   task_name       IN VARCHAR2);
```

Parameters

Table 127-23 TASK_STATUS Procedure Parameters

Parameter	Description
task_name	Name of the task

128
DBMS_PART

The DBMS_PART package provides an interface for maintenance and management operations on partitioned objects.

> **See Also:**
>
> - *Oracle Database Reference* for related views

This chapter contains the following topics:

- Security Model
- Operational Notes
- Summary of DBMS_PART Subprograms

128.1 DBMS_PART Security Model

DBMS_PART is an invoker's rights package, running with the privileges of the user.

128.2 DBMS_PART Operational Notes

The following operational notes apply to DBMS_PART.

- DBMS_PART ignores all the errors that it runs into during the cleanup process.
- To display the message `PL/SQL procedure executed successfully` requires at least one cleanup operation to be successful.

128.3 Summary of DBMS_PART Subprograms

This table briefly describes the subprograms of DBMS_PART package.

Table 128-1 DBMS_PART Package Subprograms

Subprogram	Description
CLEANUP_GIDX Procedure	Gathers the list of global indexes where optimized asynchronous index maintenance has taken place to clean up entries pointing to data segments that no longer exist
CLEANUP_GIDX_JOB Procedure	
CLEANUP_ONLINE_OP Procedure	Cleans up failed online move operations

128.3.1 CLEANUP_GIDX Procedure

As a consequence of prior partition maintenance operations with asynchronous global index maintenance, global indexes can contain entries pointing to data segments that no longer exist. These stale index rows will not cause any correctness issues or corruptions during any operation on the table or index, whether these are queries, DMLs, DDLs or analyze. This procedure will identify and cleanup these global indexes to ensure efficiency in terms of storage and performance.

Syntax

```
DBMS_PART.CLEANUP_GIDX (
   schema_name_in    IN   VARCHAR2 DEFAULT NULL,
   table_name_in     IN   VARCHAR2 DEFAULT NULL,
   parallel          IN   VARCHAR2 DEFAULT NULL,
   options           IN   VARCHAR2 DEFAULT NULL);
```

Parameters

Table 128-2 CLEANUP_GIDX Function Parameters

Parameter	Description
schema_name_in	Non-NULL processes only indexes on tables in the given schema
table_name_in	Non-NULL processes only indexes on the given table in the given schema (schema_name_in must be non-NULL if table_name_in is non-NULL)
parallel	The parallel degree to use for the ALTER INDEX DDLs.
options	The following options are supported: • CLEANUP_ORPHANS: implies that 'cleanup only' mechanism is used. • COALESCE: implies that 'coalesce cleanup' mechanism is used.

128.3.2 CLEANUP_GIDX_JOB Procedure

This procedure will identify and cleanup these global indexes to ensure efficiency in terms of storage and performance.

Syntax

```
DBMS_PART.CLEANUP_GIDX_JOB (
   parallel          IN   VARCHAR2 DEFAULT NULL,
   options           IN   VARCHAR2 DEFAULT NULL);
```

Parameters

Table 128-3 CLEANUP_GIDX_JOB Function Parameters

Parameter	Description
parallel	The parallel degree to use for the ALTER INDEX DDLs.

Table 128-3 (Cont.) CLEANUP_GIDX_JOB Function Parameters

Parameter	Description
options	The following options are supported: • CLEANUP_ORPHANS: implies that 'cleanup only' mechanism is used. • COALESCE: implies that coalesce cleanup mechanism is used.

128.3.3 CLEANUP_ONLINE_OP Procedure

There are many possible points of failure when performing ALTER TABLE ... MOVE PARTITION ... ONLINE operations. This procedure pro-actively cleans up such failed online move operations instead of waiting for the background process (SMON) to do so.

Syntax

```
DBMS_PART.CLEANUP_ONLINE_OP (
   schema_name       IN   VARCHAR2 DEFAULT NULL,
   table_name        IN   VARCHAR2 DEFAULT NULL,
   partition_name    IN   VARCHAR2 DEFAULT NULL);
```

Parameters

Table 128-4 CLEANUP_ONLINE_OP Function Parameters

Parameter	Description
schema_name	Name of schema
table_name	Name of schema
partition_name	Name of partition

Usage Notes

- If schema_name, table_name and partition_name are specified, this cleans up the failed online move operation for the specified partition.
- If schema_name and table_name are specified, this cleans up all failed online move operations for all the partitions of the specified table.
- If only schema_name is specified, this cleans up all failed online move operations in the schema.
- If no arguments are provided, we cleans up all the failed online move operations in the system.
- All other cases raise ORA-20000 to inform the user of invalid inputs as arguments.

129
DBMS_PCLXUTIL

The DBMS_PCLXUTIL package provides intra-partition parallelism for creating partition-wise local indexes. DBMS_PCLXUTIL circumvents the limitation that, for local index creation, the degree of parallelism is restricted to the number of partitions as only one parallel execution server process for each partition is used.

> **See Also:**
>
> There are several rules concerning partitions and indexes. For more information, see *Oracle Database Concepts* and*Oracle Database Administrator's Guide*.

This chapter contains the following topics:

- Overview
- Security Model
- Operational Notes
- Rules and Limits
- Summary of DBMS_PCLXUTIL Subprograms

129.1 DBMS_PCLXUTIL Overview

DBMS_PCLXUTIL uses the DBMS_JOB package to provide a greater degree of parallelism for creating a local index for a partitioned table. This is achieved by asynchronous inter-partition parallelism using the background processes (with DBMS_SCHEDULER), in combination with intra-partition parallelism using the parallel execution server.

DBMS_PCLXUTIL works with both range and range-hash composite partitioning.

The DBMS_PCLXUTIL package can be used during the following DBA tasks:

1. Local index creation

   The procedure BUILD_PART_INDEX assumes that the dictionary information for the local index already exists. This can be done by issuing the create index SQL command with the UNUSABLE option.

   ```
   CREATE INDEX <idx_name> on <tab_name>(...) local(...) unusable;
   ```

   This causes the dictionary entries to be created without "building" the index itself, the time consuming part of creating an index. Now, invoking the procedure BUILD_PART_INDEX causes a concurrent build of local indexes with the specified degree of parallelism.

   ```
   EXECUTE dbms_pclxutil.build_part_index(4,4,<tab_name>,<idx_name>,FALSE);
   ```

For composite partitions, the procedure automatically builds local indexes for all subpartitions of the composite table.

2. Local index maintenance

   By marking desired partitions usable or unusable, the `BUILD_PART_INDEX` procedure also enables selective rebuilding of local indexes. The `force_opt` parameter provides a way to override this and build local indexes for all partitions.

   ```
   ALTER INDEX <idx_name> local(...) unusable;
   ```

   Rebuild only the desired (sub)partitions (that are marked unusable):

   ```
   EXECUTE dbms_pclxutil.build_part_index(4,4,<tab_name>,<idx_name>,FALSE);
   ```

   Rebuild all (sub)partitions using `force_opt = TRUE`:

   ```
   EXECUTE dbms_pclxutil.build_part_index(4,4,<tab_name>,<idx_name>,TRUE);
   ```

   A progress report is produced, and the output appears on screen when the program is ended (because the `DBMS_OUTPUT` package writes messages to a buffer first, and flushes the buffer to the screen only upon termination of the program).

129.2 DBMS_PCLXUTIL Security Model

This utility can be run only as table owner, and not as any other user.

129.3 DBMS_PCLXUTIL Operational Notes

`DBMS_PCLXUTIL` submits a job for each partition. It is the responsibility of the user/dba to control the number of concurrent jobs by setting the `INIT.ORA` parameter `JOB_QUEUE_PROCESSES` correctly. There is minimal error checking for correct syntax. Any errors are reported in the job queue process trace files.

129.4 DBMS_PCLXUTIL Rules and Limits

Because `DBMS_PCLXUTIL` uses the `DBMS_JOB` package, you must be aware of the following limitations pertaining to `DBMS_JOB`:

- You must decide appropriate values for the `job_queue_processes` initialization parameter. Clearly, if the job processes are not started before calling `BUILD_PART_INDEX`(), then the package will not function properly. The background processes are specified by the following `init.ora` parameters:

  ```
  job_queue_processes=n   #the number of background processes = n
  ```

- Failure conditions are reported only in the trace files (a `DBMS_JOB` limitation), making it impossible to give interactive feedback to the user. This package prints a failure message, removes unfinished jobs from the queue, and requests the user to take a look at the `j*.trc` trace files.

> **Note:**
>
> For range partitioning, the minimum compatibility mode is 8.0; for range-hash composite partitioning, the minimum compatibility mode is 8*i*.

129.5 Summary of DBMS_PCLXUTIL Subprograms

The `DBMS_PCLXUTIL` package has one subprogram, the `BUILD_PART_INDEX` procedure.

Table 129-1 DBMS_PCLXUTIL Package Subprograms

Subprogram	Description
BUILD_PART_INDEX Procedure	Provides intra-partition parallelism for creating partition-wise local indexes

129.5.1 BUILD_PART_INDEX Procedure

This procedure provides intra-partition parallelism for creating partition-wise local indexes.

Syntax

```
DBMS_PCLXUTIL.BUILD_PART_INDEX (
   jobs_per_batch  IN NUMBER   DEFAULT 1,
   procs_per_job   IN NUMBER   DEFAULT 1,
   tab_name        IN VARCHAR2 DEFAULT NULL,
   idx_name        IN VARCHAR2 DEFAULT NULL,
   force_opt       IN BOOLEAN  DEFAULT FALSE);
```

Parameters

Table 129-2 BUILD_PART_INDEX Procedure Parameters

Parameter	Description
`jobs_per_batch`	The number of concurrent partition-wise "local index builds".
`procs_per_job`	The number of parallel execution servers to be utilized for each local index build (1 <= `procs_per_job` <= `max_slaves`).
`tab_name`	The name of the partitioned table (an exception is raised if the table does not exist or not partitioned).
`idx_name`	The name given to the local index (an exception is raised if a local index is not created on the table `tab_name`).
`force_opt`	If `TRUE`, then force rebuild of all partitioned indexes; otherwise, rebuild only the partitions marked '`UNUSABLE`'.

Usage Notes

This utility can be run only as table owner, and not as any other user.

Examples

Suppose a table `PROJECT` is created with two partitions `PROJ001` and `PROJ002`, along with a local index `IDX`.

A call to the procedure `BUILD_PART_INDEX(2,4,'PROJECT','IDX',TRUE)` produces the following output:

```
SQLPLUS> EXECUTE dbms_pclxutil.build_part_index(2,4,'PROJECT','IDX',TRUE);
Statement processed.
INFO: Job #21 created for partition PROJ002 with 4 slaves
INFO: Job #22 created for partition PROJ001 with 4 slaves
```

130
DBMS_PDB

The DBMS_PDB package provides an interface to examine and manipulate data about pluggable databases (PDBs) in a multitenant container database (CDB). It also contains an interface specify which database objects are application common objects. You can migrate a PDB from one CDB to another CDB. After the migration is complete, all backups of the PDB before migration is available and useable in the destination CDB.

> **Note:**
>
> A multitenant container database is the only supported architecture in Oracle Database 20c. While the documentation is being revised, legacy terminology may persist. In most cases, "database" and "non-CDB" refer to a CDB or PDB, depending on context. In some contexts, such as upgrades, "non-CDB" refers to a non-CDB from a previous release.

> - *Oracle XML DB Developer's Guide* for information about configuring protocol ports and DNS mappings
> - *Oracle Database SQL Language Reference* for information about creating PDBs
> - *Oracle Database Security Guide* regarding how to create audit policies in a multitenant environment

This chapter contains the following topics:

- Overview
- Security Model
- Summary of DBMS_PDB Subprograms

130.1 DBMS_PDB Overview

A multitenant container database (CDB) is an Oracle database that includes zero, one, or many user-created pluggable databases (PDBs). The DBMS_PDB package provides an interface to examine and manipulate data about pluggable databases (PDBs). The subprograms in this package can also set a database object to one of the following types of

application common objects in an application container: data-linked object, extended data-linked object, or metadata-linked object.

A data-linked application common object stores data in the application root that can be accessed and modified by all of the application PDBs in the application container. For an extended data-linked object, each application PDB can create its own specific data while sharing the common data in the application root. Therefore, with an extended data-linked object, only the data stored in the application root is common for all application PDBs. A metadata-linked application common object stores the metadata for the specific object, such as a table, in the application root, so that the containers in the application container have the same structure for the object but different data. This package also contains a procedure that specifies that a database object is not an application common object.

Typically, the subprograms in this package are used in the following cases:

- An application that is installed in a PDB is migrated to an application container. The application can be migrated to the application root or to an application PDB. For example, you can migrate an application installed in a PDB plugged into an Oracle Database 12*c* Release 1 (12.1) CDB to an application container in an Oracle Database 12*c* Release 2 (12.2) CDB.
- An application is installed in an application root using an installation program that does not allow setting application common objects.

> **See Also:**

> *Oracle Database Administrator's Guide* for information about migrating an application to an application container

130.2 DBMS_PDB Security Model

Users must have the `EXECUTE` privilege to run the procedures of `DBMS_PDB` package.

130.3 Summary of DBMS_PDB Subprograms

This table lists and describes `DBMS_PDB` package subprograms.

> **Note:**
>
> A multitenant container database is the only supported architecture in Oracle Database 20c. While the documentation is being revised, legacy terminology may persist. In most cases, "database" and "non-CDB" refer to a CDB or PDB, depending on context. In some contexts, such as upgrades, "non-CDB" refers to a non-CDB from a previous release.

Table 130-1 DBMS_PDB Package Subprograms

Subprogram	Description
CHECK_PLUG_COMPATIBILITY Function	Uses an XML file describing a pluggable database (PDB) to determine whether it may be plugged into a given multitenant container database (CDB).
DESCRIBE Procedure	Generates an XML file describing the specified pluggable database (PDB).
EXPORTRMANBACKUP Procedure	Needs to be called only when a non-CDB is migrated as PDB. This procedure needs to be executed in non-CDB database. For PDb relocation, it is automatically called during unplugin.
RECOVER Procedure	Generates an XML file describing a pluggable database by using data files belonging to the pluggable database (PDB).
REMOVE_LINK Procedure	Specifies that a database object is not an application common object.
SET_DATA_LINKED Procedure	Sets a database object to a data-linked application common object
SET_EXT_DATA_LINKED Procedure	Sets a database object to an extended data-linked application common object.
SET_METADATA_LINKED Procedure	Sets a database object to a metadata-linked application common object.
SET_PROFILE_EXPLICIT Procedure	Sets a profile as an application common profile in an application container.
SET_ROLE_EXPLICIT Procedure	Sets a role as an application common role in an application container.
SET_USER_EXPLICIT Procedure	This procedure sets a local user as an application common user in an application container.

130.3.1 CHECK_PLUG_COMPATIBILITY Function

This function uses an XML file describing a pluggable database (PDB) to determine whether it may be plugged into a given multitenant container database (CDB).

Syntax

```
DBMS_PDB.CHECK_PLUG_COMPATIBILITY (
   pdb_descr_file    IN   VARCHAR2,
   pdb_name          IN   VARCHAR2 DEFAULT NULL)
 RETURN BOOLEAN;
```

Parameters

Table 130-2 *CHECK_PLUG_COMPATIBILITY Procedure Parameters*

Parameter	Description
pdb_descr_file	Path of the XML file that will contain description of a PDB
pdb_name	Name which will be given to the PDB represented by pdb_descr_file when plugged into a given CDB. If not specified, the name will be extracted from pdb_descr_file.

Return Values

TRUE if the PDB described by pdb_descr_file is compatible with the given CDB, FALSE otherwise. If this function returns FALSE, then query the PDB_PLUG_IN_VIOLATIONS data dictionary view to find information about the errors that are found.

> **See Also:**
>
> *Oracle Database Reference* for information about the PDB_PLUG_IN_VIOLATIONS view

130.3.2 DESCRIBE Procedure

This procedure generates an XML file describing the specified pluggable database (PDB). This file can then be passed to the CHECK_PLUG_COMPATIBILITY Function to determine if the PDB described by the XML file may be plugged into a given multitenant container database (CDB).

Syntax

```
DBMS_PDB.DESCRIBE (
   pdb_descr_file    IN   VARCHAR2,
   pdb_name          IN   VARCHAR2 DEFAULT NULL);
```

Parameters

Table 130-3 *DESCRIBE Procedure Parameters*

Parameter	Description
pdb_descr_file	Path of the XML file that will contain description of a PDB
pdb_name	Name of a PDB to be described. A remote database is specified by including @dblink.

Usage Notes

- If pdb_name is omitted, the PDB to which the session is connected will be described.
- If pdb_name is omitted, and the session is connected to the Root, an error will be returned.

Related Topics

- CHECK_PLUG_COMPATIBILITY Function
  This function uses an XML file describing a pluggable database (PDB) to determine whether it may be plugged into a given multitenant container database (CDB).

130.3.3 EXPORTRMANBACKUP Procedure

This procedure exports the RMAN backup information that belongs to a pluggable database to its dictionary before unplug so that pre-plugin backups can be used. This procedure needs to be called only for non-CDB to PDB migration. For PDB relocation, this procedure need not be called.

> **Note:**
>
> A multitenant container database is the only supported architecture in Oracle Database 20c. While the documentation is being revised, legacy terminology may persist. In most cases, "database" and "non-CDB" refer to a CDB or PDB, depending on context. In some contexts, such as upgrades, "non-CDB" refers to a non-CDB from a previous release.

Syntax

```
DBMS_PDB.EXPORTRMANBACKUP (
   pdb_name     IN VARCHAR2  DEFAULT NULL);
```

Parameters

Table 130-4 EXPORTRMANBACKUP Procedure Parameters

Parameter	Description
`pdb_name`	Name of a pluggable database whose backup information needs to be exported. Omit this parameter if you are connected to a pluggable database or a non-cdb.

Usage Notes

- The PDB must be opened in `read/write` mode.
- If the database is non-CDB, then `pdb_name` must be omitted.
- If the `pdb_name` is omitted, then the pluggable database to which the session is connected is exported.
- If the `pdb_name` is omitted and the session is connected to the `root`, an error is returned.

130.3.4 RECOVER Procedure

This procedure generates an XML file describing a pluggable database by using data files belonging to the pluggable database. This XML file can then be used to plug the pluggable database into a multitenant container database (CDB) using the `CREATE PLUGGABLE DATABASE` statement.

Use this procedure when an XML file describing a pluggable database is corrupted or lost.

Syntax

```
DBMS_PDB.RECOVER (
   pdb_descr_file    IN   VARCHAR2,
   pdb_name          IN   VARCHAR2,
   filenames         IN   VARCHAR2);
```

Parameters

Table 130-5 *RECOVER Procedure Parameters*

Parameter	Description
pdb_descr_file	Path of the XML file that contains description of a pluggable database
pdb_name	Name of a pluggable database
filenames	Comma-separated list of datafile paths and/or directories containing datafiles for the pluggable database

130.3.5 REMOVE_LINK Procedure

This procedure specifies that a database object is not an application common object. In an application container, application common objects are shared between multiple containers.

Syntax

```
DBMS_PDB.REMOVE_LINK (
   schema_name  IN VARCHAR2,
   object_name  IN VARCHAR2,
   namespace    IN NUMBER,
   edition_name IN VARCHAR2  DEFAULT NULL);
```

Parameters

Table 130-6 *REMOVE_LINK Procedure Parameters*

Parameter	Description
schema_name	The name of the schema that owns the database object.
object_name	The name of the database object.
namespace	The namespace of the database object. The NAMESPACE column of the DBA_OBJECTS view shows the namespace of an object.
edition_name	The name of the edition for the database object.

See Also:

Oracle Database Administrator's Guide for information about migrating an application to an application container

130.3.6 SET_DATA_LINKED Procedure

This procedure sets a database object to a data-linked application common object. In an application container, data-linked application common objects store data in the application root only, and the data can be accessed by all of the application PDBs in the application container. The data in a data-linked application common object can be modified only in the application root.

You can use this procedure to set data-linked application common objects when you migrate an application that is installed in a PDB to an application container. The application can be migrated to the application root or to an application PDB. For example, you can migrate an application installed in a PDB plugged into an Oracle Database 12*c* Release 1 (12.1) CDB to an application container in an Oracle Database 12*c* Release 2 (12.2) CDB.

Syntax

```
DBMS_PDB.SET_DATA_LINKED (
   schema_name  IN VARCHAR2,
   object_name  IN VARCHAR2,
   namespace    IN NUMBER,
   edition_name IN VARCHAR2  DEFAULT NULL);
```

Parameters

Table 130-7 *SET_DATA_LINKED Procedure Parameters*

Parameter	Description
`schema_name`	The name of the schema that owns the database object.
`object_name`	The name of the database object.
`namespace`	The namespace of the database object. The `NAMESPACE` column of the `DBA_OBJECTS` view shows the namespace of an object.
`edition_name`	The name of the edition for the database object.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for information about migrating an application to an application container

130.3.7 SET_EXT_DATA_LINKED Procedure

This procedure sets a database object to an extended data-linked application common object. In an application container, for an extended data-linked object, each application PDB can create its own specific data while sharing the common data in the application root. Therefore, only the data stored in the application root is common for all application PDBs.

You can use this procedure to set extended data-linked application common objects when you migrate an application that is installed in a PDB to an application container. The application can be migrated to the application root or to an application PDB. For example, you can migrate an application installed in a PDB plugged into an Oracle Database 12*c*

Release 1 (12.1) CDB to an application container in an Oracle Database 12*c* Release 2 (12.2) CDB.

Syntax

```
DBMS_PDB.SET_EXT_DATA_LINKED (
   schema_name  IN VARCHAR2,
   object_name  IN VARCHAR2,
   namespace    IN NUMBER,
   edition_name IN VARCHAR2  DEFAULT NULL);
```

Parameters

Table 130-8 *SET_EXT_DATA_LINKED Procedure Parameters*

Parameter	Description
`schema_name`	The name of the schema that owns the database object.
`object_name`	The name of the database object.
`namespace`	The namespace of the database object. The `NAMESPACE` column of the `DBA_OBJECTS` view shows the namespace of an object.
`edition_name`	The name of the edition for the database object.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for information about migrating an application to an application container

130.3.8 SET_METADATA_LINKED Procedure

This procedure sets a database object to a metadata-linked application common object. In an application container, metadata-linked application common objects store the metadata for specific objects, such as tables, so that the containers that share the application common object have the same structure but different data.

You can use this procedure to set metadata-linked application common objects when you migrate an application that is installed in a PDB to an application container. The application can be migrated to the application root or to an application PDB. For example, you can migrate an application installed in a PDB plugged into an Oracle Database 12*c* Release 1 (12.1) CDB to an application container in an Oracle Database 12*c* Release 2 (12.2) CDB.

Syntax

```
DBMS_PDB.SET_METADATA_LINKED (
   schema_name  IN VARCHAR2,
   object_name  IN VARCHAR2,
   namespace    IN NUMBER,
   edition_name IN VARCHAR2  DEFAULT NULL);
```

Parameters

Table 130-9 *SET_METADATA_LINKED Procedure Parameters*

Parameter	Description
`schema_name`	The name of the schema that owns the database object.
`object_name`	The name of the database object.
`namespace`	The namespace of the database object. The `NAMESPACE` column of the `DBA_OBJECTS` view shows the namespace of an object.
`edition_name`	The name of the edition for the database object.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for information about migrating an application to an application container

130.3.9 SET_PROFILE_EXPLICIT Procedure

This procedure sets a profile as an application common profile in an application container. This procedure is intended for migrating a profile from a previous release to an application container in the current release.

This procedure must be invoked in an application install, patch, upgrade, or uninstall operation in an application root.

Syntax

```
DBMS_PDB.SET_PROFILE_EXPLICIT (
   profile_name IN VARCHAR2);
```

Parameters

Table 130-10 *SET_PROFILE_EXPLICIT Procedure Parameters*

Parameter	Description
`profile_name`	The name of the profile.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for information about migrating an application to an application container.

130.3.10 SET_ROLE_EXPLICIT Procedure

This procedure sets a role as an application common role in an application container. This procedure is intended for migrating a role from a previous release to an application container in the current release.

This procedure must be invoked in an application install, patch, upgrade, or uninstall operation in an application root.

Syntax

```
DBMS_PDB.SET_ROLE_EXPLICIT (
   role_name IN VARCHAR2);
```

Parameters

Table 130-11 *SET_ROLE_EXPLICIT Procedure Parameters*

Parameter	Description
role_name	The name of the role.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for information about migrating an application to an application container.

130.3.11 SET_USER_EXPLICIT Procedure

This procedure sets a local user as an application common user in an application container.

This procedure must be invoked in an application install, patch, upgrade, or uninstall operation in an application root.

Syntax

```
DBMS_PDB.SET_USER_EXPLICIT (
   user_name IN VARCHAR2);
```

Parameters

Table 130-12 *SET_USER_EXPLICIT Procedure Parameters*

Parameter	Description
user_name	The name of the user.

131
DBMS_PDB_ALTER_SHARING

In an application container with a pre-installed application, the `DBMS_PDB_ALTER_SHARING` package provides an interface to set database objects as application common objects or to specify that a database object is not an application common object.

> **Note:**
>
> This package provides a subset of the subprograms in the `DBMS_PDB` package. Users who do not have `EXECUTE` privilege on the `DBMS_PDB` package can be granted `EXECUTE` privilege on this package to run these subprograms.

> **See Also:**
>
> - *Oracle Database Administrator's Guide* for information about migrating an application to an application container
> - *Oracle XML DB Developer's Guide* for information about configuring protocol ports and DNS mappings
> - *Oracle Database SQL Language Reference* for information about creating PDBs
> - *Oracle Database Security Guide* regarding how to create audit policies in a multitenant environment

This chapter contains the following topics:

- DBMS_PDB_ALTER_SHARING Overview
- DBMS_PDB_ALTER_SHARING Security Model
- Summary of DBMS_PDB_ALTER_SHARING Subprograms

131.1 DBMS_PDB_ALTER_SHARING Overview

The subprograms in this package can set a database object to one of the following types of application common objects in an application container: data-linked object, extended data-linked object, or metadata-linked object.

A data-linked application common object stores data in the application root that can be accessed and modified by all of the application PDBs in the application container. For an extended data-linked object, each application PDB can create its own specific data while sharing the common data in the application root. Therefore, with an extended data-linked object, only the data stored in the application root is common for all application PDBs. A metadata-linked application common object stores the metadata for the specific object, such as a table, in the application root, so that the containers in the application container have the

same structure for the object but different data. This package also contains a procedure that specifies that a database object is not an application common object.

You can use the subprograms in this package when you

Typically, the subprograms in this package are used in the following cases:

- An application that is installed in a PDB is migrated to an application container. The application can be migrated to the application root or to an application PDB. For example, you can migrate an application installed in a PDB plugged into an Oracle Database 12*c* Release 1 (12.1) CDB to an application container in an Oracle Database 12*c* Release 2 (12.2) CDB.
- An application is installed in an application root using an installation program that does not allow setting application common objects.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for information about migrating an application to an application container

131.2 DBMS_PDB_ALTER_SHARING Security Model

This package provides a subset of the subprograms in the `DBMS_PDB` package. User who do not have `EXECUTE` privilege on the `DBMS_PDB` package can be granted `EXECUTE` privilege on this package to run these subprograms.

Security on this package can be controlled in either of the following ways:

- Granting `EXECUTE` on this package to selected users or roles.
- Granting `EXECUTE_CATALOG_ROLE` to selected users or roles.

If subprograms in the package are run from within a stored procedure, then the user who runs the subprograms must be granted `EXECUTE` privilege on the package directly. It cannot be granted through a role.

131.3 Summary of DBMS_PDB_ALTER_SHARING Subprograms

This table lists and briefly describes `DBMS_PDB_ALTER_SHARING` package subprograms.

Table 131-1 DBMS_PDB_ALTER_SHARING Subprograms

Subprogram	Description
REMOVE_LINK Procedure	Specifies that a database object is not an application common object
SET_DATA_LINKED Procedure	Sets a database object to a data-linked application common object
SET_EXT_DATA_LINKED Procedure	Sets a database object to an extended data-linked application common object

Table 131-1 (Cont.) DBMS_PDB_ALTER_SHARING Subprograms

Subprogram	Description
SET_METADATA_LINKED Procedure	Sets a database object to a metadata-linked application common object
SET_PROFILE_EXPLICIT Procedure	Sets a profile as an application common profile in an application container.
SET_ROLE_EXPLICIT Procedure	Sets a role as an application common role in an application container.
SET_USER_EXPLICIT Procedure	Sets a local user as an application common user in an application container.

131.3.1 REMOVE_LINK Procedure

This procedure specifies that a database object is not an application common object. In an application container, application common objects are shared between multiple containers.

Syntax

```
DBMS_PDB_ALTER_SHARING.REMOVE_LINK (
   schema_name  IN VARCHAR2,
   object_name  IN VARCHAR2,
   namespace    IN NUMBER,
   edition_name IN VARCHAR2  DEFAULT NULL);
```

Parameters

Table 131-2 *REMOVE_LINK Procedure Parameters*

Parameter	Description
schema_name	The name of the schema that owns the database object.
object_name	The name of the database object.
namespace	The namespace of the database object. The NAMESPACE column of the DBA_OBJECTS view shows the namespace of an object.
edition_name	The name of the edition for the database object.

See Also:

Oracle Database Administrator's Guide for information about migrating an application to an application container

131.3.2 SET_DATA_LINKED Procedure

This procedure sets a database object to a data-linked application common object. In an application container, data-linked application common objects store data in the application root only, and the data can be accessed by all of the application PDBs in the application

container. The data in a data-linked application common object can be modified only in the application root.

You can use this procedure to set data-linked application common objects when you migrate an application that is installed in a PDB to an application container. The application can be migrated to the application root or to an application PDB. For example, you can migrate an application installed in a PDB plugged into an Oracle Database 12*c* Release 1 (12.1) CDB to an application container in an Oracle Database 12*c* Release 2 (12.2) CDB.

Syntax

```
DBMS_PDB_ALTER_SHARING.SET_DATA_LINKED (
   schema_name  IN VARCHAR2,
   object_name  IN VARCHAR2,
   namespace    IN NUMBER,
   edition_name IN VARCHAR2  DEFAULT NULL);
```

Parameters

Table 131-3 *SET_DATA_LINKED Procedure Parameters*

Parameter	Description
`schema_name`	The name of the schema that owns the database object.
`object_name`	The name of the database object.
`namespace`	The namespace of the database object. The `NAMESPACE` column of the `DBA_OBJECTS` view shows the namespace of an object.
`edition_name`	The name of the edition for the database object.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for information about migrating an application to an application container

131.3.3 SET_EXT_DATA_LINKED Procedure

This procedure sets a database object to an extended data-linked application common object. In an application container, for an extended data-linked object, each application PDB can create its own specific data while sharing the common data in the application root. Therefore, only the data stored in the application root is common for all application PDBs.

You can use this procedure to set extended data-linked application common objects when you migrate an application that is installed in a PDB to an application container. The application can be migrated to the application root or to an application PDB. For example, you can migrate an application installed in a PDB plugged into an Oracle Database 12*c* Release 1 (12.1) CDB to an application container in an Oracle Database 12*c* Release 2 (12.2) CDB.

Syntax

```
DBMS_PDB_ALTER_SHARING.SET_EXT_DATA_LINKED (
   schema_name  IN VARCHAR2,
   object_name  IN VARCHAR2,
   namespace    IN NUMBER,
   edition_name IN VARCHAR2  DEFAULT NULL);
```

Parameters

Table 131-4 *SET_EXT_DATA_LINKED Procedure Parameters*

Parameter	Description
schema_name	The name of the schema that owns the database object.
object_name	The name of the database object.
namespace	The namespace of the database object. The NAMESPACE column of the DBA_OBJECTS view shows the namespace of an object.
edition_name	The name of the edition for the database object.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for information about migrating an application to an application container

131.3.4 SET_METADATA_LINKED Procedure

This procedure sets a database object to a metadata-linked application common object. In an application container, metadata-linked application common objects store the metadata for specific objects, such as tables, so that the containers that share the application common object have the same structure but different data.

You can use this procedure to set metadata-linked application common objects when you migrate an application that is installed in a PDB to an application container. The application can be migrated to the application root or to an application PDB. For example, you can migrate an application installed in a PDB plugged into an Oracle Database 12*c* Release 1 (12.1) CDB to an application container in an Oracle Database 12*c* Release 2 (12.2) CDB.

Syntax

```
DBMS_PDB_ALTER_SHARING.SET_METADATA_LINKED (
   schema_name  IN VARCHAR2,
   object_name  IN VARCHAR2,
   namespace    IN NUMBER,
   edition_name IN VARCHAR2  DEFAULT NULL);
```

Parameters

Table 131-5 *SET_METADATA_LINKED Procedure Parameters*

Parameter	Description
`schema_name`	The name of the schema that owns the database object.
`object_name`	The name of the database object.
`namespace`	The namespace of the database object. The `NAMESPACE` column of the `DBA_OBJECTS` view shows the namespace of an object.
`edition_name`	The name of the edition for the database object.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for information about migrating an application to an application container

131.3.5 SET_PROFILE_EXPLICIT Procedure

This procedure sets a profile as an application common profile in an application container. This procedure is intended for migrating a profile from a previous release to an application container in the current release.

This procedure must be invoked in an application install, patch, upgrade, or uninstall operation in an application root.

Syntax

```
DBMS_PDB_ALTER_SHARING.SET_PROFILE_EXPLICIT (
   profile_name IN VARCHAR2);
```

Parameters

Table 131-6 *SET_PROFILE_EXPLICIT Procedure Parameters*

Parameter	Description
`profile_name`	The name of the profile.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for information about migrating an application to an application container.

131.3.6 SET_ROLE_EXPLICIT Procedure

This procedure sets a role as an application common role in an application container. This procedure is intended for migrating a role from a previous release to an application container in the current release.

This procedure must be invoked in an application install, patch, upgrade, or uninstall operation in an application root.

Syntax

```
DBMS_PDB_ALTER_SHARING.SET_ROLE_EXPLICIT (
   role_name IN VARCHAR2);
```

Parameters

Table 131-7 *SET_ROLE_EXPLICIT Procedure Parameters*

Parameter	Description
role_name	The name of the role.

> **See Also:**
>
> *Oracle Database Administrator's Guide* for information about migrating an application to an application container.

131.3.7 SET_USER_EXPLICIT Procedure

This procedure sets a local user as an application common user in an application container.

This procedure must be invoked in an application install, patch, upgrade, or uninstall operation in an application root.

Syntax

```
DBMS_PDB_ALTER_SHARING.SET_USER_EXPLICIT (
   user_name IN VARCHAR2);
```

Parameters

Table 131-8 *SET_USER_EXPLICIT Procedure Parameters*

Parameter	Description
user_name	The name of the user.

132
DBMS_PERF

The DBMS_PERF package provides and interface to generate active reports for monitoring database performance

> **See Also:**
>
> *Oracle Database PL/SQL Language Reference* for more information about "Avoiding SQL Injection in PL/SQL"

This chapter contains the following topics:

- Overview
- Security Model
- Summary of DBMS_PERF Subprograms

132.1 DBMS_PERF Overview

The DBMS_PERF package provides an interface for generating database performance reports. All subprograms return an active report and these reports can be generated at the system level, session level or at SQL level.

132.2 DBMS_PERF Security Model

The DBMS_PERF package requires the DBA role.

132.3 Summary of DBMS_PERF Subprograms

This table lists the `DBMS_PERF` subprograms and briefly describes them.

Table 132-1 DBMS_PERF Package Subprograms

Subprogram	Description
REPORT_PERFHUB Function	Generates a composite active performance report of the entire database system for a specified time period
REPORT_SESSION Function	Generates a performance report for a specific database session where a session is identified by `inst_id`, `sid`, and `serial_num`.
REPORT_SQL Function	Generates an active performance report for a particular SQL statement identified by its `sql_id`.

132.3.1 REPORT_PERFHUB Function

This function generates a composite active performance report of the entire database system for a specified time period.

Syntax

```
DBMS_PERF.REPORT_PERFHUB (
   is_realtime          IN NUMBER   DEFAULT NULL,
   outer_start_time     IN DATE     DEFAULT NULL,
   outer_end_time       IN DATE     DEFAULT NULL,
   selected_start_time  IN DATE     DEFAULT NULL,
   selected_end_time    IN DATE     DEFAULT NULL,
   inst_id              IN NUMBER   DEFAULT NULL,
   dbid                 IN NUMBER   DEFAULT NULL,
   monitor_list_detail  IN NUMBER   DEFAULT NULL,
   workload_sql_detail  IN NUMBER   DEFAULT NULL,
   addm_task_detail     IN NUMBER   DEFAULT NULL,
   report_reference     IN VARCHAR2 DEFAULT NULL,
   report_level         IN VARCHAR2 DEFAULT NULL,
   type                 IN VARCHAR2 DEFAULT 'ACTIVE',
   base_path            IN VARCHAR2 DEFAULT NULL);
 RETURN CLOB;
```

Parameters

Table 132-2 *REPORT_PERFHUB Function Parameters*

Parameter	Description
`is_realtime`	If 1, then real-time. If `NULL` (default) or `0`, then historical mode.
`outer_start_time`	Start time of outer period shown in the time selector. If `NULL` (default): • If `is_realtime=0` (historical), then 24 hours before `outer_end_time`. • If `is_realtime=1` (realtime mode), then 1 hour before `outer_end_time`.
`outer_end_time`	End time of outer period shown in the time selector. If `NULL` (default), then latest AWR snapshot. • If `is_realtime=0` (historical), then the latest AWR snapshot • If `is_realtime=1` (realtime mode), this is the current time (and any input is ignored)
`selected_start_time`	Start time period of selection. If `NULL` (default) • If `is_realtime=0`, then 1 hour before `selected_end_time` • If `is_realtime=1`, then 5 minutes before `selected_end_time`
`selected_end_time`	End time period of selection. If `NULL` (default) • If `is_realtime=0`, then latest AWR snapshot • `If is_realtime=1`, then current time

Table 132-2 (Cont.) *REPORT_PERFHUB Function Parameters*

Parameter	Description
`inst_id`	Instance ID to for which to retrieve data • If `-1`, then current instance • If number is specified, then for that instance • If `NULL` (default), then all instances
`dbid`	`DBID` to query. • If `NULL`, then current `DBID`. • If `is_realtime=1`, then `DBID` must be the local `DBID`.
`monitor_list_detail`	Top N in SQL monitor list for which to retrieve SQL monitor details. • If `NULL` (default), then retrieves top 10 • If `0`, then retrieves no monitor list details
`workload_sql_detail`	Top N in Workload Top SQL list to retrieve monitor details, • If `NULL` (default), then retrieves top 10 • If `0`, then retrieves no monitor list details
`addm_task_detail`	Maximum N latest ADDM tasks to retrieve • If `NULL` (default), retrieves available data but no more than N • If `0`, then retrieves no ADDM task details
`report_reference`	Must be `NULL` when used from SQL*Plus.
`report_level`	`'typical'` will get all tabs in performance hub
`type`	Report type: • `'ACTIVE'` (default) • `'xml'` returns XML
`base_path`	URL path for HTML resources since flex HTML requires access to external files. This is only valid for type='`ACTIVE`' and is typically not used. Default value will retrieve the required files from OTN.

Usage Notes

- Once a time period is selected, the performance information is collected and presented based on performance subject areas.
- The time period can be real-time or historical.
- When real-time data is selected, more granular data is presented because data points are available every minute.
- When historical data is selected, more detailed data (broken down by different metrics) is presented, but the data points are averaged out to the Automatic Workload Repository (AWR) interval (usually an hour).
- Different tabs are available in the Performance Hub, depending on whether is_real-time is 1 for real time mode or 0 for historical mode.

132.3.2 REPORT_SESSION Function

This function produces a performance report for a specific database session where a session is identified by `inst_id`, `sid`, and`serial_num`.

If any of those parameters are missing, then the report is for the current session.

The session-level performance report contains the following tabs:

- Summary - This tab contains key identifiers and attributes of the session along with a summary of its activity data. It also contains a list of SQLs, PLSQL blocks and Database Operations (DBOP) executed by that session that were monitored by Real-time SQL Monitoring.
- Activity - This tab shows activity broken down by wait classes for this session. The data used for this chart is fetched from Active Session History (ASH).
- Metrics - This tab shows charts for certain key metrics for the selected session over time and is only available in historical mode. Some of the metrics shown are CPU usage, PGA usage, IO Throughput and IO Requests.

Syntax

```
DBMS_PERF.REPORT_SESSION (
    inst_id              IN NUMBER   DEFAULT NULL,
    sid                  IN NUMBER   DEFAULT NULL,
    serial               IN NUMBER   DEFAULT NULL,
    is_realtime          IN NUMBER   DEFAULT NULL,
    outer_start_time     IN DATE     DEFAULT NULL,
    outer_end_time       IN DATE     DEFAULT NULL,
    selected_start_time  IN DATE     DEFAULT NULL,
    selected_end_time    IN DATE     DEFAULT NULL,
    dbid                 IN NUMBER   DEFAULT NULL,
    monitor_list_detail  IN NUMBER   DEFAULT NULL,
    report_reference     IN VARCHAR2 DEFAULT NULL,
    report_level         IN VARCHAR2 DEFAULT NULL,
    type                 IN VARCHAR2 DEFAULT 'ACTIVE',
    base_path            IN VARCHAR2 DEFAULT NULL)
  RETURN CLOB;
```

Parameters

Table 132-3 *REPORT_SESSION Function Parameters*

Parameter	Description
`inst_id`	Instance ID to for which to retrieve data. If `NULL` (default), then instance of current session.
`sid`	Session ID for which to retrieve performance. If `NULL`, uses current session.
`serial`	Serial# of session. If `NULL`, then the serial# of the specified `sid` is used provided the session is connected.
`is_realtime`	If `1`, then real-time. If `NULL` (default) or `0`, then historical mode.

Table 132-3 (Cont.) *REPORT_SESSION Function Parameters*

Parameter	Description
`outer_start_time`	Start time of outer period shown in the time selector. If `NULL` (default): • If `is_realtime=0` (historical), then 24 hours before `outer_end_time`. • If `is_realtime=1` (realtime mode), then 1 hour before `outer_end_time`.
`outer_end_time`	End time of outer period shown in the time selector. If `NULL` (default), then latest AWR snapshot. • If `is_realtime=0` (historical), then the latest AWR snapshot • If `is_realtime=1` (realtime mode), this is the current time (and any input is ignored)
`selected_start_time`	Start time period of selection. If `NULL` (default) • If `is_realtime=0`, then 1 hour before `selected_end_time` • If `is_realtime=1`, then 5 minutes before `selected_end_time`
`selected_end_time`	End time period of selection. If `NULL` (default) • If `is_realtime=0`, then latest AWR snapshot • If `is_realtime=1`, then current time
`dbid`	`DBID` to query. • If `NULL`, then current `DBID`. • If `is_realtime=1`, then `DBID` must be the local `DBID`.\
`monitor_list_detail`	Top N in SQL monitor list for which to retrieve SQL monitor details. • If `NULL` (default), then retrieves top 10 • If `0`, then retrieves no monitor list details
`report_reference`	Must be `NULL` when used from SQL*Plus.
`report_level`	`'typical'` will get all tabs in the session hub (or session details)
`type`	Report type: • `'ACTIVE'` (default) • `'xml'` returns XML
`base_path`	URL path for HTML resources since flex HTML requires access to external files

132.3.3 REPORT_SQL Function

This function generates an active performance report for a particular SQL statement identified by its `sql_id`.

The SQL-level performance report contains the following tabs:

- Summary - This tab contains an overview of the SQL statement with key attributes like the SQL text, user name, sessions executing it, and related information. It also contains a Plans tab which shows statistics and activity for each distinct plan for this SQL statement found in memory and in the AWR.

- Activity - This tab shows activity broken down by wait classes for this SQL statement. The data used for this chart is fetched from Active Session History (ASH).
- Execution Statistics - This tab shows statistics and activity for each distinct plan for this statement along with a graphical and tabular representation of the plan.
- Monitored SQL - All executions of this SQL statement that were monitored by Real-time SQL Monitoring are listed in this tab.
- Plan Control - This tab shows information about SQL Profiles and SQL Plan Baselines if they exist for this SQL statement.
- Historical Statistics - This tab is available only in Historical mode. It contains statistics, such as number of executions, number of I/Os, rows processed, and other information produced over time for different execution plans. This information is retrieved from AWR.

Syntax

```
DBMS_PERF.REPORT_SQL (
    sql_id               IN varchar2 default null,
    is_realtime          IN number   default null,
    outer_start_time     IN date     default null,
    outer_end_time       IN date     default null,
    selected_start_time  IN date     default null,
    selected_end_time    IN date     default null,
    inst_id              IN number   default null,
    dbid                 IN number   default null,
    monitor_list_detail  IN number   default null,
    report_reference     IN varchar2 default null,
    report_level         IN varchar2 default null,    type                 IN
varchar2 default 'ACTIVE',
    base_path            IN varchar2 default null);
  RETURN CLOB;
```

Parameters

Table 132-4 ***REPORT_SQL Function Parameters***

Parameter	Description
`sql_id`	`SQL_ID` for which to retrieve performance. If `NULL`, gets SQL details for the last executed SQL statement.
`is_realtime`	If `1`, then real-time. If `NULL` (default) or `0`, then historical mode.
`outer_start_time`	Start time of outer period shown in the time selector. If `NULL` (default): • If `is_realtime=0` (historical), then 24 hours before `outer_end_time`. • If `is_realtime=1` (realtime mode), then 1 hour before `outer_end_time`.
`outer_end_time`	End time of outer period shown in the time selector. If `NULL` (default), then latest AWR snapshot. • If `is_realtime=0` (historical), then the latest AWR snapshot • If `is_realtime=1` (realtime mode), this is the current time (and any input is ignored)

Table 132-4 (Cont.) *REPORT_SQL Function Parameters*

Parameter	Description
`selected_start_time`	Start time period of selection. If `NULL` (default) • If `is_realtime=0`, then 1 hour before `selected_end_time` • If `is_realtime=1`, then 5 minutes before `selected_end_time`
`selected_end_time`	End time period of selection. If `NULL` (default) • If `is_realtime=0`, then latest AWR snapshot • If `is_realtime=1`, then current time
`inst_id`	Instance ID to for which to retrieve data. If `NULL` (default), then instance of current session.
`dbid`	`DBID` to query. • If `NULL`, then current `DBID`. • If `is_realtime=1`, then `DBID` must be the local `DBID`.\
`monitor_list_detail`	Top N in SQL monitor list for which to retrieve SQL monitor details. • If `NULL` (default), then retrieves top 10 • If `0`, then retrieves no monitor list details
`report_reference`	Must be `NULL` when used from SQL*Plus.
`report_level`	`'typical'` will get all tabs in performance hub
`type`	Report type: • `'ACTIVE'` (default) • `'xml'` returns XML
`base_path`	URL path for HTML resources since flex HTML requires access to external files

133
DBMS_PIPE

The DBMS_PIPE package lets two or more sessions in the same instance communicate. Oracle pipes are similar in concept to the pipes used in UNIX, but Oracle pipes are not implemented using the operating system pipe mechanisms.

This chapter contains the following topics:

- Overview
- Security Model
- Constants
- Operational Notes
- Exceptions
- Examples
- Summary of DBMS_PIPE Subprograms

133.1 DBMS_PIPE Overview

Pipe functionality has several potential applications: external service interface, independent transactions, alerters (non-transactional), debugging, and concentrator.

- External service interface: You can communicate with user-written services that are external to the RDBMS. This can be done effectively in a shared server process, so that several instances of the service are executing simultaneously. Additionally, the services are available asynchronously. The requestor of the service does not need to block a waiting reply. The requestor can check (with or without time out) at a later time. The service can be written in any of the 3GL languages that Oracle supports.
- Independent transactions: The pipe can communicate to a separate session which can perform an operation in an independent transaction (such as logging an attempted security violation detected by a trigger).
- Alerters (non-transactional): You can post another process without requiring the waiting process to poll. If an "after-row" or "after-statement" trigger were to alert an application, then the application would treat this alert as an indication that the data probably changed. The application would then read the data to get the current value. Because this is an "after" trigger, the application would want to do a "SELECT FOR UPDATE" to make sure it read the correct data.
- Debugging: Triggers and stored procedures can send debugging information to a pipe. Another session can keep reading out of the pipe and display it on the screen or write it to a file.
- Concentrator: This is useful for multiplexing large numbers of users over a fewer number of network connections, or improving performance by concentrating several user-transactions into one DBMS transaction.

133.2 DBMS_PIPE Security Model

Security can be achieved by use of `GRANT EXECUTE` on the `DBMS_PIPE` package by creating a pipe using the `private` parameter in the `CREATE_PIPE` function and by writing cover packages that only expose particular features or pipenames to particular users or roles.

Depending upon your security requirements, you may choose to use either public pipes or private pipes, which are described in DBMS_PIPE Operational Notes.

133.3 DBMS_PIPE Constants

This is the maximum time to wait attempting to send or receive a message.

```
maxwait   constant integer := 86400000; /* 1000 days */
```

133.4 DBMS_PIPE Operational Notes

Information sent through Oracle pipes is buffered in the system global area (SGA). All information in pipes is lost when the instance is shut down.

> **WARNING:**
>
> Pipes are independent of transactions. Be careful using pipes when transaction control can be affected.

The operation of `DBMS_PIPE` is considered with regard to the following topics:

- Public Pipes
- Writing and Reading Pipes
- Private Pipes

Public Pipes

You may create a public pipe either implicitly or explicitly. For *implicit* public pipes, the pipe is automatically created when it is referenced for the first time, and it disappears when it no longer contains data. Because the pipe descriptor is stored in the SGA, there is some space usage overhead until the empty pipe is aged out of the cache.

You create an *explicit* public pipe by calling the `CREATE_PIPE` function with the `private` flag set to `FALSE`. You must deallocate explicitly-created pipes by calling the `REMOVE_PIPE` function.

The domain of a public pipe is the schema in which it was created, either explicitly or implicitly.

Reading and Writing Pipes

Each public pipe works asynchronously. Any number of schema users can write to a public pipe, as long as they have `EXECUTE` permission on the `DBMS_PIPE` package, and

they know the name of the public pipe. However, once buffered information is read by one user, it is emptied from the buffer, and is not available for other readers of the same pipe.

The sending session builds a message using one or more calls to the PACK_MESSAGE procedure. This procedure adds the message to the session's local message buffer. The information in this buffer is sent by calling the SEND_MESSAGE function, designating the pipe name to be used to send the message. When SEND_MESSAGE is called, all messages that have been stacked in the local buffer are sent.

A process that wants to receive a message calls the RECEIVE_MESSAGE function, designating the pipe name from which to receive the message. The process then calls the UNPACK_MESSAGE procedure to access each of the items in the message.

Private Pipes

You explicitly create a private pipe by calling the CREATE_PIPE function. Once created, the private pipe persists in shared memory until you explicitly deallocate it by calling the REMOVE_PIPE function. A private pipe is also deallocated when the database instance is shut down.

You cannot create a private pipe if an implicit pipe exists in memory and has the same name as the private pipe you are trying to create. In this case, CREATE_PIPE returns an error.

Access to a private pipe is restricted to:

- Sessions running under the same userid as the creator of the pipe
- Stored subprograms executing in the same userid privilege domain as the pipe creator
- Users connected as SYSDBA

An attempt by any other user to send or receive messages on the pipe, or to remove the pipe, results in an immediate error. Any attempt by another user to create a pipe with the same name also causes an error.

As with public pipes, you must first build your message using calls to PACK_MESSAGE before calling SEND_MESSAGE. Similarly, you must call RECEIVE_MESSAGE to retrieve the message before accessing the items in the message by calling UNPACK_MESSAGE.

133.5 DBMS_PIPE Exceptions

DBMS_PIPE package subprograms can return the errors listed in the following table.

Table 133-1 DBMS_PIPE Errors

Error	Description
ORA-23321:	Pipename may not be null. This can be returned by the CREATE_PIPE function, or any subprogram that takes a pipe name as a parameter.
ORA-23322:	Insufficient privilege to access pipe. This can be returned by any subprogram that references a private pipe in its parameter list.

133.6 DBMS_PIPE Examples

These examples show use of DBMS_PIPE in debugging PL/SQL, debugging Pro*C, executing system commands, and an external service interface.

Example 1: Debugging - PL/SQL

This example shows the procedure that a PL/SQL program can call to place debugging information in a pipe.

```
CREATE OR REPLACE PROCEDURE debug (msg VARCHAR2) AS
    status  NUMBER;
BEGIN
  DBMS_PIPE.PACK_MESSAGE(LENGTH(msg));
  DBMS_PIPE.PACK_MESSAGE(msg);
  status := DBMS_PIPE.SEND_MESSAGE('plsql_debug');
  IF status != 0 THEN
    raise_application_error(-20099, 'Debug error');
  END IF;
END debug;
```

Example 2: Debugging - Pro*C

The following Pro*C code receives messages from the `PLSQL_DEBUG` pipe in the previous example, and displays the messages. If the Pro*C session is run in a separate window, then it can be used to display any messages that are sent to the debug procedure from a PL/SQL program executing in a separate session.

```
#include <stdio.h>
#include <string.h>

EXEC SQL BEGIN DECLARE SECTION;
   VARCHAR username[20];
   int     status;
   int     msg_length;
   char    retval[2000];
EXEC SQL END DECLARE SECTION;

EXEC SQL INCLUDE SQLCA;

void sql_error();

main()
{

-- Prepare username:
   strcpy(username.arr, "SCOTT/TIGER");
   username.len = strlen(username.arr);

   EXEC SQL WHENEVER SQLERROR DO sql_error();
   EXEC SQL CONNECT :username;

   printf("connected\n");

-- Start an endless loop to look for and print messages on the pipe:
   FOR (;;)
   {
      EXEC SQL EXECUTE
         DECLARE
```

```
            len INTEGER;
            typ INTEGER;
            sta INTEGER;
            chr VARCHAR2(2000);
         BEGIN
            chr := '';
            sta := dbms_pipe.receive_message('plsql_debug');
            IF sta = 0 THEN
               DBMS_PIPE.UNPACK_MESSAGE(len);
               DBMS_PIPE.UNPACK_MESSAGE(chr);
            END IF;
            :status := sta;
            :retval := chr;
            IF len IS NOT NULL THEN
               :msg_length := len;
            ELSE
               :msg_length := 2000;
            END IF;
         END;
      END-EXEC;
      IF (status == 0)
         printf("\n%.*s\n", msg_length, retval);
      ELSE
         printf("abnormal status, value is %d\n", status);
   }
}

void sql_error()
{
   char msg[1024];
   int rlen, len;
   len = sizeof(msg);
   sqlglm(msg, &len, &rlen);
   printf("ORACLE ERROR\n");
   printf("%.*s\n", rlen, msg);
   exit(1);
}
```

Example 3: Execute System Commands

This example shows PL/SQL and Pro*C code let a PL/SQL stored procedure (or anonymous block) call PL/SQL procedures to send commands over a pipe to a Pro*C program that is listening for them.

The Pro*C program sleeps and waits for a message to arrive on the named pipe. When a message arrives, the Pro*C program processes it, carrying out the required action, such as executing a UNIX command through the *system*() call or executing a SQL command using embedded SQL.

`DAEMON.SQL` is the source code for the PL/SQL package. This package contains procedures that use the `DBMS_PIPE` package to send and receive message to and from the Pro*C daemon. Note that full handshaking is used. The daemon always sends a message back to the package (except in the case of the `STOP` command). This is valuable, because it allows the PL/SQL procedures to be sure that the Pro*C daemon is running.

You can call the DAEMON packaged procedures from an anonymous PL/SQL block using SQL*Plus or Enterprise Manager. For example:

```
SQLPLUS> variable rv number
SQLPLUS> execute :rv := DAEMON.EXECUTE_SYSTEM('ls -la');
```

On a UNIX system, this causes the Pro*C daemon to execute the command *system*("*ls -la*").

Remember that the daemon needs to be running first. You might want to run it in the background, or in another window beside the SQL*Plus or Enterprise Manager session from which you call it.

The DAEMON.SQL also uses the DBMS_OUTPUT package to display the results. For this example to work, you must have execute privileges on this package.

DAEMON.SQL Example. This is the code for the PL/SQL DAEMON package:

```
CREATE OR REPLACE PACKAGE daemon AS
  FUNCTION execute_sql(command VARCHAR2,
                       timeout NUMBER DEFAULT 10)
    RETURN NUMBER;

  FUNCTION execute_system(command VARCHAR2,
                          timeout NUMBER DEFAULT 10)
    RETURN NUMBER;

  PROCEDURE stop(timeout NUMBER DEFAULT 10);
END daemon;
/
CREATE OR REPLACE PACKAGE BODY daemon AS

  FUNCTION execute_system(command VARCHAR2,
                          timeout NUMBER DEFAULT 10)
  RETURN NUMBER IS

    status       NUMBER;
    result       VARCHAR2(20);
    command_code NUMBER;
    pipe_name    VARCHAR2(30);
  BEGIN
    pipe_name := DBMS_PIPE.UNIQUE_SESSION_NAME;

    DBMS_PIPE.PACK_MESSAGE('SYSTEM');
    DBMS_PIPE.PACK_MESSAGE(pipe_name);
    DBMS_PIPE.PACK_MESSAGE(command);
    status := DBMS_PIPE.SEND_MESSAGE('daemon', timeout);
    IF status <> 0 THEN
      RAISE_APPLICATION_ERROR(-20010,
        'Execute_system: Error while sending.  Status = ' ||
         status);
    END IF;

    status := DBMS_PIPE.RECEIVE_MESSAGE(pipe_name, timeout);
    IF status <> 0 THEN
      RAISE_APPLICATION_ERROR(-20011,
        'Execute_system: Error while receiving.
         Status = ' || status);
    END IF;

    DBMS_PIPE.UNPACK_MESSAGE(result);
    IF result <> 'done' THEN
      RAISE_APPLICATION_ERROR(-20012,
        'Execute_system: Done not received.');
    END IF;

    DBMS_PIPE.UNPACK_MESSAGE(command_code);
```

```
    DBMS_OUTPUT.PUT_LINE('System command executed.  result = ' ||
                         command_code);
    RETURN command_code;
  END execute_system;

  FUNCTION execute_sql(command VARCHAR2,
                       timeout NUMBER DEFAULT 10)
  RETURN NUMBER IS

    status       NUMBER;
    result       VARCHAR2(20);
    command_code NUMBER;
    pipe_name    VARCHAR2(30);

  BEGIN
    pipe_name := DBMS_PIPE.UNIQUE_SESSION_NAME;

    DBMS_PIPE.PACK_MESSAGE('SQL');
    DBMS_PIPE.PACK_MESSAGE(pipe_name);
    DBMS_PIPE.PACK_MESSAGE(command);
    status := DBMS_PIPE.SEND_MESSAGE('daemon', timeout);
    IF status <> 0 THEN
      RAISE_APPLICATION_ERROR(-20020,
        'Execute_sql: Error while sending.  Status = ' || status);
    END IF;

    status := DBMS_PIPE.RECEIVE_MESSAGE(pipe_name, timeout);

    IF status <> 0 THEN
      RAISE_APPLICATION_ERROR(-20021,
        'execute_sql: Error while receiving.
         Status = ' || status);
    END IF;

    DBMS_PIPE.UNPACK_MESSAGE(result);
    IF result <> 'done' THEN
      RAISE_APPLICATION_ERROR(-20022,
        'execute_sql: done not received.');
    END IF;

    DBMS_PIPE.UNPACK_MESSAGE(command_code);
    DBMS_OUTPUT.PUT_LINE
        ('SQL command executed.  sqlcode = ' || command_code);
    RETURN command_code;
  END execute_sql;

  PROCEDURE stop(timeout NUMBER DEFAULT 10) IS
    status NUMBER;
  BEGIN
    DBMS_PIPE.PACK_MESSAGE('STOP');
    status := DBMS_PIPE.SEND_MESSAGE('daemon', timeout);
    IF status <> 0 THEN
      RAISE_APPLICATION_ERROR(-20030,
        'stop: error while sending.  status = ' || status);
    END IF;
  END stop;
END daemon;
```

daemon.pc Example. This is the code for the Pro*C daemon. You must precompile this using the Pro*C Precompiler, Version 1.5.x or later. You must also specify the `USERID` and `SQLCHECK` options, as the example contains embedded PL/SQL code.

> **Note:**
>
> To use a VARCHAR output host variable in a PL/SQL block, you must initialize the length component before entering the block.

```
proc iname=daemon userid=scott/tiger sqlcheck=semantics
```

Then C-compile and link in the normal way.

```
#include <stdio.h>
#include <string.h>

EXEC SQL INCLUDE SQLCA;

EXEC SQL BEGIN DECLARE SECTION;
  char *uid = "scott/tiger";
  int status;
  VARCHAR command[20];
  VARCHAR value[2000];
  VARCHAR return_name[30];
EXEC SQL END DECLARE SECTION;

void
connect_error()
{
  char msg_buffer[512];
  int msg_length;
  int buffer_size = 512;

  EXEC SQL WHENEVER SQLERROR CONTINUE;
  sqlglm(msg_buffer, &buffer_size, &msg_length);
  printf("Daemon error while connecting:\n");
  printf("%.*s\n", msg_length, msg_buffer);
  printf("Daemon quitting.\n");
  exit(1);
}

void
sql_error()
{
  char msg_buffer[512];
  int msg_length;
  int buffer_size = 512;

  EXEC SQL WHENEVER SQLERROR CONTINUE;
  sqlglm(msg_buffer, &buffer_size, &msg_length);
  printf("Daemon error while executing:\n");
  printf("%.*s\n", msg_length, msg_buffer);
  printf("Daemon continuing.\n");
}
main()
{
command.len = 20; /*initialize length components*/
value.len = 2000;
return_name.len  = 30;
  EXEC SQL WHENEVER SQLERROR DO connect_error();
  EXEC SQL CONNECT :uid;
  printf("Daemon connected.\n");
```

```
EXEC SQL WHENEVER SQLERROR DO sql_error();
printf("Daemon waiting...\n");
while (1) {
  EXEC SQL EXECUTE
    BEGIN
      :status := DBMS_PIPE.RECEIVE_MESSAGE('daemon');
      IF :status = 0 THEN
        DBMS_PIPE.UNPACK_MESSAGE(:command);
      END IF;
    END;
  END-EXEC;
  IF (status == 0)
  {
    command.arr[command.len] = '\0';
    IF (!strcmp((char *) command.arr, "STOP"))
    {
      printf("Daemon exiting.\n");
      break;
    }

    ELSE IF (!strcmp((char *) command.arr, "SYSTEM"))
    {
      EXEC SQL EXECUTE
        BEGIN
          DBMS_PIPE.UNPACK_MESSAGE(:return_name);
          DBMS_PIPE.UNPACK_MESSAGE(:value);
        END;
      END-EXEC;
      value.arr[value.len] = '\0';
      printf("Will execute system command '%s'\n", value.arr);

      status = system(value.arr);
      EXEC SQL EXECUTE
        BEGIN
          DBMS_PIPE.PACK_MESSAGE('done');
          DBMS_PIPE.PACK_MESSAGE(:status);
          :status := DBMS_PIPE.SEND_MESSAGE(:return_name);
        END;
      END-EXEC;

      IF (status)
      {
        printf
         ("Daemon error while responding to system command.");
        printf("  status: %d\n", status);
      }
    }
    ELSE IF (!strcmp((char *) command.arr, "SQL")) {
      EXEC SQL EXECUTE
        BEGIN
          DBMS_PIPE.UNPACK_MESSAGE(:return_name);
          DBMS_PIPE.UNPACK_MESSAGE(:value);
        END;
      END-EXEC;
      value.arr[value.len] = '\0';
      printf("Will execute sql command '%s'\n", value.arr);

      EXEC SQL WHENEVER SQLERROR CONTINUE;
      EXEC SQL EXECUTE IMMEDIATE :value;
      status = sqlca.sqlcode;
```

```
      EXEC SQL WHENEVER SQLERROR DO sql_error();
      EXEC SQL EXECUTE
        BEGIN
          DBMS_PIPE.PACK_MESSAGE('done');
          DBMS_PIPE.PACK_MESSAGE(:status);
          :status := DBMS_PIPE.SEND_MESSAGE(:return_name);
        END;
      END-EXEC;

      IF (status)
      {
        printf("Daemon error while responding to sql command.");
        printf("  status: %d\n", status);
      }
    }
    ELSE
    {
      printf
        ("Daemon error: invalid command '%s' received.\n",
          command.arr);
    }
  }
  ELSE
  {
    printf("Daemon error while waiting for signal.");
    printf("  status = %d\n", status);
  }
}
EXEC SQL COMMIT WORK RELEASE;
exit(0);
```

Example 4: External Service Interface

Put the user-written 3GL code into an OCI or Precompiler program. The program connects to the database and executes PL/SQL code to read its request from the pipe, computes the result, and then executes PL/SQL code to send the result on a pipe back to the requestor.

Below is an example of a stock service request. The recommended sequence for the arguments to pass on the pipe for all service requests is:

```
protocol_version      VARCHAR2        - '1', 10 bytes or less
returnpipe            VARCHAR2        - 30 bytes or less
service               VARCHAR2        - 30 bytes or less
arg1                  VARCHAR2/NUMBER/DATE
   ...
argn                  VARCHAR2/NUMBER/DATE
```

The recommended format for returning the result is:

```
success               VARCHAR2        - 'SUCCESS' if OK,
                                        otherwise error message
arg1                  VARCHAR2/NUMBER/DATE
   ...
argn                  VARCHAR2/NUMBER/DATE
```

The "stock price request server" would do, using OCI or PRO* (in pseudo-code):

```
<loop forever>
  BEGIN dbms_stock_server.get_request(:stocksymbol); END;
```

```
  <figure out price based on stocksymbol (probably from some radio
        signal), set error if can't find such a stock>
  BEGIN dbms_stock_server.return_price(:error, :price); END;
```

A client would do:

```
BEGIN :price := stock_request('YOURCOMPANY'); end;
```

The stored procedure, `dbms_stock_server`, which is called by the preceding "stock price request server" is:

```
CREATE OR REPLACE PACKAGE dbms_stock_server IS
  PROCEDURE get_request(symbol OUT VARCHAR2);
  PROCEDURE return_price(errormsg IN VARCHAR2, price IN VARCHAR2);
END;

CREATE OR REPLACE PACKAGE BODY dbms_stock_server IS
  returnpipe    VARCHAR2(30);

  PROCEDURE returnerror(reason VARCHAR2) IS
    s INTEGER;
  BEGIN
    dbms_pipe.pack_message(reason);
    s := dbms_pipe.send_message(returnpipe);
    IF s <> 0 THEN
      raise_application_error(-20000, 'Error:' || to_char(s) ||
        ' sending on pipe');
    END IF;
  END;

  PROCEDURE get_request(symbol OUT VARCHAR2) IS
    protocol_version VARCHAR2(10);
    s                INTEGER;
    service          VARCHAR2(30);
  BEGIN
    s := dbms_pipe.receive_message('stock_service');
    IF s <> 0 THEN
      raise_application_error(-20000, 'Error:' || to_char(s) ||
        'reading pipe');
    END IF;
    dbms_pipe.unpack_message(protocol_version);
    IF protocol_version <> '1' THEN
      raise_application_error(-20000, 'Bad protocol: ' ||
        protocol_version);
    END IF;
    dbms_pipe.unpack_message(returnpipe);
    dbms_pipe.unpack_message(service);
    IF service != 'getprice' THEN
      returnerror('Service ' || service || ' not supported');
    END IF;
    dbms_pipe.unpack_message(symbol);
  END;

  PROCEDURE return_price(errormsg in VARCHAR2, price in VARCHAR2) IS
    s INTEGER;
  BEGIN
    IF errormsg is NULL THEN
      dbms_pipe.pack_message('SUCCESS');
      dbms_pipe.pack_message(price);
    ELSE
      dbms_pipe.pack_message(errormsg);
```

```
    END IF;
    s := dbms_pipe.send_message(returnpipe);
    IF s <> 0 THEN
      raise_application_error(-20000, 'Error:'||to_char(s)||
        ' sending on pipe');
    END IF;
  END;
END;
```

The procedure called by the client is:

```
CREATE OR REPLACE FUNCTION stock_request (symbol VARCHAR2)
    RETURN VARCHAR2 IS
  s        INTEGER;
  price    VARCHAR2(20);
  errormsg VARCHAR2(512);
BEGIN
  dbms_pipe.pack_message('1');  -- protocol version
  dbms_pipe.pack_message(dbms_pipe.unique_session_name); -- return pipe
  dbms_pipe.pack_message('getprice');
  dbms_pipe.pack_message(symbol);
  s := dbms_pipe.send_message('stock_service');
  IF s <> 0 THEN
    raise_application_error(-20000, 'Error:'||to_char(s)||
      ' sending on pipe');
  END IF;
  s := dbms_pipe.receive_message(dbms_pipe.unique_session_name);
  IF s <> 0 THEN
    raise_application_error(-20000, 'Error:'||to_char(s)||
      ' receiving on pipe');
  END IF;
  dbms_pipe.unpack_message(errormsg);
  IF errormsg <> 'SUCCESS' THEN
    raise_application_error(-20000, errormsg);
  END IF;
  dbms_pipe.unpack_message(price);
  RETURN price;
END;
```

You would typically only `GRANT EXECUTE` on `DBMS_STOCK_SERVICE` to the stock service application server, and would only `GRANT EXECUTE` on `stock_request` to those users allowed to use the service.

133.7 Summary of DBMS_PIPE Subprograms

This table lists the `DBMS_PIPE` subprograms and briefly describes them.

Table 133-2 DBMS_PIPE Package Subprograms

Subprogram	Description
CREATE_PIPE Function	Creates a pipe (necessary for private pipes)
NEXT_ITEM_TYPE Function	Returns datatype of next item in buffer
PACK_MESSAGE Procedures	Builds message in local buffer
PURGE Procedure	Purges contents of named pipe
RECEIVE_MESSAGE Function	Copies message from named pipe into local buffer
REMOVE_PIPE Function	Removes the named pipe
RESET_BUFFER Procedure	Purges contents of local buffer
SEND_MESSAGE Function	Sends message on named pipe: This implicitly creates a public pipe if the named pipe does not exist
UNIQUE_SESSION_NAME Function	Returns unique session name
UNPACK_MESSAGE Procedures	Accesses next item in buffer

133.7.1 CREATE_PIPE Function

This function explicitly creates a public or private pipe. If the `private` flag is `TRUE`, then the pipe creator is assigned as the owner of the private pipe.

Explicitly-created pipes can only be removed by calling `REMOVE_PIPE`, or by shutting down the instance.

Syntax

```
DBMS_PIPE.CREATE_PIPE (
   pipename     IN VARCHAR2,
   maxpipesize  IN INTEGER DEFAULT 8192,
   private      IN BOOLEAN DEFAULT TRUE)
RETURN INTEGER;
```

Pragmas

```
pragma restrict_references(create_pipe,WNDS,RNDS);
```

Parameters

Table 133-3 CREATE_PIPE Function Parameters

Parameter	Description
`pipename`	Name of the pipe you are creating. You must use this name when you call `SEND_MESSAGE` and `RECEIVE_MESSAGE`. This name must be unique across the instance. Caution: Do not use pipe names beginning with `ORA$`. These are reserved for use by procedures provided by Oracle. Pipename should not be longer than 128 bytes, and is case insensitive. At this time, the name cannot contain Globalization Support characters.

Table 133-3 (Cont.) CREATE_PIPE Function Parameters

Parameter	Description
maxpipesize	The maximum size allowed for the pipe, in bytes. The total size of all of the messages on the pipe cannot exceed this amount. The message is blocked if it exceeds this maximum. The default maxpipesize is 8192 bytes. The maxpipesize for a pipe becomes a part of the characteristics of the pipe and persists for the life of the pipe. Callers of SEND_MESSAGE with larger values cause the maxpipesize to be increased. Callers with a smaller value use the existing, larger value.
private	Uses the default, TRUE, to create a private pipe. Public pipes can be implicitly created when you call SEND_MESSAGE.

Return Values

Table 133-4 CREATE_PIPE Function Return Values

Return	Description
0	Successful. If the pipe already exists and the user attempting to create it is authorized to use it, then Oracle returns 0, indicating success, and any data already in the pipe remains. If a user connected as SYSDBA/SYSOPER re-creates a pipe, then Oracle returns status 0, but the ownership of the pipe remains unchanged.
ORA-23322	Failure due to naming conflict. If a pipe with the same name exists and was created by a different user, then Oracle signals error ORA-23322, indicating the naming conflict.

Exceptions

Table 133-5 CREATE_PIPE Function Exception

Exception	Description
Null pipe name	Permission error: Pipe with the same name already exists, and you are not allowed to use it.

133.7.2 NEXT_ITEM_TYPE Function

This function determines the datatype of the next item in the local message buffer.

After you have called RECEIVE_MESSAGE to place pipe information in a local buffer, call NEXT_ITEM_TYPE.

Syntax

```
DBMS_PIPE.NEXT_ITEM_TYPE
  RETURN INTEGER;
```

Pragmas

```
pragma restrict_references(next_item_type,WNDS,RNDS);
```

Return Values

Table 133-6 NEXT_ITEM_TYPE Function Return Values

Return	Description
0	No more items
6	NUMBER
9	VARCHAR2
11	ROWID
12	DATE
23	RAW

133.7.3 PACK_MESSAGE Procedures

This procedure builds your message in the local message buffer.

To send a message, first make one or more calls to PACK_MESSAGE. Then, call SEND_MESSAGE to send the message in the local buffer on the named pipe.

The procedure is overloaded to accept items of type VARCHAR2, NCHAR, NUMBER, DATE., RAW and ROWID items. In addition to the data bytes, each item in the buffer requires one byte to indicate its type, and two bytes to store its length. One additional byte is needed to terminate the message.The overhead for all types other than VARCHAR is 4 bytes.

Syntax

```
DBMS_PIPE.PACK_MESSAGE (
   item  IN  VARCHAR2);

DBMS_PIPE.PACK_MESSAGE (
   item  IN  NCHAR);

DBMS_PIPE.PACK_MESSAGE (
   item  IN  NUMBER);

DBMS_PIPE.PACK_MESSAGE (
   item  IN  DATE);

DBMS_PIPE.PACK_MESSAGE_RAW (
   item  IN  RAW);

DBMS_PIPE.PACK_MESSAGE_ROWID (
   item  IN  ROWID);
```

Pragmas

```
pragma restrict_references(pack_message,WNDS,RNDS);
pragma restrict_references(pack_message_raw,WNDS,RNDS);
pragma restrict_references(pack_message_rowid,WNDS,RNDS);
```

Parameters

Table 133-7 PACK_MESSAGE Procedure Parameters

Parameter	Description
item	Item to pack into the local message buffer.

Usage Notes

In Oracle database version 8.x, the char-set-id (2 bytes) and the char-set-form (1 byte) are stored with each data item. Therefore, the overhead when using Oracle database version 8.x is 7 bytes.

When you call SEND_MESSAGE to send this message, you must indicate the name of the pipe on which you want to send the message. If this pipe already exists, then you must have sufficient privileges to access this pipe. If the pipe does not already exist, then it is created automatically.

Exceptions

ORA-06558 is raised if the message buffer overflows (currently 4096 bytes). Each item in the buffer takes one byte for the type, two bytes for the length, plus the actual data. There is also one byte needed to terminate the message.

133.7.4 PURGE Procedure

This procedure empties the contents of the named pipe.

An empty implicitly-created pipe is aged out of the shared global area according to the least-recently-used algorithm. Thus, calling PURGE lets you free the memory associated with an implicitly-created pipe.

Syntax

```
DBMS_PIPE.PURGE (
   pipename  IN  VARCHAR2);
```

Pragmas

```
pragma restrict_references(purge,WNDS,RNDS);
```

Parameters

Table 133-8 PURGE Procedure Parameters

Parameter	Description
pipename	Name of pipe from which to remove all messages. The local buffer may be overwritten with messages as they are discarded. Pipename should not be longer than 128 bytes, and is case-insensitive.

Usage Notes

Because PURGE calls RECEIVE_MESSAGE, the local buffer might be overwritten with messages as they are purged from the pipe. Also, you can receive an ORA-23322 (insufficient privileges) error if you attempt to purge a pipe with which you have insufficient access rights.

Exceptions

Permission error if pipe belongs to another user.

133.7.5 RECEIVE_MESSAGE Function

This function copies the message into the local message buffer.

Syntax

```
DBMS_PIPE.RECEIVE_MESSAGE (
   pipename     IN VARCHAR2,
   timeout      IN INTEGER      DEFAULT maxwait)
RETURN INTEGER;
```

Pragmas

```
pragma restrict_references(receive_message,WNDS,RNDS);
```

Parameters

Table 133-9 RECEIVE_MESSAGE Function Parameters

Parameter	Description
pipename	Name of the pipe on which you want to receive a message. Names beginning with ORA$ are reserved for use by Oracle
timeout	Time to wait for a message, in seconds. The default value is the constant MAXWAIT, which is defined as 86400000 (1000 days). A timeout of 0 lets you read without blocking.

Return Values

Table 133-10 RECEIVE_MESSAGE Function Return Values

Return	Description
0	Success
1	Timed out. If the pipe was implicitly-created and is empty, then it is removed.
2	Record in the pipe is too large for the buffer. (This should not happen.)
3	An interrupt occurred.
ORA-23322	User has insufficient privileges to read from the pipe.

Usage Notes

To receive a message from a pipe, first call RECEIVE_MESSAGE. When you receive a message, it is removed from the pipe; hence, a message can only be received once. For implicitly-created pipes, the pipe is removed after the last record is removed from the pipe.

If the pipe that you specify when you call RECEIVE_MESSAGE does not already exist, then Oracle implicitly creates the pipe and waits to receive the message. If the message does not arrive within a designated timeout interval, then the call returns and the pipe is removed.

After receiving the message, you must make one or more calls to UNPACK_MESSAGE to access the individual items in the message. The UNPACK_MESSAGE procedure is overloaded to unpack items of type DATE, NUMBER, VARCHAR2, and there are two additional procedures to unpack RAW and ROWID items. If you do not know the type of data that you are attempting to unpack, then call NEXT_ITEM_TYPE to determine the type of the next item in the buffer.

Exceptions

Table 133-11 RECEIVE_MESSAGE Function Exceptions

Exception	Description
Null pipe name	Permission error. Insufficient privilege to remove the record from the pipe. The pipe is owned by someone else.

133.7.6 RESET_BUFFER Procedure

This procedure resets the PACK_MESSAGE and UNPACK_MESSAGE positioning indicators to 0.

Because all pipes share a single buffer, you may find it useful to reset the buffer before using a new pipe. This ensures that the first time you attempt to send a message to your pipe, you do not inadvertently send an expired message remaining in the buffer.

Syntax

```
DBMS_PIPE.RESET_BUFFER;
```

Pragmas

```
pragma restrict_references(reset_buffer,WNDS,RNDS);
```

133.7.7 REMOVE_PIPE Function

This function removes explicitly-created pipes.

Pipes created implicitly by SEND_MESSAGE are automatically removed when empty. However, pipes created explicitly by CREATE_PIPE are removed only by calling REMOVE_PIPE, or by shutting down the instance. All unconsumed records in the pipe are removed before the pipe is deleted.

This is similar to calling PURGE on an implicitly-created pipe.

Syntax

```
DBMS_PIPE.REMOVE_PIPE (
   pipename  IN  VARCHAR2)
RETURN INTEGER;
```

Pragmas

```
pragma restrict_references(remove_pipe,WNDS,RNDS);
```

Parameters

Table 133-12 REMOVE_PIPE Function Parameters

Parameter	Description
pipename	Name of pipe that you want to remove.

Return Values

Table 133-13 REMOVE_PIPE Function Return Values

Return	Description
0	Success If the pipe does not exist, or if the pipe already exists and the user attempting to remove it is authorized to do so, then Oracle returns 0, indicating success, and any data remaining in the pipe is removed.
ORA-23322	Insufficient privileges. If the pipe exists, but the user is not authorized to access the pipe, then Oracle signals error ORA-23322, indicating insufficient privileges.

Exceptions

Table 133-14 REMOVE_PIPE Function Exception

Exception	Description
Null pipe name	Permission error: Insufficient privilege to remove pipe. The pipe was created and is owned by someone else.

133.7.8 SEND_MESSAGE Function

This function sends a message on the named pipe.

The message is contained in the local message buffer, which was filled with calls to PACK_MESSAGE. You can create a pipe explicitly using CREATE_PIPE, otherwise, it is created implicitly.

Syntax

```
DBMS_PIPE.SEND_MESSAGE (
    pipename     IN VARCHAR2,
    timeout      IN INTEGER DEFAULT MAXWAIT,
```

```
   maxpipesize  IN INTEGER DEFAULT 8192)
 RETURN INTEGER;
```

Pragmas

```
pragma restrict_references(send_message,WNDS,RNDS);
```

Parameters

Table 133-15 SEND_MESSAGE Function Parameters

Parameter	Description
pipename	Name of the pipe on which you want to place the message. If you are using an explicit pipe, then this is the name that you specified when you called CREATE_PIPE. Caution: Do not use pipe names beginning with '0RA$'. These names are reserved for use by procedures provided by Oracle. Pipename should not be longer than 128 bytes, and is case-insensitive. At this time, the name cannot contain Globalization Support characters.
timeout	Time to wait while attempting to place a message on a pipe, in seconds. The default value is the constant MAXWAIT, which is defined as 86400000 (1000 days).
maxpipesize	Maximum size allowed for the pipe, in bytes. The total size of all the messages on the pipe cannot exceed this amount. The message is blocked if it exceeds this maximum. The default is 8192 bytes. The maxpipesize for a pipe becomes a part of the characteristics of the pipe and persists for the life of the pipe. Callers of SEND_MESSAGE with larger values cause the maxpipesize to be increased. Callers with a smaller value simply use the existing, larger value. Specifying maxpipesize as part of the SEND_MESSAGE procedure eliminates the need for a separate call to open the pipe. If you created the pipe explicitly, then you can use the optional maxpipesize parameter to override the creation pipe size specifications.

Return Values

Table 133-16 SEND_MESSAGE Function Return Values

Return	Description
0	Success. If the pipe already exists and the user attempting to create it is authorized to use it, then Oracle returns 0, indicating success, and any data already in the pipe remains. If a user connected as SYSDBS/SYSOPER re-creates a pipe, then Oracle returns status 0, but the ownership of the pipe remains unchanged.

Table 133-16 (Cont.) SEND_MESSAGE Function Return Values

Return	Description
1	Timed out. This procedure can timeout either because it cannot get a lock on the pipe, or because the pipe remains too full to be used. If the pipe was implicitly-created and is empty, then it is removed.
3	An interrupt occurred. If the pipe was implicitly created and is empty, then it is removed.
ORA-23322	Insufficient privileges. If a pipe with the same name exists and was created by a different user, then Oracle signals error ORA-23322, indicating the naming conflict.

Exceptions

Table 133-17 SEND_MESSAGE Function Exception

Exception	Description
Null pipe name	Permission error. Insufficient privilege to write to the pipe. The pipe is private and owned by someone else.

133.7.9 UNIQUE_SESSION_NAME Function

This function receives a name that is unique among all of the sessions that are currently connected to a database.

Multiple calls to this function from the same session always return the same value. You might find it useful to use this function to supply the PIPENAME parameter for your SEND_MESSAGE and RECEIVE_MESSAGE calls.

Syntax

```
DBMS_PIPE.UNIQUE_SESSION_NAME
  RETURN VARCHAR2;
```

Pragmas

```
pragma restrict_references(unique_session_name,WNDS,RNDS,WNPS);
```

Return Values

This function returns a unique name. The returned name can be up to 30 bytes.

133.7.10 UNPACK_MESSAGE Procedures

This procedure retrieves items from the buffer.

After you have called RECEIVE_MESSAGE to place pipe information in a local buffer, call UNPACK_MESSAGE.

> **Note:**
>
> The UNPACK_MESSAGE procedure is overloaded to return items of type VARCHAR2, NCHAR, NUMBER, or DATE. There are two additional procedures to unpack RAW and ROWID items.

Syntax

```
DBMS_PIPE.UNPACK_MESSAGE (
   item  OUT VARCHAR2);

DBMS_PIPE.UNPACK_MESSAGE (
   item  OUT NCHAR);

DBMS_PIPE.UNPACK_MESSAGE (
   item  OUT NUMBER);

DBMS_PIPE.UNPACK_MESSAGE (
   item  OUT DATE);

DBMS_PIPE.UNPACK_MESSAGE_RAW (
   item  OUT RAW);

DBMS_PIPE.UNPACK_MESSAGE_ROWID (
   item  OUT ROWID);
```

Pragmas

```
pragma restrict_references(unpack_message,WNDS,RNDS);
pragma restrict_references(unpack_message_raw,WNDS,RNDS);
pragma restrict_references(unpack_message_rowid,WNDS,RNDS);
```

Parameters

Table 133-18 UNPACK_MESSAGE Procedure Parameters

Parameter	Description
item	Argument to receive the next unpacked item from the local message buffer.

Exceptions

ORA-06556 or 06559 are generated if the buffer contains no more items, or if the item is not of the same type as that requested.

134
DBMS_PLSQL_CODE_COVERAGE

The DBMS_PLSQL_CODE_COVERAGE package provides an interface for the collection of code coverage data of PL/SQL applications at the basic block level.

This chapter contains the following topics:

- DBMS_PLSQL_CODE_COVERAGE Overview
- DBMS_PLSQL_CODE_COVERAGE Security Model
- DBMS_PLSQL_CODE_COVERAGE Data Structures
- Summary of DBMS_PLSQL_CODE_COVERAGE Subprograms

134.1 DBMS_PLSQL_CODE_COVERAGE Overview

The DBMS_PLSQL_CODE_COVERAGE package provides an interface for collecting code coverage information at the basic block level of PL/SQL applications. A basic block refers to a single entry single exit block of PL/SQL code. PL/SQL developers want to know how well their test infrastructure exercised their code. The coverage tables are created using the CREATE_COVERAGE_TABLES procedure.

A typical code coverage run in a session involves calls to :

- START_COVERAGE
- Run PL/SQL code
- STOP_COVERAGE

The GET_BLOCK_MAP function helps you calculate your total coverage.

See Also:

- *Oracle Database Development Guide* for more information about using PL/SQL basic block coverage to maintain quality
- *Oracle Database PL/SQL Language Reference* for the COVERAGE PRAGMA syntax and semantics
- *Oracle Database PL/SQL Language Reference* for more information about the PLSQL_OPTIMIZE_LEVEL compilation parameter

134.2 DBMS_PLSQL_CODE_COVERAGE Security Model

The user must have `EXECUTE` privilege on the DBMS_PLSQL_CODE_COVERAGE package.

The user must have `CREATE` privilege on the unit to collect coverage information about this unit.

Coverage information is not collected for wrapped units.

134.3 DBMS_PLSQL_CODE_COVERAGE Constants

The `DBMS_PLSQL_CODE_COVERAGE` package provides constants that are used with the `namespace` parameter of the `GET_BLOCK_MAP` function.

These constants are described in the following table.

Table 134-1 DBMS_PLSQL_CODE_COVERAGE Constants

Name	Type	Value	Description
`function_namespace`	`NUMBER`	`1`	Specifies the function namespace
`package_spec_namespace`	`NUMBER`	`1`	Specifies the package specification namespace
`package_body_namespace`	`NUMBER`	`2`	Specifies the package definition (body) namespace
`procedure_namespace`	`NUMBER`	`1`	Specifies the procedure namespace
`trigger_namespace`	`NUMBER`	`3`	Specifies the trigger namespace
`type_spec_namespace`	`NUMBER`	`1`	Specifies the type specification namespace
`type_body_namespace`	`NUMBER`	`2`	Specifies the type definition (body) namespace

134.4 DBMS_PLSQL_CODE_COVERAGE Data Structures

Record Types

- MAP_REC Record Type

Table Types

- T_MAP_REC Table Type

134.4.1 MAP_REC Record Type

The MAP_REC record type defines the PL/SQL basic block location in the source code.

Syntax

```
TYPE map_rec IS RECORD (
    procedure_name VARCHAR2(32767),
    block_num      NUMBER,
    line           NUMBER,
    col            NUMBER,
    not_feasible   NUMBER);
```

Fields

Table 134-2 MAP_REC Fields

Field	Description
`procedure_name`	The name of the procedure containing the basic block
`block_num`	Identifies the basic block
`line`	Starting line of the basic block
`col`	Starting column of the basic block
`not_feasible`	Not_feasible marking of the basic block

134.4.2 T_MAP_REC Table Type

The T_MAP_REC table type specifies the collection of PL/SQL basic blocks in a unit.

Syntax

```
TYPE t_map_rec IS TABLE OF map_rec;
```

134.5 Summary of DBMS_PLSQL_CODE_COVERAGE Subprograms

This table lists the `DBMS_PLSQL_CODE_COVERAGE` subprograms and briefly describes them.

Table 134-3 DBMS_PLSQL_CODE_COVERAGE Package Subprograms

Subprogram	Description
CREATE_COVERAGE_TABLES Procedure	Creates coverage tables
GET_BLOCK_MAP Function	Gets the mapping of basic blocks to PL/SQL source
START_COVERAGE Function	Starts the coverage data collection in the user's session and returns the RUN_ID
STOP_COVERAGE Procedure	Ends the current coverage run

134.5.1 CREATE_COVERAGE_TABLES Procedure

This procedure creates the tables used for coverage data collection.

Syntax

```
DBMS_PLSQL_CODE_COVERAGE.CREATE_COVERAGE_TABLES (
   FORCE_IT     IN BOOLEAN DEFAULT FALSE);
```

Parameters

Parameter	Description
FORCE_IT	The default is to raise an error if the coverage tables already exists. If set to TRUE, the tables are dropped silently if the tables already exist, and new tables are created.

Exceptions

Table 134-4 CREATE_COVERAGE_TABLES Exceptions

Exception	Description
COVERAGE_ERROR	The FORCE_IT parameter is FALSE and the tables already exist.

134.5.2 GET_BLOCK_MAP Function

This function gets the mapping of basic blocks to PL/SQL source.

Syntax

```
DBMS_PLSQL_CODE_COVERAGE.GET_BLOCK_MAP(
                      unit_owner IN VARCHAR2,
                      unit_name  IN VARCHAR2,
                      namespace  IN POSITIVE)
  RETURN T_MAP_REC;
```

Table 134-5 Parameters

Parameter	Description
unit_owner	The owner of the unit. The unit owner is case insensitive. If the unit_owner is empty or NULL, then it defaults to the current schema.
unit_name	The unit whose mapping is to be gotten. The unit_name is case insensitive.
namespace	Namespace to which this unit_name gets resolved. See DBMS_PLSQL_CODE_COVERAGE Constants for a list of valid namespace values.

134.5.3 START_COVERAGE Function

This function starts the coverage data collection in the user's session and returns a unique identifier `RUN_ID` for the run.

Syntax

```
DBMS_PLSQL_CODE_COVERAGE.START_COVERAGE (
   run_comment   IN VARCHAR2)
   RETURN NUMBER;
```

Parameters

Parameter	Description
`run_comment`	Allows the user to name a run and identify the test.

134.5.4 STOP_COVERAGE Procedure

This procedure ends the current coverage run.

Syntax

```
DBMS_PLSQL_CODE_COVERAGE.STOP_COVERAGE;
```

Exceptions

Table 134-6 STOP_COVERAGE Exceptions

Exception	Description
`COVERAGE_ERROR`	An error is raised if the coverage tables do not exist.

135
DBMS_PREDICTIVE_ANALYTICS

Machine learning can discover useful information buried in vast amounts of data. However, both the programming interfaces and the machine learning expertise required to obtain these results are too complex for use by the wide audiences that can obtain benefits from using Oracle Machine Learning for SQL.

The `DBMS_PREDICTIVE_ANALYTICS` package addresses both of these complexities by automating the entire machine learning process from data preprocessing through model building to scoring new data. This package provides an important tool that makes machine learning possible for a broad audience of users, in particular, business analysts.

This chapter contains the following topics:

- Overview
- Security Model
- Summary of DBMS_PREDICTIVE_ANALYTICS Subprograms

135.1 DBMS_PREDICTIVE_ANALYTICS Overview

DBMS_PREDICTIVE_ANALYTICS automates parts of the machine learning process.

Machine learning, according to a commonly used process model, requires the following steps:

1. Understand the business problem.
2. Understand the data.
3. Prepare the data for mining.
4. Create models using the prepared data.
5. Evaluate the models.
6. Deploy and use the model to score new data.

`DBMS_PREDICTIVE_ANALYTICS` automates parts of step 3 — 5 of this process.

Predictive analytics procedures analyze and prepare the input data, create and test machine learning models using the input data, and then use the input data for scoring. The results of scoring are returned to the user. The models and supporting objects are not preserved after the operation completes.

135.2 DBMS_PREDICTIVE_ANALYTICS Security Model

The `DBMS_PREDICTIVE_ANALYTICS` package is owned by user `SYS` and is installed as part of database installation. Execution privilege on the package is granted to public. The routines in the package are run with invokers' rights (run with the privileges of the current user).

The `DBMS_PREDICTIVE_ANALYTICS` package exposes APIs which are leveraged by the Oracle Machine Learning for SQL option. Users who wish to invoke procedures in this package

require the `CREATE MINING MODEL` system privilege (as well as the `CREATE TABLE` and `CREATE VIEW` system privilege).

135.3 Summary of DBMS_PREDICTIVE_ANALYTICS Subprograms

This table lists and briefly describes the `DBMS_PREDICTIVE_ANALYTICS` package subprograms.

Table 135-1 DBMS_PREDICTIVE_ANALYTICS Package Subprograms

Subprogram	Purpose
EXPLAIN Procedure	Ranks attributes in order of influence in explaining a target column.
PREDICT Procedure	Predicts the value of a target column based on values in the input data.
PROFILE Procedure	Generates rules that identify the records that have the same target value.

135.3.1 EXPLAIN Procedure

The `EXPLAIN` procedure identifies the attributes that are important in explaining the variation in values of a target column.

The input data must contain some records where the target value is known (not `NULL`). These records are used by the procedure to train a model that calculates the attribute importance.

> **Note:**
>
> `EXPLAIN` supports `DATE` and `TIMESTAMP` datatypes in addition to the numeric, character, and nested datatypes supported by Oracle Machine Learning for SQL models.
>
> Data requirements for Oracle Machine Learning for SQL are described in *Oracle Machine Learning for SQL User's Guide*

The `EXPLAIN` procedure creates a result table that lists the attributes in order of their explanatory power. The result table is described in the Usage Notes.

Syntax

```
DBMS_PREDICTIVE_ANALYTICS.EXPLAIN (
     data_table_name     IN VARCHAR2,
     explain_column_name IN VARCHAR2,
     result_table_name   IN VARCHAR2,
     data_schema_name    IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 135-2 EXPLAIN Procedure Parameters

Parameter	Description
data_table_name	Name of input table or view
explain_column_name	Name of the column to be explained
result_table_name	Name of the table where results are saved
data_schema_name	Name of the schema where the input table or view resides and where the result table is created. Default: the current schema.

Usage Notes

The EXPLAIN procedure creates a result table with the columns described in Table 135-3.

Table 135-3 EXPLAIN Procedure Result Table

Column Name	Datatype	Description
ATTRIBUTE_NAME	VARCHAR2(30)	Name of a column in the input data; all columns except the explained column are listed in the result table.
EXPLANATORY_VALUE	NUMBER	Value indicating how useful the column is for determining the value of the explained column. Higher values indicate greater explanatory power. Value can range from 0 to 1. An individual column's explanatory value is independent of other columns in the input table. The values are based on how strong each individual column correlates with the explained column. The value is affected by the number of records in the input table, and the relations of the values of the column to the values of the explain column. An explanatory power value of 0 implies there is no useful correlation between the column's values and the explain column's values. An explanatory power of 1 implies perfect correlation; such columns should be eliminated from consideration for PREDICT. In practice, an explanatory power equal to 1 is rarely returned.
RANK	NUMBER	Ranking of explanatory power. Rows with equal values for explanatory_value have the same rank. Rank values are not skipped in the event of ties.

Example

The following example performs an EXPLAIN operation on the SUPPLEMENTARY_DEMOGRAPHICS table of Sales History.

```
--Perform EXPLAIN operation
BEGIN
    DBMS_PREDICTIVE_ANALYTICS.EXPLAIN(
        data_table_name      => 'supplementary_demographics',
        explain_column_name  => 'home_theater_package',
        result_table_name    => 'demographics_explain_result');
END;
/
--Display results
SELECT * FROM demographics_explain_result;
```

```
ATTRIBUTE_NAME                          EXPLANATORY_VALUE       RANK
--------------------------------------- ----------------- ----------
Y_BOX_GAMES                                   .524311073          1
YRS_RESIDENCE                                 .495987246          2
HOUSEHOLD_SIZE                                .146208506          3
AFFINITY_CARD                                  .0598227          4
EDUCATION                                     .018462703          5
OCCUPATION                                    .009721543          6
FLAT_PANEL_MONITOR                             .00013733          7
PRINTER_SUPPLIES                                       0          8
OS_DOC_SET_KANJI                                       0          8
BULK_PACK_DISKETTES                                    0          8
BOOKKEEPING_APPLICATION                                0          8
COMMENTS                                               0          8
CUST_ID                                                0          8
```

The results show that `Y_BOX_GAMES`, `YRS_RESIDENCE`, and `HOUSEHOLD_SIZE` are the best predictors of `HOME_THEATER_PACKAGE`.

135.3.2 PREDICT Procedure

The `PREDICT` procedure predicts the values of a target column.

The input data must contain some records where the target value is known (not `NULL`). These records are used by the procedure to train and test a model that makes the predictions.

> **Note:**
>
> `PREDICT` supports `DATE` and `TIMESTAMP` datatypes in addition to the numeric, character, and nested datatypes supported by Oracle Machine Learning for SQL models.
>
> Data requirements for OML4SQL are described in *Oracle Machine Learning for SQL User's Guide*

The `PREDICT` procedure creates a result table that contains a predicted target value for every record. The result table is described in the Usage Notes.

Syntax

```
DBMS_PREDICTIVE_ANALYTICS.PREDICT (
    accuracy                OUT NUMBER,
    data_table_name         IN VARCHAR2,
    case_id_column_name     IN VARCHAR2,
    target_column_name      IN VARCHAR2,
    result_table_name       IN VARCHAR2,
    data_schema_name        IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 135-4 PREDICT Procedure Parameters

Parameter	Description
accuracy	Output parameter that returns the predictive confidence, a measure of the accuracy of the predicted values. The predictive confidence for a categorical target is the most common target value; the predictive confidence for a numerical target is the mean.
data_table_name	Name of the input table or view.
case_id_column_name	Name of the column that uniquely identifies each case (record) in the input data.
target_column_name	Name of the column to predict.
result_table_name	Name of the table where results will be saved.
data_schema_name	Name of the schema where the input table or view resides and where the result table is created. Default: the current schema.

Usage Notes

The PREDICT procedure creates a result table with the columns described in Table 135-5.

Table 135-5 PREDICT Procedure Result Table

Column Name	Datatype	Description
Case ID column name	VARCHAR2 or NUMBER	The name of the case ID column in the input data.
PREDICTION	VARCHAR2 or NUMBER	The predicted value of the target column for the given case.
PROBABILITY	NUMBER	For classification (categorical target), the probability of the prediction. For regression problems (numerical target), this column contains NULL.

> **Note:**
>
> Make sure that the name of the case ID column is not 'PREDICTION' or 'PROBABILITY'.

Predictions are returned for all cases whether or not they contained target values in the input.

Predicted values for known cases may be interesting in some situations. For example, you could perform deviation analysis to compare predicted values and actual values.

Example

The following example performs a PREDICT operation and displays the first 10 predictions. The results show an accuracy of 79% in predicting whether each customer has an affinity card.

```
--Perform PREDICT operation
DECLARE
    v_accuracy NUMBER(10,9);
BEGIN
    DBMS_PREDICTIVE_ANALYTICS.PREDICT(
        accuracy             => v_accuracy,
        data_table_name      => 'supplementary_demographics',
        case_id_column_name  => 'cust_id',
        target_column_name   => 'affinity_card',
        result_table_name    => 'pa_demographics_predict_result');
    DBMS_OUTPUT.PUT_LINE('Accuracy = ' || v_accuracy);
END;
/

Accuracy = .788696903

--Display results
SELECT * FROM pa_demographics_predict_result WHERE rownum < 10;

   CUST_ID PREDICTION PROBABILITY
---------- ---------- -----------
    101501          1  .834069848
    101502          0  .991269965
    101503          0   .99978311
    101504          1  .971643388
    101505          1  .541754127
    101506          0  .803719133
    101507          0  .999999303
    101508          0  .999999987
    101509          0  .999953074
```

135.3.3 PROFILE Procedure

The PROFILE procedure generates rules that describe the cases (records) from the input data.

For example, if a target column CHURN has values 'Yes' and 'No', PROFILE generates a set of rules describing the expected outcomes. Each profile includes a rule, record count, and a score distribution.

The input data must contain some cases where the target value is known (not NULL). These cases are used by the procedure to build a model that calculates the rules.

> **Note:**
>
> PROFILE does not support nested types or dates.
>
> Data requirements for Oracle Machine Learning for SQL are described in *Oracle Machine Learning for SQL User's Guide*

The PROFILE procedure creates a result table that specifies rules (profiles) and their corresponding target values. The result table is described in the Usage Notes.

Syntax

```
DBMS_PREDICTIVE_ANALYTICS.PROFILE (
     data_table_name           IN VARCHAR2,
     target_column_name        IN VARCHAR2,
     result_table_name         IN VARCHAR2,
     data_schema_name          IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 135-6 PROFILE Procedure Parameters

Parameter	Description
data_table_name	Name of the table containing the data to be analyzed.
target_column_name	Name of the target column.
result_table_name	Name of the table where the results will be saved.
data_schema_name	Name of the schema where the input table or view resides and where the result table is created. Default: the current schema.

Usage Notes

The PROFILE procedure creates a result table with the columns described in Table 135-7.

Table 135-7 PROFILE Procedure Result Table

Column Name	Datatype	Description
PROFILE_ID	NUMBER	A unique identifier for this profile (rule).
RECORD_COUNT	NUMBER	The number of records described by the profile.
DESCRIPTION	SYS.XMLTYPE	The profile rule. See "XML Schema for Profile Rules".

XML Schema for Profile Rules

The DESCRIPTION column of the result table contains XML that conforms to the following XSD:

```
<xs:element name="SimpleRule">
  <xs:complexType>
    <xs:sequence>
      <xs:group ref="PREDICATE"/>
      <xs:element ref="ScoreDistribution" minOccurs="0" maxOccurs="unbounded"/>
    </xs:sequence>
    <xs:attribute name="id" type="xs:string" use="optional"/>
    <xs:attribute name="score" type="xs:string" use="required"/>
    <xs:attribute name="recordCount" type="NUMBER" use="optional"/>
  </xs:complexType>
</xs:element>
```

Example

This example generates a rule describing customers who are likely to use an affinity card (target value is 1) and a set of rules describing customers who are not likely to use an affinity card (target value is 0). The rules are based on only two predictors: education and occupation.

```
SET serveroutput ON
SET trimspool ON
SET pages 10000
SET long 10000
SET pagesize 10000
SET linesize 150
CREATE VIEW cust_edu_occ_view AS
             SELECT cust_id, education, occupation, affinity_card
             FROM sh.supplementary_demographics;
BEGIN
    DBMS_PREDICTIVE_ANALYTICS.PROFILE(
         DATA_TABLE_NAME    => 'cust_edu_occ_view',
         TARGET_COLUMN_NAME => 'affinity_card',
         RESULT_TABLE_NAME  => 'profile_result');
END;
/
```

This example generates eight rules in the result table `profile_result`. Seven of the rules suggest a target value of 0; one rule suggests a target value of 1. The `score` attribute on a rule identifies the target value.

This `SELECT` statement returns all the rules in the result table.

```
SELECT a.profile_id, a.record_count, a.description.getstringval()
 FROM profile_result a;
```

This `SELECT` statement returns the rules for a target value of 0.

```
SELECT *
  FROM profile_result t
  WHERE extractvalue(t.description, '/SimpleRule/@score') = 0;
```

The eight rules generated by this example are displayed as follows.

```
<SimpleRule id="1" score="0" recordCount="443">
  <CompoundPredicate booleanOperator="and">
    <SimpleSetPredicate field="OCCUPATION" booleanOperator="isIn">
      <Array type="string">"Armed-F" "Exec." "Prof." "Protec."
      </Array>

136
DBMS_PREPROCESSOR

The DBMS_PREPROCESSOR package provides an interface to print or retrieve the source text of a PL/SQL unit in its post-processed form.

This package contains the following topics:

- Overview
- Operating Notes
- Data Structures
- Summary of DBMS_PREPROCESSOR Subprograms

136.1 DBMS_PREPROCESSOR Overview

It is necessary to first understand the three styles of subprograms, in order to understand how `DBMS_PREPROCESSOR` works.

The following are the three styles of subprograms:

1. Subprograms that take a schema name, a unit type name, and the unit name.
2. Subprograms that take a `VARCHAR2` string which contains the source text of an arbitrary PL/SQL compilation unit.
3. Subprograms that take a `VARCHAR2` index-by table which contains the segmented source text of an arbitrary PL/SQL compilation unit.

Subprograms of the first style are used to print or retrieve the post-processed source text of a stored PL/SQL unit. The user must have the privileges necessary to view the original source text of this unit. The user must also specify the schema in which the unit is defined, the type of the unit, and the name of the unit. If the schema is null, then the current user schema is used. If the status of the stored unit is `VALID` and the user has the required privilege, then the post-processed source text is guaranteed to be the same as that of the unit the last time it was compiled.

Subprograms of the second or third style are used to generate post-processed source text in the current user schema. The source text is passed in as a single `VARCHAR2` string in the second style, or as a `VARCHAR2` index-by table in the third style. The source text can represent an arbitrary PL/SQL compilation unit. A typical usage is to pass the source text of an anonymous block and generate its post-processed source text in the current user schema. The third style can be useful when the source text exceeds the `VARCHAR2` length limit.

136.2 DBMS_PREPROCESSOR Operating Notes

These notes explain how DBMS_PREPROCESSOR works with the three subprogram styles.

- For subprograms of the first style, the status of the stored PL/SQL unit does not need to be `VALID`. Likewise, the source text passed in as a `VARCHAR2` string or a `VARCHAR2` index-by table may contain compile time errors. If errors are found when generating the post-processed source, the error message text will also appear at the end of the post-

processed source text. In some cases, the preprocessing can be aborted because of errors. When this happens, the post-processed source text will appear to be incomplete and the associated error message can help to indicate that an error has occurred during preprocessing.

- For subprograms of the second or third style, the source text can represent any arbitrary PL/SQL compilation unit. However, the source text of a valid PL/SQL compilation unit cannot include commonly used prefixes such as `CREATE OR REPLACE`. In general, the input source should be syntactically prepared in a way as if it were obtained from the `ALL_SOURCE` view. The following list gives some examples of valid initial syntax for some PL/SQL compilation units.

```
anonymous block   (BEGIN | DECLARE) ...
package           PACKAGE <name> ...
package body      PACKAGE BODY <name> ...
procedure         PROCEDURE <name> ...
function          FUNCTION <name> ...
type              TYPE <name> ...
type body         TYPE BODY <name> ...
trigger           (BEGIN | DECLARE) ...
```

  If the source text represents a named PL/SQL unit that is valid, that unit will not be created after its post-processed source text is generated.

- If the text of a wrapped PL/SQL unit is obtained from the `ALL_SOURCE` view, the keyword `WRAPPED` always immediately follows the name of the unit, as in this example:

```
PROCEDURE "some proc" WRAPPED
a000000
b2
...
```

  If such source text is presented to one of the GET_POST_PROCESSED_SOURCE Functions or to one of the PRINT_POST_PROCESSED_SOURCE Procedures, the exception `DBMS_PREPROCESSOR.WRAPPED_INPUT` is raised.

136.3 DBMS_PREPROCESSOR Data Structures

The `DBMS_PREPROCESSOR` package defines a `TABLE` type.

Table Types

SOURCE_LINES_T Table Type

136.3.1 DBMS_PREPROCESSOR SOURCE_LINES_T Table Type

This table type stores lines of post-processed source text. It is used to hold PL/SQL source text both before and after it is processed. It is especially useful in cases in which the amount of text exceeds 32K.

Syntax

```
TYPE source_lines_t IS
    TABLE OF VARCHAR2(32767) INDEX BY BINARY_INTEGER;
```

136.4 Summary of DBMS_PREPROCESSOR Subprograms

This table lists the DBMS_PREPROCESSOR subprograms and briefly describes them.

Table 136-1 DBMS_PREPROCESSOR Package Subprograms

Subprogram	Description
GET_POST_PROCESSED_SOURCE Functions	Returns the post-processed source text
PRINT_POST_PROCESSED_SOURCE Procedures	Prints post-processed source text

136.4.1 GET_POST_PROCESSED_SOURCE Functions

This overloaded function returns the post-processed source text. The different functionality of each form of syntax is presented along with the definition.

Syntax

Returns post-processed source text of a stored PL/SQL unit:

```
DBMS_PREPROCESSOR.GET_POST_PROCESSED_SOURCE (
   object_type    IN VARCHAR2,
   schema_name    IN VARCHAR2,
   object_name    IN VARCHAR2)
  RETURN source_lines_t;
```

Returns post-processed source text of a compilation unit:

```
DBMS_PREPROCESSOR.GET_POST_PROCESSED_SOURCE (
   source        IN VARCHAR2)
  RETURN source_lines_t;
```

Returns post-processed source text of an INDEX-BY table containing the source text of the compilation unit:

```
DBMS_PREPROCESSOR.GET_POST_PROCESSED_SOURCE (
   source        IN source_lines_t)
  RETURN source_lines_t;
```

Parameters

Table 136-2 GET_POST_PROCESSED_SOURCE Function Parameters

Parameter	Description
object_type	Must be one of PACKAGE, PACKAGE BODY, PROCEDURE, FUNCTION, TYPE, TYPE, BODY or TRIGGER. Case sensitive.
schema_name	The schema name. Case insensitive unless a quoted identifier is used. If NULL, use current schema.
object_name	The name of the object.The object_type is always case insensitive. Case insensitive unless a quoted identifier is used.
source	The source text of the compilation unit

Table 136-2 (Cont.) GET_POST_PROCESSED_SOURCE Function Parameters

Parameter	Description
source_lines_t	INDEX-BY table containing the source text of the compilation unit. The source text is a concatenation of all the non-NULL INDEX-BY table elements in ascending index order.

Return Values

The function returns an INDEX-BY table containing the lines of the post-processed source text starting from index 1.

Usage Notes

- Newline characters are not removed.
- Each line in the post-processed source text is mapped to a row in the INDEX-BY table.
- In the post-processed source, unselected text will have blank lines.

Exceptions

Table 136-3 GET_POST_PROCESSED_SOURCE Function Exceptions

Exception	Description
ORA-24234	Insufficient privileges or object does not exist
ORA-24235	Bad value for object type. Should be one of PACKAGE, PACKAGE BODY, PROCEDURE, FUNCTION, TYPE, TYPE, BODY or TRIGGER.
ORA-24236	The source text is empty
ORA-00931	Missing identifier. The object_name should not be NULL.
ORA-06502	Numeric or value error: • Character string buffer too small • A line is too long (> 32767 bytes)

136.4.2 PRINT_POST_PROCESSED_SOURCE Procedures

This overloaded procedure calls DBMS_OUTPUT.PUT_LINE to let you view post-processed source text. The different functionality of each form of syntax is presented along with the definition.

Syntax

Prints post-processed source text of a stored PL/SQL unit:

```
DBMS_PREPROCESSOR.PRINT_POST_PROCESSED_SOURCE (
   object_type    IN VARCHAR2,
   schema_name    IN VARCHAR2,
   object_name    IN VARCHAR2);
```

Prints post-processed source text of a compilation unit:

```
DBMS_PREPROCESSOR.PRINT_POST_PROCESSED_SOURCE (
   source        IN VARCHAR2);
```

Prints post-processed source text of an INDEX-BY table containing the source text of the compilation unit:

```
DBMS_PREPROCESSOR.PRINT_POST_PROCESSED_SOURCE (
   source        IN source_lines_t);
```

Parameters

Table 136-4 PRINT_POST_PROCESSED_SOURCE Procedure Parameters

Parameter	Description
object_type	Must be one of PACKAGE, PACKAGE BODY, PROCEDURE, FUNCTION, TYPE, TYPE, BODY or TRIGGER. Case sensitive.
schema_name	The schema name. Case insensitive unless a quoted identifier is used. If NULL, use current schema.
object_name	The name of the object.The object_type is always case insensitive. Case insensitive unless a quoted identifier is used.
source	The source text of the compilation unit
source_lines_t	INDEX-BY table containing the source text of the compilation unit. The source text is a concatenation of all the non-NULL INDEX-BY table elements in ascending index order.

Exceptions

Table 136-5 PRINT_POST_PROCESSED_SOURCE Procedure Exceptions

Exception	Description
ORA-24234	Insufficient privileges or object does not exist
ORA-24235	Bad value for object type. Should be one of PACKAGE, PACKAGE BODY, PROCEDURE, FUNCTION, TYPE, TYPE, BODY or TRIGGER.
ORA-24236	The source text is empty
ORA-00931	Missing identifier. The object_name should not be NULL.
ORA-06502	Numeric or value error: • Character string buffer too small • A line is too long (> 32767 bytes)

Usage Notes

The index-by table may contain holes. NULL elements are ignored when doing the concatenation.

137
DBMS_PRIVILEGE_CAPTURE

The DBMS_PRIVILEGE_CAPTURE package provides an interface to database privilege analysis.

> **See Also:**
>
> Oracle® Database Security Guide regarding on how to analyze the use of privilege grants

This chapter contains the following topics:

- Overview
- Security Model
- Constants
- Examples
- Summary of DBMS_PRIVILEGE_CAPTURE Subprograms

137.1 DBMS_PRIVILEGE_CAPTURE Overview

Database privilege analysis enables you to create a policy that records the usage of system and object privileges that have been granted to users. You then can determine the privileges that your users are using and not using. From there, you can revoke any unused privileges, thereby reducing the number of excess privilege grants for users.

By analyzing the privileges that users must have to perform specific tasks, privilege analysis policies help you to achieve a least privilege model for your users.

137.2 DBMS_PRIVILEGE_CAPTURE Security Model

The privilege analysis administrator role, CAPTURE_ADMIN, is granted EXECUTE permission on the DBMS_PRIVILEGE_CAPTURE package by default.

The CAPTURE_ADMIN role is granted to the DBA role during database installation.

137.3 DBMS_PRIVILEGE_CAPTURE Constants

The DBMS_PRIVILEGE_CAPTURE package defines several enumerated constants for specifying parameter values.

Table 137-1 DBMS_PRIVILEGE_CAPTURE Constants

Constant	Value	Type	Description
G_DATABASE	1	NUMBER	Analyzes all privilege use, except privileges used by the SYS user.
G_ROLE	2	NUMBER	Analyzes privilege use for the specified roles.
G_CONTEXT	3	NUMBER	Analyzes privilege use when the `condition` parameter evaluates to `true`.
G_ROLE_AND_CONTEXT	4	NUMBER	Analyzes privilege use for the specified roles when the `condition` parameter evaluates to true.

137.4 DBMS_PRIVILEGE_CAPTURE Examples

These examples illustrate using the `DBMS_PRIVILEGE_CAPTURE.CREATE_CAPTURE` procedure to create various types of privilege analysis, like database analysis, role analysis, and context-specific analysis. The examples also illustrate combining different conditions in context-specific analysis.

```
--Create a database privilege analysis policy
BEGIN
DBMS_PRIVILEGE_CAPTURE.CREATE_CAPTURE(
        name         => 'all_priv_analysis_pol',
        description  => 'database-wide policy to analyze all privileges',
        type         => DBMS_PRIVILEGE_CAPTURE.G_DATABASE);
END;

--Create a privilege analysis policy to analyze privileges from the role PUBLIC
BEGIN
DBMS_PRIVILEGE_CAPTURE.CREATE_CAPTURE(
       name         => 'pub_analysis_pol',
       description  => 'Policy to record privilege use by PUBLIC',
       type         => DBMS_PRIVILEGE_CAPTURE.G_ROLE,
       roles        => role_name_list('PUBLIC'));
END;

-- Create a policy to analyze privileges from the application module, "Account
-- Payable"
BEGIN
DBMS_PRIVILEGE_CAPTURE.CREATE_CAPTURE(
  name         => 'acc_pay_analysis_pol',
  type         => DBMS_PRIVILEGE_CAPTURE.G_CONTEXT,
  condition    => 'SYS_CONTEXT(''USERENV'', ''MODULE'') = ''Account Payable''');
END;

-- Create a policy that records privileges for session user APPS when running the
-- application module "Account Payable"
BEGIN
DBMS_PRIVILEGE_CAPTURE.CREATE_CAPTURE(
  name         => 'acc_pay_analysis_pol',
  type         => DBMS_PRIVILEGE_CAPTURE.G_CONTEXT,
  condition    => 'SYS_CONTEXT(''USERENV'', ''MODULE'') = ''Account Payable'' AND
                   SYS_CONTEXT(''USERENV'', ''SESSION_USER'') = ''APPS''');
END;
```

137.5 Summary of DBMS_PRIVILEGE_CAPTURE Subprograms

This table lists and briefly describes the `DBMS_PRIVILEGE_CAPTURE` package subprograms.

Table 137-2 DBMS_PRIVILEGE_CAPTURE Package Subprograms

Subprogram	Description
CAPTURE_DEPENDENCY_PRIVS Procedure	Captures the privileges that are used by definer's rights and invoker's rights PL/SQL program units for compilation.
CREATE_CAPTURE Procedure	Creates a policy that specifies the conditions for analyzing privilege use.
DELETE_RUN Procedure	Deletes a privilege analysis capture run
DISABLE_CAPTURE Procedure	Stops the recording of privilege use for a specified privilege analysis policy
DROP_CAPTURE Procedure	Removes a privilege analysis policy together with the data recorded
ENABLE_CAPTURE Procedure	Starts the recording of privilege analysis for a specified privilege analysis policy
GENERATE_RESULT Procedure	Populates the privilege analysis data dictionary views with data

137.5.1 CAPTURE_DEPENDENCY_PRIVS Procedure

This procedure captures the privileges that are used by definer's rights and invoker's rights PL/SQL program units for compilation.

Syntax

```
DBMS_PRIVILEGE_CAPTURE.CAPTURE_DEPENDENCY_PRIVS ();
```

Parameters

This procedure has no parameters.

Usage Notes

Every rerun of the `DBMS_PRIVILEGE_CAPTURE.CAPTURE_DEPENDENCY_PRIVS` procedure deletes any existing records from the privilege analysis data dictionary views. It then recaptures records based on the existing PL/SQL program units.

137.5.2 CREATE_CAPTURE Procedure

This procedure creates a privilege analysis policy that specifies the conditions for analyzing privilege use. It also optionally specifies the roles for which privilege use is to be analyzed, and the conditions under which privilege use is to be analyzed.

Syntax

```
DBMS_PRIVILEGE_CAPTURE.CREATE_CAPTURE (
   name            IN  VARCHAR2,
   description     IN  VARCHAR2 DEFAULT NULL,
   type            IN  NUMBER DEFAULT G_DATABASE,
   roles           IN  ROLE_NAME_LIST DEFAULT ROLE_NAME_LIST(),
   condition       IN  VARCHAR2 DEFAULT NULL);
```

Parameters

Table 137-3 CREATE_CAPTURE Procedure Parameters

Parameter	Description
`name`	Name of the privilege analysis policy. A string of size up to 30 characters.
`description`	Description of the policy (up to 1024 characters)
`type`	Type of the privilege analysis policy. Possible values are: • `G_DATABASE`: Captures all privilege use in the database, except privileges used by the SYS user. • `G_ROLE`: Captures the use of a privilege if the privilege is part of a specified role or list of roles. • `G_CONTEXT`: Captures the use of a privilege if the context specified by the `condition` parameter evaluates to true. • `G_ROLE_AND_CONTEXT`: Captures the use of a privilege if the privilege is part of the specified list of roles and when the condition specified by the `condition` parameter is true.
`roles`	The roles whose privileges are to be analyzed. Required if the `type` is `G_ROLE` or `G_ROLE_AND_CONTEXT`.
`condition`	PL/SQL boolean expression containing up to 4000 characters. Required if `type` is `G_CONTEXT` or `G_ROLE_AND_CONTEXT`. Note that the boolean expression can only contain `SYS_CONTEXT`, but not other functions.

Usage Notes

- When using role-based analysis for the `CREATE_CAPTURE` procedure, privilege use is analyzed even if the privilege is indirectly granted to the specified role.

  For example, say role R2 contains role R1, and R1 contains privilege P1. If the privilege policy includes only role R2, any use of the P1 privilege is still analyzed, as privilege P1 is an indirect part of role R2.

- When using the `condition` parameter, use the following syntax for the PL/SQL expression:

  ```
  condition::= predicate | (predicate1) AND (predicate2)
  | (predicate1) OR (predicate2)
  ```

Where,

```
predicate::= sys_context(namespace, attribute) relop constant_value |
sys_context(namespace, attribute) between constant_value and
 constant_value | sys_context(namespace, attribute) in {constant_value
(,constant_value)* }
```

Where,

```
relop::= = | < | <= | > | >= | <>
```

- A privilege analysis policy cannot analyze the use of SYS user privileges.

137.5.3 DELETE_RUN Procedure

This procedure deletes a privilege analysis capture run.

Syntax

```
DBMS_PRIVILEGE_CAPTURE.DELETE_RUN (
   name      IN VARCHAR2,
   run_name  IN VARCHAR2);
```

Parameters

Table 137-4 *DELETE_RUN Procedure Parameters*

Parameter	Description
name	Name of the privilege analysis policy with which the capture run is associated
run_name	Name of the capture run

Usage Notes

- You can find the names of existing privilege capture policies by querying the DBA_PRIV_CAPTURES data dictionary view.
- Another way to delete a capture run is to drop the policy with which the capture run is associated. Dropping the policy automatically drops its associated capture runs.
- When you drop a capture run it is no longer accessible through the privilege capture data dictionary views.

137.5.4 DISABLE_CAPTURE Procedure

This procedure stops the recording of privilege use for a specified privilege analysis policy. When a policy is disabled, privilege use meeting the policy condition is no longer recorded.

Syntax

```
DBMS_PRIVILEGE_CAPTURE.DISABLE_CAPTURE (
   name        IN VARCHAR2);
```

Parameters

Table 137-5 DISABLE_CAPTURE Procedure Parameters

Parameter	Description
name	Name of the privilege analysis policy to be disabled

Usage Notes

When a privilege analysis policy is first created, it is disabled by default.

137.5.5 DROP_CAPTURE Procedure

This procedure removes a privilege analysis policy together with the data recorded. When a policy is removed, all previously recorded privilege use data associated with the policy is deleted.

Syntax

```
DBMS_PRIVILEGE_CAPTURE.DROP_CAPTURE (
   name      IN VARCHAR2);
```

Parameters

Table 137-6 *DROP_CAPTURE Procedure Parameters*

Parameter	Description
name	Name of the privilege analysis policy to be removed

Usage Notes

- You must disable a privilege analysis policy before removing it. An enabled policy cannot be removed.
- If there are capture runs associated with this policy, then they are automatically dropped when you drop the policy.

137.5.6 ENABLE_CAPTURE Procedure

This procedure starts the recording of privilege analysis for a specified privilege analysis policy and optionally provides a capture run for this policy. After a policy is enabled, all privilege use under the policy condition is recorded.

Syntax

```
DBMS_PRIVILEGE_CAPTURE.ENABLE_CAPTURE (
   name      IN VARCHAR2,
   run_name  IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 137-7 *ENABLE_CAPTURE Procedure Parameters*

Parameter	Description
`name`	Name of the privilege analysis policy to be enabled
`run_name`	Name of the capture run to associate with this policy, less than 128 characters. Enclose exotic characters in double quotation marks.

Usage Notes

The following usage notes apply:

- When a privilege analysis policy is first created, it is disabled by default. You must run `ENABLE_CAPTURE` to enable the privilege analysis policy.
- You can enable only one privilege analysis policy at a time. However, a database-wide privilege analysis of the `G_DATABASE` type can be enabled together with another non `G_DATABASE` privilege analysis.
- You cannot enable the same run multiple times. For example, `run_01` cannot be used again if you want to re-enable the capture for `run_01`. Instead, create a new run.

137.5.7 GENERATE_RESULT Procedure

This procedure populates the privilege analysis data dictionary views with data.

> **See Also:**
>
> Oracle® Database Security Guide for more information about privilege analysis views.

Syntax

```
DBMS_PRIVILEGE_CAPTURE.GENERATE_RESULT (
   name        IN VARCHAR2,
   run_name    IN VARCHAR2 DEFAULT NULL,
   DEPENDENCY  IN BOOLEAN DEFAULT NULL);
```

Parameters

Table 137-8 *GENERATE_RESULT Procedure Parameters*

Parameter	Description
`name`	Name of the privilege analysis policy for which views are populated
`run_name`	Name of the capture run that is associated with the privilege analysis policy. If you omit this parameter, then the records of all created runs will be analyzed. When you specify the `run_name` parameter, only the records of that run are analyzed and all other runs are unaffected.

Table 137-8 (Cont.) *GENERATE_RESULT Procedure Parameters*

Parameter	Description
dependency	Enter Y (yes) or N (no) to indicate if PL/SQL compilation privileges, set by the DBMS_PRIVILEGE_CAPTURE.CAPTURE_DEPENDENCY_PRIVS procedure, should be included in the report.

Usage Notes

You must disable a privilege analysis policy before populating the privilege analysis views for the policy. You cannot invoke this subprogram on an enabled privilege analysis policy.

138
DBMS_PROCESS

The DBMS_PROCESS package provides an interface to manage the prespawned servers.

This chapter contains the following topics:

- DBMS_PROCESS Overview
- DBMS_PROCESS Security Model
- Summary of DBMS_PROCESS Subprograms

138.1 DBMS_PROCESS Overview

By default, Oracle Database can prespawn foreground processes to improve the performance of client connections.

A prespawned process refers to a process that has been spawned but does not have a session yet. When a user connects to the database or a service process is needed, the process performs further initialization as needed.

To manage foreground processes, use the DBMS_PROCESS package. The procedures in this package configure the number of foreground processes for a connection pool, start a connection pool, and stop a connection pool.

See Also:

- *Oracle Database Administrator's Guide* for a detailed description of managing a pre-created processes
- *Oracle Database Reference* for information about the USE_DEDICATED_BROKER parameter, which determines how dedicated servers are spawned. TRUE enables the listener to send the connection to a dedicated connection broker that spawns the dedicated server. FALSE sets the listener to spawn a dedicated server directly.

138.2 DBMS_PROCESS Security Model

You must be granted the SYSDBA administrative privilege to use the DBMS_PROCESS package.

138.3 Summary of DBMS_PROCESS Subprograms

This table lists the DBMS_PROCESS subprograms and briefly describes them.

Table 138-1 DBMS_PROCESS Package Subprograms

Subprogram	Description
CONFIGURE_POOL Procedure	Configures the minimum number of prespawned processes, the number of prespawned processes in a batch, and the initial number of pre-spawned processes for a foreground connection pool
START_POOL Procedure	Starts a prespawned foreground process pool.
STOP_POOL Procediure	Stops a prespawned foreground process pool.

138.3.1 CONFIGURE_POOL Procedure

This procedure configures the minimum number of prespawned processes, the number of prespawned processes in a batch, and the initial number of pre-spawned processes for a foreground connection pool.

Syntax

```
DBMS_PROCESS.CONFIGURE_POOL(
   pool_name       IN  VARCHAR2 DEFAULT "SYS_DEFAULT_FOREGROUND_POOL",
   min_count       IN  NUMBER DEFAULT 10,
   batch_count     IN  NUMBER DEFAULT 20,
   init_count      IN  NUMBER DEFAULT 0);
```

Parameters

Table 138-2 CONFIGURE_POOL Procedure Parameters

Parameter	Description
pool_name	Name of the foreground pool
min_count	Count after which a batch of prespawned processes will be spawned in the pool (default 10; maximum number of processes 64,000)
batch_count	Batch of prespawned servers to be spawned in the pool (default 20). The total value of the min_count and batch_count values cannot exceed the PROCESSES parameter value.
init_count	Set of prespawned servers to be spawned in startup, or before a storm of connections, spawned in batches (default 0). Do not exceed the PROCESSES parameter value.

Exceptions

Table 138-3 CONFIGURE_POOL Procedure Exceptions

Error	Description
ORA-456	Prespawn not enabled
ORA-457	Prespawn pool not found
ORA-458	Prespawn pool already started
ORA-459	Prespawn pool not started
ORA-460	Process pool invalid configuration value(s)

Usage Notes

- To find information about foreground processes, query the V$PROCESS_POOL dynamic view.

Example

```
BEGIN
  DBMS_PROCESS.CONFIGURE_POOL (
   pool_name   => 'hrdb_pool',
   min_count   => 40,
   batch_count => 20,
   init_count  => 10);
END;
/
```

138.3.2 START_POOL Procedure

This procedure starts a prespawned foreground process pool.

Syntax

```
DBMS_PROCESS.START_POOL(
   pool_name      IN  VARCHAR2 DEFAULT "SYS_DEFAULT_FOREGROUND_POOL");
```

Parameters

Table 138-4 START_POOL Procedure Parameters

Parameter	Description
pool_name	Name of prespawned foreground process pool. To find existing pools, query the V$PROCESS_POOL dynamic view.

Exceptions

Table 138-5 START_POOL Procedure Exceptions

Error	Description
ORA-457	Prespawn pool not found
ORA-458	Prespawn pool already started
ORA-459	Prespawn pool not started

Example

```
BEGIN
  DBMS_PROCESS.START_POOL (
   pool_name   => 'hrdb_pool',
END;
```

138.3.3 STOP_POOL Procedure

This procedure stops a prespawned foreground process pool.

Syntax

```
DBMS_PROCESS.STOP_POOL(
   pool_name      IN  VARCHAR2 DEFAULT "SYS_DEFAULT_FOREGROUND_POOL");
```

Parameters

Table 138-6 STOP_POOL Procedure Parameters

Parameter	Description
pool_name	Name of the prespawned foreground process pool. To find existing pools, query the V$PROCESS_POOL dynamic view.

Exceptions

Table 138-7 STOP_POOL Procedure Exceptions

Error	Description
ORA-457	Prespawn pool not found
ORA-458	Prespawn pool already started
ORA-459	Prespawn pool not started

Example

```
BEGIN
  DBMS_PROCESS.STOP_POOL (
   pool_name   => 'hrdb_pool',
END;
```

139
DBMS_PROFILER

The package provides an interface to profile existing PL/SQL applications and identify performance bottlenecks. You can then collect and persistently store the PL/SQL profiler data.

This chapter contains the following topics:

- Overview
- Security Model
- Operational Notes
- Exceptions
- Summary of DBMS_PROFILER Subprograms

139.1 DBMS_PROFILER Overview

This package enables the collection of profiler (performance) data for performance improvement or for determining code coverage for PL/SQL applications. Application developers can use code coverage data to focus their incremental testing efforts.

With this interface, you can generate profiling information for all named library units that are executed in a session. The profiler gathers information at the PL/SQL virtual machine level. This information includes the total number of times each line has been executed, the total amount of time that has been spent executing that line, and the minimum and maximum times that have been spent on a particular execution of that line.

> **Note:**
>
> It is possible to infer the code coverage figures for PL/SQL units for which data has been collected.

The profiling information is stored in database tables. This enables querying on the data: you can build customizable reports (summary reports, hottest lines, code coverage data, and so on. And you can analyze the data.

The `PROFTAB.SQL` script creates tables with the columns, datatypes, and definitions as shown in the following tables.

Table 139-1 Columns in Table PLSQL_PROFILER_RUNS

Column	Datatype	Definition
`runid`	`NUMBER PRIMARY KEY`	Unique run identifier from plsql_profiler_runnumber
`related_run`	`NUMBER`	Runid of related run (for client/server correlation)

Table 139-1 (Cont.) Columns in Table PLSQL_PROFILER_RUNS

Column	Datatype	Definition
run_owner	VARCHAR2(128)	User who started run
run_date	DATE	Start time of run
run_comment	VARCHAR2(2047)	User provided comment for this run
run_total_time	NUMBER	Elapsed time for this run in nanoseconds
run_system_info	VARCHAR2(2047)	Currently unused
run_comment1	VARCHAR2(2047)	Additional comment
spare1	VARCHAR2(256)	Unused

Table 139-2 Columns in Table PLSQL_PROFILER_UNITS

Column	Datatype	Definition
runid	NUMBER	Primary key, references plsql_profiler_runs,
unit_number	NUMBER	Primary key, internally generated library unit #
unit_type	VARCHAR2(128)	Library unit type
unit_owner	VARCHAR2(128)	Library unit owner name
unit_name	VARCHAR2(128)	Library unit name timestamp on library unit
unit_timestamp	DATE	In the future will be used to detect changes to unit between runs
total_time	NUMBER	Total time spent in this unit in nanoseconds. The profiler does not set this field, but it is provided for the convenience of analysis tools.
spare1	NUMBER	Unused
spare2	NUMBER	Unused

Table 139-3 Columns in Table PLSQL_PROFILER_DATA

Column	Datatype	Definition
runid	NUMBER	Primary key, unique (generated) run identifier
unit_number	NUMBER	Primary key, internally generated library unit number
line#	NUMBER	Primary key, not null, line number in unit
total_occur	NUMBER	Number of times line was executed
total_time	NUMBER	Total time spent executing line in nanoseconds
min_time	NUMBER	Minimum execution time for this line in nanoseconds
max_time	NUMBER	Maximum execution time for this line in nanoseconds
spare1	NUMBER	Unused
spare2	NUMBER	Unused
spare3	NUMBER	Unused
spare4	NUMBER	Unused

With Oracle database version 8.x, a sample textual report writer(profrep.sql) is provided with the PL/SQL demo scripts.

Note that prior to Oracle Database 10*g*, the `DBMS_PROFILER` package was not automatically loaded when the database was created, and the Oracle-supplied `PROFLOAD.SQL` script was used to create it. In 10*g* and beyond, the `DBMS_PROFILER` package is loaded automatically when the database is created, and `PROFLOAD.SQL` is no longer needed.

139.2 DBMS_PROFILER Security Model

The profiler only gathers data for units for which a user has `CREATE` privilege; you cannot use the package to profile units for which `EXECUTE ONLY` access has been granted. In general, if a user can debug a unit, the same user can profile it. However, a unit can be profiled whether or not it has been compiled `DEBUG`. Oracle advises that modules that are being profiled should be compiled `DEBUG`, since this provides additional information about the unit in the database.

> **Note:**
>
> `DBMS_PROFILER` treats any program unit that is compiled in `NATIVE` mode as if you do not have `CREATE` privilege, that is, you will not get any output.

139.3 DBMS_PROFILER Operational Notes

These notes describe a typical run, how to interpret output, and two methods of exception generation.

Typical Run

Improving application performance is an iterative process. Each iteration involves the following steps:

1. Running the application with one or more benchmark tests with profiler data collection enabled.
2. Analyzing the profiler data and identifying performance problems.
3. Fixing the problems.

The PL/SQL profiler supports this process using the concept of a *"run".* A run involves running the application through benchmark tests with profiler data collection enabled. You can control the beginning and the ending of a run by calling the `START_PROFILER` and `STOP_PROFILER` functions.

The user must first create database tables in the profiler user's schema to collect the data. The `PROFTAB.SQL` script creates the tables and other data structures required for persistently storing the profiler data.

Note that running `PROFTAB.SQL` drops the current tables. The `PROFTAB.SQL` script is in the `RDBMS/ADMIN` directory. Some PL/SQL operations, such as the first execution of a PL/SQL unit, may involve I/O to catalog tables to load the byte code for the PL/SQL unit being executed. Also, it may take some time executing package initialization code the first time a package procedure or function is called.

To avoid timing this overhead, "*warm up*" the database before collecting profile data. To do this, run the application once without gathering profiler data.

You can allow profiling across all users of a system, for example, to profile all users of a package, independent of who is using it. In such cases, the `SYSADMIN` should use a modified `PROFTAB.SQL` script which:

- Creates the profiler tables and sequence
- Grants `SELECT/INSERT/UPDATE` on those tables and sequence to all users
- Defines public synonyms for the tables and sequence

> **Note:**
>
> Do not alter the actual fields of the tables.

A typical run then involves:

- Starting profiler data collection in the run.
- Executing PL/SQL code for which profiler and code coverage data is required.
- Stopping profiler data collection, which writes the collected data for the run into database tables

> **Note:**
>
> The collected profiler data is not automatically stored when the user disconnects. You must issue an explicit call to the `FLUSH_DATA` or the `STOP_PROFILER` function to store the data at the end of the session. Stopping data collection stores the collected data.

As the application executes, profiler data is collected in memory data structures that last for the duration of the run. You can call the `FLUSH_DATA` function at intermediate points during the run to get incremental data and to free memory for allocated profiler data structures. Flushing the collected data involves storing collected data in the database tables created earlier.

> **See Also:**
>
> "FLUSH_DATA Function and Procedure".

Interpreting Output

The table `plsql_profiler_data` contains one row for each line of the source unit for which code was generated. The line# value specifies which source line. If the row exists, and the total_occur value in that row is > 0, some code associated with that line was executed. If the row exists, and total_occur value is 0, no code associated with that line was executed. If the row doesn't exist in the table, no code was generated for that line, and therefore it should not be mentioned in reports

If the source of a single statement is on a single line, any code generated for that statement will be attributed to that line number. (In some cases, such as a simple declaration, or because of optimization, no code will be needed). To get coverage information, units should be compiled with `PLSQL_OPTIMIZE_LEVEL=1`.

If a statement spans multiple lines, any code generated for that statement will be attributed to some line in the range, but it is not guaranteed that every line in the range will have code attributed to it. In such a case there will be gaps in the set of line# values. In particular, multi-line SQL-related statements may appear to be on a single line (usually the first). This is because PL/SQL passes the processed text of the cursor to the SQL engine; therefore, as far as PL/SQL is concerned, the entire SQL statement is a single indivisible operation.

When multiple statements are on the same line, the profiler will combine the occurrences for each statement. This may be confusing if a line has embedded control flow. For example, if `'then ...'` and `'else ...'` are on the same line, it will not be possible to determine whether the `'then'` or the `'else'` was taken.

In general, profiler and coverage reports are most easily interpreted if each statement is on its own line.

Two Methods of Exception Generation

Each routine in this package has two versions that allow you to determine how errors are reported.

- A function that returns success/failure as a status value and will never raise an exception
- A procedure that returns normally if it succeeds and raises an exception if it fails

In each case, the parameters of the function and procedure are identical. Only the method by which errors are reported differs. If there is an error, there is a correspondence between the error codes that the functions return, and the exceptions that the procedures raise.

To avoid redundancy, the following section only provides details about the functional form.

139.4 DBMS_PROFILER Exceptions

DBMS_PROFILER throws the exceptions described in this topic.

Table 139-4 DBMS_PROFILER Exceptions

Exception	Description
`version_mismatch`	Corresponds to error_version.
`profiler_error`	Corresponds to either "error_param" or "error_io".

A `0` return value from any function denotes successful completion; a nonzero return value denotes an error condition. The possible errors are as follows:

- 'A subprogram was called with an incorrect parameter.'

  ```
  error_param constant binary_integer := 1;
  ```

- 'Data flush operation failed. Check whether the profiler tables have been created, are accessible, and that there is adequate space.'

```
error_io    constant binary_integer := 2;
```

- There is a mismatch between package and database implementation. Oracle returns this error if an incorrect version of the `DBMS_PROFILER` package is installed, and if the version of the profiler package cannot work with this database version. The only recovery is to install the correct version of the package.

```
error_version constant binary_integer := -1;
```

139.5 Summary of DBMS_PROFILER Subprograms

This table lists the `DBMS_PROFILER` subprograms and briefly describes them.

Table 139-5 DBMS_PROFILER Package Subprograms

Subprogram	Description
FLUSH_DATA Function and Procedure	Flushes profiler data collected in the user's session
GET_VERSION Procedure	Gets the version of this API
INTERNAL_VERSION_CHECK Function	Verifies that this version of the `DBMS_PROFILER` package can work with the implementation in the database
PAUSE_PROFILER Function and Procedure	Pauses profiler data collection
RESUME_PROFILER Function and Procedure	Resumes profiler data collection
START_PROFILER Functions and Procedures	Starts profiler data collection in the user's session
STOP_PROFILER Function and Procedure	Stops profiler data collection in the user's session

139.5.1 FLUSH_DATA Function and Procedure

This function flushes profiler data collected in the user's session. The data is flushed to database tables, which are expected to preexist.

> **Note:**
>
> Use the `PROFTAB.SQL` script to create the tables and other data structures required for persistently storing the profiler data.

Syntax

```
DBMS_PROFILER.FLUSH_DATA
  RETURN BINARY_INTEGER;

DBMS_PROFILER.FLUSH_DATA;
```

139.5.2 GET_VERSION Procedure

This procedure gets the version of this API.

Syntax

```
DBMS_PROFILER.GET_VERSION (
   major  OUT BINARY_INTEGER,
   minor  OUT BINARY_INTEGER);
```

Parameters

Table 139-6 GET_VERSION Procedure Parameters

Parameter	Description
major	Major version of DBMS_PROFILER.
minor	Minor version of DBMS_PROFILER.

139.5.3 INTERNAL_VERSION_CHECK Function

This function verifies that this version of the DBMS_PROFILER package can work with the implementation in the database.

Syntax

```
DBMS_PROFILER.INTERNAL_VERSION_CHECK
  RETURN BINARY_INTEGER;
```

139.5.4 PAUSE_PROFILER Function and Procedure

This function pauses profiler data collection.

Syntax

```
DBMS_PROFILER.PAUSE_PROFILER
  RETURN BINARY_INTEGER;

DBMS_PROFILER.PAUSE_PROFILER;
```

139.5.5 RESUME_PROFILER Function and Procedure

This function resumes profiler data collection.

Syntax

```
DBMS_PROFILER.RESUME_PROFILER
  RETURN BINARY_INTEGER;

DBMS_PROFILER.RESUME_PROFILER;
```

139.5.6 START_PROFILER Functions and Procedures

This function starts profiler data collection in the user's session.

There are two overloaded forms of the START_PROFILER function; one returns the run number of the started run, as well as the result of the call. The other does not return the run number. The first form is intended for use with GUI-based tools controlling the profiler.

Syntax

```
DBMS_PROFILER.START_PROFILER(
   run_comment   IN VARCHAR2 := sysdate,
   run_comment1  IN VARCHAR2 :='',
   run_number    OUT BINARY_INTEGER)
 RETURN BINARY_INTEGER;

DBMS_PROFILER.START_PROFILER(
   run_comment IN VARCHAR2 := sysdate,
   run_comment1 IN VARCHAR2 :='')
RETURN BINARY_INTEGER;

DBMS_PROFILER.START_PROFILER(
   run_comment   IN VARCHAR2 := sysdate,
   run_comment1  IN VARCHAR2 :='',
   run_number    OUT BINARY_INTEGER);

DBMS_PROFILER.START_PROFILER(
   run_comment IN VARCHAR2 := sysdate,
   run_comment1 IN VARCHAR2 :='');
```

Parameters

Table 139-7 START_PROFILER Function Parameters

Parameter	Description
run_comment	Each profiler run can be associated with a comment. For example, the comment could provide the name and version of the benchmark test that was used to collect data.
run_number	Stores the number of the run so you can store and later recall the run's data.
run_comment1	Allows you to make interesting comments about the run.

139.5.7 STOP_PROFILER Function and Procedure

This function stops profiler data collection in the user's session.

This function has the side effect of flushing data collected so far in the session, and it signals the end of a run.

Syntax

```
DBMS_PROFILER.STOP_PROFILER
  RETURN BINARY_INTEGER;
```

```
DBMS_PROFILER.STOP_PROFILER;
```

140
DBMS_PROPAGATION_ADM

The DBMS_PROPAGATION_ADM package, one of a set of Oracle Replication packages, provides administrative interfaces for configuring a propagation from a source queue to a destination queue.

This chapter contains the following topics:

- Overview
- Security Model
- Summary of DBMS_PROPAGATION_ADM Subprograms

140.1 DBMS_PROPAGATION_ADM Overview

This package provides interfaces to start, stop, and configure a propagation.

140.2 DBMS_PROPAGATION_ADM Security Model

Security on this package can be controlled by granting EXECUTE on this package to selected users or roles, or by granting EXECUTE_CATALOG_ROLE to selected users or roles.

If subprograms in the package are run from within a stored procedure, then the user who runs the subprograms must be granted EXECUTE privilege on the package directly. It cannot be granted through a role.

When the DBMS_PROPAGATION_ADM package is used to manage an Oracle Replication configuration, it requires that the user is granted the privileges of an Oracle Replication administrator.

140.3 Summary of DBMS_PROPAGATION_ADM Subprograms

This table lists the DBMS_PROPAGATION_ADM subprograms and briefly describes them.

Table 140-1 DBMS_PROPAGATION_ADM Package Subprograms

Subprogram	Description
ALTER_PROPAGATION Procedure	Adds, alters, or removes a rule set for a propagation
CREATE_PROPAGATION Procedure	Creates a propagation and specifies the source queue, destination queue, and rule set for the propagation
DROP_PROPAGATION Procedure	Drops a propagation
START_PROPAGATION Procedure	Starts a propagation
STOP_PROPAGATION Procedure	Stops a propagation

> **Note:**
>
> All subprograms commit unless specified otherwise.

140.3.1 ALTER_PROPAGATION Procedure

This procedure adds, alters, or removes a rule set for a propagation.

Syntax

```
DBMS_PROPAGATION_ADM.ALTER_PROPAGATION(
   propagation_name          IN  VARCHAR2,
   rule_set_name             IN  VARCHAR2  DEFAULT NULL,
   remove_rule_set           IN  BOOLEAN   DEFAULT FALSE,
   negative_rule_set_name    IN  VARCHAR2  DEFAULT NULL,
   remove_negative_rule_set  IN  BOOLEAN   DEFAULT FALSE);
```

Parameters

Table 140-2 ALTER_PROPAGATION Procedure Parameters

Parameter	Description
`propagation_name`	The name of the propagation you are altering. You must specify an existing propagation name. Do not specify an owner.
`rule_set_name`	The name of the positive rule set for the propagation. The positive rule set contains the rules that instruct the propagation to propagate messages. If you want to use a positive rule set for the propagation, then you must specify an existing rule set in the form `[`*`schema_name`*`.]`*`rule_set_name`*. For example, to specify a positive rule set in the `hr` schema named `prop_rules`, enter `hr.prop_rules`. If the schema is not specified, then the current user is the default. An error is returned if the specified rule set does not exist. You can create a rule set and add rules to it using the `DBMS_RULE_ADM` package. If you specify `NULL` and the `remove_rule_set` parameter is set to `FALSE`, then the procedure retains any existing positive rule set. If you specify `NULL` and the `remove_rule_set` parameter is set to `TRUE`, then the procedure removes any existing positive rule set.

Table 140-2 (Cont.) ALTER_PROPAGATION Procedure Parameters

Parameter	Description
remove_rule_set	If TRUE, then the procedure removes the positive rule set for the specified propagation. If you remove a positive rule set for a propagation, and the propagation does not have a negative rule set, then the propagation propagates all messages. If you remove a positive rule set for a propagation, and a negative rule set exists for the propagation, then the propagation propagates all messages in its queue that are not discarded by the negative rule set. If FALSE, then the procedure retains the positive rule set for the specified propagation. If the rule_set_name parameter is non-NULL, then this parameter should be set to FALSE.
negative_rule_set_name	The name of the negative rule set for the propagation. The negative rule set contains the rules that instruct the propagation to discard messages. If you want to use a negative rule set for the propagation, then you must specify an existing rule set in the form [*schema_name.*]*rule_set_name*. For example, to specify a negative rule set in the hr schema named neg_rules, enter hr.neg_rules. If the schema is not specified, then the current user is the default. An error is returned if the specified rule set does not exist. You can create a rule set and add rules to it using the DBMS_RULE_ADM package. If you specify NULL and the remove_negative_rule_set parameter is set to FALSE, then the procedure retains any existing negative rule set. If you specify NULL and the remove_negative_rule_set parameter is set to TRUE, then the procedure removes any existing negative rule set. If you specify both a positive and a negative rule set for a propagation, then the negative rule set is always evaluated first.
remove_negative_rule_set	If TRUE, then the procedure removes the negative rule set for the specified propagation. If you remove a negative rule set for a propagation, and the propagation does not have a positive rule set, then the propagation propagates all messages. If you remove a negative rule set for a propagation, and a positive rule set exists for the propagation, then the propagation propagates all messages in its queue that are not discarded by the positive rule set. If FALSE, then the procedure retains the negative rule set for the specified propagation. If the negative_rule_set_name parameter is non-NULL, then this parameter should be set to FALSE.

140.3.2 CREATE_PROPAGATION Procedure

This procedure creates a propagation and specifies the source queue, destination queue, and any rule set for the propagation. A propagation propagates messages in a local source queue to a destination queue. The destination queue might or might not be in the same database as the source queue.

Syntax

```
DBMS_PROPAGATION_ADM.CREATE_PROPAGATION(
   propagation_name           IN  VARCHAR2,
   source_queue               IN  VARCHAR2,
   destination_queue          IN  VARCHAR2,
   destination_dblink         IN  VARCHAR2  DEFAULT NULL,
   rule_set_name              IN  VARCHAR2  DEFAULT NULL,
   negative_rule_set_name     IN  VARCHAR2  DEFAULT NULL,
   queue_to_queue             IN  BOOLEAN   DEFAULT NULL,
   original_propagation_name  IN  VARCHAR2  DEFAULT NULL,
   auto_merge_threshold       IN  NUMBER    DEFAULT NULL);
```

Parameters

Table 140-3 CREATE_PROPAGATION Procedure Parameters

Parameter	Description
`propagation_name`	The name of the propagation you are creating. A `NULL` setting is not allowed. Do not specify an owner. **Note:** The `propagation_name` setting cannot be altered after the propagation is created.
`source_queue`	The name of the source queue, specified as `[`*`schema_name`*`.]`*`queue_name`*. The current database must contain the source queue. For example, to specify a source queue named `streams_queue` in the `strmadmin` schema, enter `strmadmin.streams_queue` for this parameter. If the schema is not specified, then the current user is the default.
`destination_queue`	The name of the destination queue, specified as `[`*`schema_name`*`.]`*`queue_name`*. For example, to specify a destination queue named `streams_queue` in the `strmadmin` schema, enter `strmadmin.streams_queue` for this parameter. If the schema is not specified, then the current user is the default.
`destination_dblink`	The name of the database link that will be used by the propagation. The database link is from the database that contains the source queue to the database that contains the destination queue. If `NULL`, then the source queue and destination queue must be in the same database. **Note:** Connection qualifiers are not allowed.

Table 140-3 (Cont.) CREATE_PROPAGATION Procedure Parameters

Parameter	Description
rule_set_name	The name of the positive rule set for the propagation. The positive rule set contains the rules that instruct the propagation to propagate messages. If you want to use a positive rule set for the propagation, then you must specify an existing rule set in the form [*schema_name*.]*rule_set_name*. For example, to specify a positive rule set in the hr schema named prop_rules, enter hr.prop_rules. If the schema is not specified, then the current user is the default. An error is returned if the specified rule set does not exist. You can create a rule set and add rules to it using the DBMS_RULE_ADM package. If you specify NULL, and no negative rule set exists for the propagation, then the propagation propagates all messages in its queue. If you specify NULL, and a negative rule set exists for the propagation, then the propagation propagates all messages in its queue that are not discarded by the negative rule set.
negative_rule_set_name	The name of the negative rule set for the propagation. The negative rule set contains the rules that instruct the propagation to discard messages. If you want to use a negative rule set for the propagation, then you must specify an existing rule set in the form [*schema_name*.]*rule_set_name*. For example, to specify a negative rule set in the hr schema named neg_rules, enter hr.neg_rules. If the schema is not specified, then the current user is the default. An error is returned if the specified rule set does not exist. You can create a rule set and add rules to it using the DBMS_RULE_ADM package. If you specify NULL, and no positive rule set exists for the propagation, then the propagation propagates all messages in its queue. If you specify NULL, and a positive rule set exists for the propagation, then the propagation propagates all messages in its queue that are not discarded by the positive rule set. If you specify both a positive and a negative rule set for a propagation, then the negative rule set is always evaluated first.

Table 140-3 (Cont.) CREATE_PROPAGATION Procedure Parameters

Parameter	Description
queue_to_queue	If TRUE or NULL, then the propagation is a queue to queue propagation. A queue-to-queue propagation always has its own propagation job and uses a service for automatic failover when the destination queue is a buffered queue in an Oracle Real Application Clusters (Oracle RAC) database. If FALSE, then the propagation is a queue-to-dblink propagation. A queue-to-dblink propagation can share a propagation job with other propagations that use the same database link and does not support automatic failover in an Oracle RAC environment.
original_propagation_name	Specify the original propagation name if the propagation being created is part of a split and merge operation. The split operation clones the original propagation under a new name. The name of the original propagation is important when the cloned propagation is copied back to the original stream. Specify NULL if the propagation being created is not part of a split and merge operation.
auto_merge_theshold	Specify a positive number if both of the following conditions are met: • The propagation being created is part of a split and merge operation. • The stream will be merged back to the original stream automatically. Specify NULL if either of the following conditions are met: • The propagation being created is not part of a split and merge operation. • The propagation being created is part of a split and merge operation, but the stream being split off will not be merged back to the original stream automatically.

Usage Notes

This procedure starts propagation and might create a propagation job. If this procedure creates a propagation job, then it establishes a default schedule for the propagation job. Each propagation job is an Oracle Scheduler job. You can adjust the schedule of a propagation job using Oracle Scheduler.

The user who owns the source queue is the user who propagates messages. This user must have the necessary privileges to propagate messages.

> **See Also:**
>
> DBMS_RULE_ADM

140.3.3 DROP_PROPAGATION Procedure

This procedure drops a propagation and deletes all messages for the destination queue in the source queue. This procedure also removes the schedule for propagation from the source queue to the destination queue.

Syntax

```
DBMS_PROPAGATION_ADM.DROP_PROPAGATION(
   propagation_name       IN  VARCHAR2,
   drop_unused_rule_sets  IN  BOOLEAN  DEFAULT FALSE);
```

Parameters

Table 140-4 DROP_PROPAGATION Procedure Parameters

Parameter	Description
propagation_name	The name of the propagation you are dropping. You must specify an existing propagation name. Do not specify an owner.
drop_unused_rule_sets	If TRUE, then the procedure drops any rule sets, positive and negative, used by the specified propagation if these rule sets are not used by any other Oracle Replication client, which includes capture processes, propagations, apply processes, and messaging clients. If this procedure drops a rule set, then this procedure also drops any rules in the rule set that are not in another rule set. If FALSE, then the procedure does not drop the rule sets used by the specified propagation, and the rule sets retain their rules.

Usage Notes

When you use this procedure to drop a propagation, information about rules created for the propagation is removed from the data dictionary views for Oracle Replication rules. Information about such a rule is removed even if the rule is not in either rule set for the propagation.

The following are the data dictionary views for Oracle Replication rules:

- ALL_STREAMS_GLOBAL_RULES
- DBA_STREAMS_GLOBAL_RULES
- ALL_STREAMS_SCHEMA_RULES
- DBA_STREAMS_SCHEMA_RULES
- ALL_STREAMS_TABLE_RULES
- DBA_STREAMS_TABLE_RULES

> **Note:**
>
> When you drop a propagation, the propagation job used by the propagation is dropped automatically, if no other propagations are using the propagation job.

140.3.4 START_PROPAGATION Procedure

This procedure starts a propagation.

Syntax

```
DBMS_PROPAGATION_ADM.START_PROPAGATION(
   propagation_name  IN  VARCHAR2);
```

Parameter

Table 140-5 START_PROPAGATION Procedure Parameter

Parameter	Description
propagation_name	The name of the propagation you are starting. You must specify an existing propagation name. Do not specify an owner.

Usage Notes

The propagation status is persistently recorded. Hence, if the status is ENABLED, then the propagation is started upon database instance startup.

140.3.5 STOP_PROPAGATION Procedure

This procedure stops a propagation.

Syntax

```
DBMS_PROPAGATION_ADM.STOP_PROPAGATION(
   propagation_name  IN  VARCHAR2,
   force             IN  BOOLEAN  DEFAULT FALSE);
```

Parameter

Table 140-6 STOP_PROPAGATION Procedure Parameter

Parameter	Description
propagation_name	The name of the propagation you are stopping. You must specify an existing propagation name. Do not specify an owner.
force	If TRUE, then the procedure stops the propagation and clears the statistics for the propagation. If FALSE, then the procedure stops the propagation without clearing the statistics for the propagation.

Usage Notes

The propagation status is persistently recorded. Hence, if the status is DISABLED or ABORTED, then the propagation is not started upon database instance startup.

141
DBMS_QOPATCH

The DBMS_QOPATCH package provides an interface to view the installed database patches.

This chapter contains the following topics:

- Overview
- Security Modell
- Operational Notes
- Error Messages
- Summary of DBMS_QOPATCH Subprograms

141.1 DBMS_QOPATCH Overview

The DBMS_QOPATCH package provides a PLSQL/SQL interface to view the installed database patches. The interface provides all the patch information available as part of the OPATCH LSINVENTORY -XML command. The package accesses the OUI patch inventory in real time to provide patch and meta-information.

141.2 DBMS_QOPATCH Security Model

The DBMS_QOPATCH package is created as part of SYS schema and SYS is the only user who can execute these subprograms.

141.3 DBMS_QOPATCH Operational Notes

The following operational notes apply to DBMS_QOPATCH.

- The package will work only if the database is OPEN.
- In an Oracle Real Application Clusters (RAC) environment, if the subprogram requires to fetch data from other RAC nodes it spawns a job in the other node(s) to get the data. In this case JOB_QUEUE_PROCESSES needs to be >0 for the package to fetch the data from other RAC nodes.
- If there is a delay in the job execution, the package returns ORA-20008 error.

141.4 DBMS_QOPATCH Exceptions

This table lists the exceptions raised by the DBMS_QOPATCH package.

Table 141-1 DBMS_QOPATCH Error Messages

Error Code	Description
ORA-20001	Latest XML inventory is not loaded into table.

Table 141-1 (Cont.) DBMS_QOPATCH Error Messages

Error Code	Description
ORA-20002	Directory creation failed.
ORA-20003	Configuration of a job on a node failed.
ORA-20004	Job configuration failed as node is inactive.
ORA-20005	Job is not configured with given node, instance name.
ORA-20006	Number of RAC active instances and opatch jobs configured are not same.
ORA-20007	Job configuration failed as node or instance is not active.
ORA-20008	Timed out - job execution time is more than 120Secs.
ORA-20009	Job execution failed.
ORA-20010	Node is inactive and job cannot be executed.
ORA-20011	Job name is NULL and inventory cannot be loaded.
ORA-20012	JOB_QUEUE_PROCESSES is set to zero and the inventory cannot be loaded.
ORA-20013	DBMS_QOPATCH ran mostly in non-install area.
ORA-20014	Database is not opened.
ORA-20015	Database opened as read-only.

141.5 Summary of DBMS_QOPATCH Subprograms

This table lists and briefly describes the DBMS_QOPATCH package subprograms.

Table 141-2 DBMS_QOPATCH Package Subprograms

Subprogram	Description
CHECK_PATCH_INSTALLED Function	Checks if a patch is installed.
GET_OPATCH_BUGS Function	Provides a bugs list for a patch in XML format if the patch number is given. If patch is not given then it lists all the bugs installed in all the patches in XML format.
GET_OPATCH_COUNT Function	Provides the total number of installed patches in XML format
GET_OPATCH_DATA Function	Provides top level patch information for the patch (such as Patch ID, patch creation time) in the XML element
GET_OPATCH_FILES Function	Provides the list of files modified in the given patch number in XML format
GET_OPATCH_INSTALL_INFO Function	Returns the XML element containing the ORACLE_HOME details such as patch and inventory location
GET_OPATCH_LIST Function	Provides list of patches installed as an XML element from the XML inventory
GET_OPATCH_LSINVENTORY	Returns whole opatch inventory as XML instance document.
GET_OPATCH_OLAYS Function	Provides overlay patches for a given patch as XML element

Table 141-2 (Cont.) DBMS_QOPATCH Package Subprograms

Subprogram	Description
GET_OPATCH_PREQS Function	Provides prerequisite patches for a given patch as XML element
GET_OPATCH_XSLT	Returns the style-sheet for the opatch XML inventory presentation
GET_PATCH_DETAILS Function	Displays the detailed patch information from `opatch lsinventory`.
GET_SQLPATCH_STATUS Procedure	Displays the SQL patch status by querying from SQL patch registry to produce complete patch level information
IS_PATCH_INSTALLED Function	Provides information (such as patchID, application date, and SQL patch information) on the installed patch as XML node by querying the XML inventory
OPATCH_COMPARE_CURRENT Function	Compares the current database with a list of bugs.
OPATCH_COMPARE_NODES Function	Compares the given RAC node(s) with the instance to the present connected node with current node. The return value indicates whether the data was refreshed or not.
SET_CURRENT_OPINST Procedure	Sets the node name and instance to get the inventory details specific to it in an Oracle Real Application Clusters (RAC) environment

141.5.1 CHECK_PATCH_INSTALLED Function

Checks if the patch is installed.

Syntax

```
DBMS_QOPATCH.CHECK_PATCH_INSTALLED (
   bugs     IN QOPATCH_LIST);
 RETURN VARCHAR2;
```

Parameters

Table 141-3 CHECK_PATCH_INSTALLED Parameters

Parameter	Description
bugs	List of patches to be checked.

141.5.2 GET_OPATCH_BUGS Function

This function provides a bugs list in a patch if the patch number is given. If a patch number is not given, it lists all the bugs in the specified XML format.

Syntax

```
DBMS_QOPATCH.GET_OPATCH_BUGS (
   patchnum IN VARCHAR2 DEFAULT NULL);
 RETURN XMLTYPE;
```

Parameters

Table 141-4 GET_OPATCH_BUGS Function Parameters

Parameter	Description
patchnum	Patch number

141.5.3 GET_OPATCH_COUNT Function

This function provides the total number of installed patches in XML format.

Syntax

```
DBMS_QOPATCH.GET_OPATCH_COUNT (
   patchnum IN VARCHAR2);
 RETURN XMLTYPE;
```

Parameters

Table 141-5 GET_OPATCH_COUNT Function Parameters

Parameter	Description
patchnum	Patch number

141.5.4 GET_OPATCH_DATA Function

This function provides top level patch information for the patch (such as Patch ID, patch creation time) in the XML element.

Syntax

```
DBMS_QOPATCH.GET_OPATCH_DATA (
   patchnum IN VARCHAR2);
 RETURN XMLTYPE;
```

Parameters

Table 141-6 GET_OPATCH_DATA Function Parameters

Parameter	Description
patchnum	Patch number

141.5.5 GET_OPATCH_FILES Function

This function provides the list of files modified in the given patch number in XML format.

Syntax

```
DBMS_QOPATCH.GET_OPATCH_FILES (
   patchnum IN VARCHAR2);
 RETURN XMLTYPE;
```

Parameters

Table 141-7 GET_OPATCH_FILES Function Parameters

Parameter	Description
patchnum	Patch number

141.5.6 GET_OPATCH_INSTALL_INFO Function

This function returns the XML element containing the ORACLE_HOME details such as patch and inventory location.

Syntax

```
DBMS_QOPATCH.GET_OPATCH_INSTALL_INFO
 RETURNS XMLTYPE;
```

141.5.7 GET_OPATCH_LIST Function

This function provides list of patches installed as an XML element from the XML inventory.

Syntax

```
DBMS_QOPATCH.GET_OPATCH_LIST
 RETURN XMLTYPE;
```

141.5.8 GET_OPATCH_LSINVENTORY

This function returns whole opatch inventory as XML instance document.

Syntax

```
DBMS_QOPATCH.GET_OPATCH_LSINVENTORY
 RETURN XMLTYPE;
```

141.5.9 GET_OPATCH_OLAYS Function

This function provides overlay patches for a given patch as XML element.

Syntax

```
DBMS_QOPATCH.GET_OPATCH_OLAYS (
   patchnum IN VARCHAR2);
 RETURN XMLTYPE;
```

Parameters

Table 141-8 GET_OPATCH_OLAYS Function Parameters

Parameter	Description
patchnum	Patch number

141.5.10 GET_OPATCH_PREQS Function

This function provides prerequisite patches for a given patch as XML element.

Syntax

```
DBMS_QOPATCH.GET_OPATCH_PREQS (
   patchnum IN VARCHAR2);
 RETURN XMLTYPE;
```

Parameters

Table 141-9 GET_OPATCH_PREQS Function Parameters

Parameter	Description
patchnum	Patch number

141.5.11 GET_OPATCH_XSLT

This function returns the style-sheet for the opatch XML inventory presentation. You can use the return type of this subprogram to perform XMLTRANSFORM and the transformed result has the same appearance as opatch text output.

Syntax

```
DBMS_QOPATCH.GET_OPATCH_XSLT
 RETURN XMLTYPE;
```

141.5.12 GET_PATCH_DETAILS Function

Displays the detailed patch information from `opatch lsinventory`.

Syntax

```
DBMS_QOPATCH.GET_PATCH_DETAILS (
   patch    IN VARCHAR2);
 RETURN XMLTYPE;
```

Parameters

Table 141-10 GET_PATCH_DETAILS Function Parameters

Parameter	Description
patch	The patch number.

141.5.13 GET_SQLPATCH_STATUS Procedure

This procedure displays the SQL patch status by querying from SQL patch registry to produce complete patch level information. If the patch number is given, it displays the information specific to the given SQL patch, otherwise information for all SQL patches.

Syntax

```
DBMS_QOPATCH.GET_SQLPATCH_STATUS (
   patchnum IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 141-11 GET_SQLPATCH_STATUS Procedure Parameters

Parameter	Description
patchnum	Patch number

141.5.14 IS_PATCH_INSTALLED Function

This function provides information (such as patchID, application date, and SQL patch information) on the installed patch as XML node by querying the XML inventory.

Syntax

```
DBMS_QOPATCH.IS_PATCH_INSTALLED (
   patchnum IN VARCHAR2);
 RETURN XMLTYPE;
```

Parameters

Table 141-12 IS_PATCH_INSTALLED Function Parameters

Parameter	Description
patchnum	Patch number

141.5.15 OPATCH_COMPARE_CURRENT Function

Compares the current database with a list of bugs.

Syntax

```
DBMS_QOPATCH.OPATCH_COMPARE_CURRENT Function (
   bugs     IN QOPATCH_LIST);
 RETURN VARCHAR2;
```

Parameters

Table 141-13 OPATCH_COMPARE_CURRENT Function Parameters

Parameter	Description
bugs	List of bugs to compare with the current database.

141.5.16 OPATCH_COMPARE_NODES Function

Compares the given RAC node(s) with the instance to the present connected node with current node. The return value indicates whether the data was refreshed or not.

Syntax

```
DBMS_QOPATCH.OPATCH_COMPARE_NODES (
   node     IN VARCHAR2 DEFAULT NULL,
   inst     IN VARCHAR2 DEFAULT NULL);
 RETURN VARCHAR2;
```

Parameters

Table 141-14 OPATCH_COMPARE_NODES Function Parameters

Parameter	Description
node	Node name
inst	Instance name

141.5.17 SET_CURRENT_OPINST Procedure

This procedure sets the node name and instance to get the inventory details specific to it in an Oracle Real Application Clusters (RAC) environment.

Syntax

```
DBMS_QOPATCH.SET_CURRENT_OPINST (
   node_name    IN VARCHAR2 DEFAULT NULL,
   inst_name    IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 141-15 SET_CURRENT_OPINST Procedure Parameters

Parameter	Description
node_name	Name of node
inst_name	Name of instance

142
DBMS_RANDOM

The DBMS_RANDOM package provides a built-in random number generator. DBMS_RANDOM is not intended for cryptography.

This chapter contains the following topics:

- Deprecated Subprograms
- Security Model
- Operational Notes
- Summary of DBMS_RANDOM Subprograms

142.1 DBMS_RANDOM Deprecated Subprograms

These subprograms are deprecated with Oracle Database 11*g*. Oracle recommends that you do not use deprecated procedures in new applications. Support for deprecated features is for backward compatibility only.

- INITIALIZE Procedure
- RANDOM Function
- TERMINATE Procedure

142.2 DBMS_RANDOM Security Model

This package should be installed as SYS. By default, the package is initialized with the current user name, current time down to the second, and the current session. Oracle recommends that users who need to execute this package should be given EXECUTE privilege explicitly and should not rely on PUBLIC EXECUTE privilege.

142.3 DBMS_RANDOM Operational Notes

These operational notes apply to DBMS_RANDOM.

- DBMS_RANDOM.RANDOM produces integers in [-2^^31, 2^^31).
- DBMS_RANDOM.VALUE produces numbers in [0,1) with 38 digits of precision.

DBMS_RANDOM can be explicitly initialized, but does not need to be initialized before calling the random number generator. It will automatically initialize with the date, user ID, and process ID if no explicit initialization is performed.

If this package is seeded twice with the same seed, then accessed in the same way, it will produce the same results in both cases.

In some cases, such as when testing, you may want the sequence of random numbers to be the same on every run. In that case, you seed the generator with a constant value by calling

one of the overloads of DBMS_RANDOM.SEED. To produce different output for every run, simply to omit the call to "Seed" and the system will choose a suitable seed for you.

142.4 Summary of DBMS_RANDOM Subprograms

This table lists the DBMS_RANDOM subprograms and briefly describes them.

Table 142-1 *DBMS_RANDOM Package Subprograms*

Subprogram	Description
INITIALIZE Procedure	Initializes the package with a seed value
NORMAL Function	Returns random numbers in a normal distribution
RANDOM Function	Generates a random number
SEED Procedures	Resets the seed
STRING Function	Gets a random string
TERMINATE Procedure	Terminates package
VALUE Functions	Gets a random number, greater than or equal to 0 and less than 1, with 38 digits to the right of the decimal (38-digit precision), while the overloaded function gets a random Oracle number x, where x is greater than or equal to low and less than high

142.4.1 INITIALIZE Procedure

This deprecated procedure initializes the generator.

> **Note:**
>
> This procedure is deprecated with Release 11gR1 and, although currently supported, it should not be used.

Syntax

```
DBMS_RANDOM.INITIALIZE (
   val  IN  BINARY_INTEGER);
```

Pragmas

```
PRAGMA restrict_references (initialize, WNDS);
```

Parameters

Table 142-2 INITIALIZE Procedure Parameters

Parameter	Description
val	Seed number used to generate a random number

Usage Notes

This procedure is obsolete as it simply calls the SEED Procedures.

142.4.2 NORMAL Function

This function returns random numbers in a standard normal distribution.

Syntax

```
DBMS_RANDOM.NORMAL
  RETURN NUMBER;
```

Pragmas

```
PRAGMA restrict_references (normal, WNDS);
```

Return Values

Table 142-3 NORMAL Function Parameters

Parameter	Description
number	Returns a random number

142.4.3 RANDOM Function

This deprecated procedure generates a random number.

> **Note:**
>
> This function is deprecated with Release 11gR1 and, although currently supported, it should not be used.

Syntax

```
DBMS_RANDOM.RANDOM
   RETURN binary_integer;
```

Pragmas

```
PRAGMA restrict_references (random, WNDS);
```

Return Values

Table 142-4 RANDOM Function Parameters

Parameter	Description
binary_integer	Returns a random integer greater or equal to -power(2,31) and less than power(2,31)

142.4.4 SEED Procedures

This procedure resets the seed.

Syntax

```
DBMS_RANDOM.SEED (
   val  IN  BINARY_INTEGER);

DBMS_RANDOM.SEED (
   val  IN  VARCHAR2);
```

Pragmas

```
PRAGMA restrict_references (seed, WNDS);
```

Parameters

Table 142-5 SEED Procedure Parameters

Parameter	Description
`val`	Seed number or string used to generate a random number

Usage Notes

The seed can be a string up to length 2000.

142.4.5 STRING Function

This function gets a random string.

Syntax

```
DBMS_RANDOM.STRING
   opt  IN  CHAR,
   len  IN  NUMBER)
  RETURN VARCHAR2;
```

Pragmas

```
PRAGMA restrict_references (string, WNDS);
```

Parameters

Table 142-6 STRING Function Parameters

Parameter	Description
opt	Specifies what the returning string looks like: • 'u', 'U' - returning string in uppercase alpha characters • 'l', 'L' - returning string in lowercase alpha characters • 'a', 'A' - returning string in mixed case alpha characters • 'x', 'X' - returning string in uppercase alpha-numeric characters • 'p', 'P' - returning string in any printable characters. Otherwise the returning string is in uppercase alpha characters.
len	Length of the returning string

Return Values

Table 142-7 STRING Function Return Values

Parameter	Description
VARCHAR2	Returns a VARCHAR2

142.4.6 TERMINATE Procedure

When you are finished with the package, call the TERMINATE procedure.

> **Note:**
>
> This procedure is deprecated with Release 11gR1 and, although currently supported, it should not be used.

Syntax

```
DBMS_RANDOM.TERMINATE;
```

142.4.7 VALUE Functions

The basic function gets a random number, greater than or equal to 0 and less than 1, with 38 digits to the right of the decimal (38-digit precision). Alternatively, you can get a random Oracle number x, where x is greater than or equal to low and less than high.

Syntax

```
DBMS_RANDOM.VALUE
  RETURN NUMBER;

DBMS_RANDOM.VALUE(
  low  IN  NUMBER,
  high IN  NUMBER)
RETURN NUMBER;
```

Parameters

Table 142-8 VALUE Function Parameters

Parameter	Description
`low`	Lowest number in a range from which to generate a random number. The number generated may be equal to `low`
`high`	Highest number below which to generate a random number. The number generated will be less than `high`

Return Values

Table 142-9 VALUE Function Return Values

Parameter	Description
`NUMBER`	Returns an Oracle Number

143
DBMS_REDACT

The DBMS_REDACT package provides an interface to Oracle Data Redaction, which enables you to mask (redact) data that is returned from queries issued by low-privileged users or an application.

This chapter contains the following topics:

- Overview
- Security Model
- Constants
- Operating Procedures
- Summary of DBMS_REDACT Subprograms

> **See Also:**
>
> - *Oracle Database Advanced Security Guide* regarding using Data Redaction to protect sensitive data

143.1 DBMS_REDACT Overview

Data redaction provides a way to define masking policies for an application. Oracle Data Redaction provides functionality to mask (redact) data that is returned from user SELECT queries in an application. The masking takes place in real time. The Data Redaction policy applies to the querying user, depending on this user's SYS_CONTEXT or XS_SYS_CONTEXT values. This redaction process does not require that the queried data be static or unchanging, or for the entire data set to be redacted at one time in an off-line manner. Oracle Database redacts only the data for the rows specified by the user's query, not the data for the entire column. The redaction takes place immediately before the data is returned to the querying user or application.

143.2 DBMS_REDACT Security Model

If the querying user has the EXEMPT REDACTION POLICY system privilege, redaction will not be performed. If the user does not have the EXEMPT REDACTION POLICY system privilege, the policy expression will be evaluated in the current user's environment. If the policy expression evaluates to TRUE, then redaction will be performed, otherwise no redaction will be performed.

You must have the EXECUTE privilege on the DBMS_REDACT package in order to execute its subprograms. Procedures in the interface are executed with privileges of the current user.

In addition to the EXECUTE privilege on the DBMS_REDACT package to execute its subprograms, you must have the following privileges:

- The CREATE TABLE or CREATE ANY TABLE privilege when the data redaction policy is on an object in your own schema. This requirement applies to the following procedures:
  - DBMS_REDACT.ADD_POLICY
  - DBMS_REDACT.DROP_POLICY
  - DBMS_REDACT.ALTER_POLICY
  - DBMS_REDACT.DISABLE_POLICY
  - DBMS_REDACT.ENABLE_POLICY
  - DBMS_REDACT.APPLY_POLICY_EXPR_TO_COL
- The CREATE ANY TABLE privilege when the data redaction policy is on an object in another user's schema. This requirement applies to the following procedures:
  - DBMS_REDACT.UPDATE_FULL_REDACTION_VALUES
  - DBMS_REDACT.CREATE_POLICY_EXPRESSION
  - DBMS_REDACT.DROP_POLICY_EXPRESSION
  - DBMS_REDACT.UPDATE_POLICY_EXPRESSION

143.3 DBMS_REDACT Constants

The DBMS_REDACT package defines several constants for specifying parameter values.

Table 143-1 Values for function_type Parameter of DBMS_REDACT.ADD_POLICY

Constant	Value	Type	Description
NONE	0	BINARY_INTEGER	No redaction
FULL	1	BINARY_INTEGER	Redact to fixed values
NULLIFY	6	BINARY_INTEGER	Returns a null value as a redacted value
PARTIAL	2	BINARY_INTEGER	Partial redaction, redact a portion of the column data
RANDOM	4	BINARY_INTEGER	Random redaction, each query results in a different random value
REGEXP	5	BINARY_INTEGER	Regular expression based redaction
REGEXP_WIDTH	7	BINARY_INTEGER	Regular expression based redaction that preserves the width of a column that uses a regular expression; designed for applications use the OCI_ATTR_CHAR_SIZE attribute of the Oracle OLE DB Provider interface

Table 143-2 Values for action Parameter of DBMS_REDACT.ALTER_POLICY

Constant	Value	Type	Description
ADD_COLUMN	1	BINARY_INTEGER	Add a column to the redaction policy
DROP_COLUMN	2	BINARY_INTEGER	Drop a column from the redaction policy
MODIFY_EXPRESSION	3	BINARY_INTEGER	Modify the expression of a redaction policy (the expression evaluates to a BOOLEAN value: if TRUE then redaction is applied, otherwise not)
MODIFY_COLUMN	4	BINARY_INTEGER	Modify a column in the redaction policy to change the redaction function_type or the function_parameters
SET_POLICY_DESCRIPTION	5	BINARY_INTEGER	Set a description for the redaction policy
SET_COLUMN_DESCRIPTION	6	BINARY_INTEGER	Set a description for the redaction performed on the column

143.4 DBMS_REDACT Operating Procedures

The following table presents the relationship between the type of redaction function and its parameters, based on the datatype of the column being redacted. Examples of the various format strings are provided, showing how to perform some commonplace redaction for a string datatype (in this case, a Social Security Number (SSN)), a DATE datatype, and various examples of redaction for the number datatype.

Table 143-3 Data Redaction Function Types

function_type	function_parameters	Examples
DBMS_REDACT.NONE	-	-
DBMS_REDACT.FULL	-	-
DBMS_REDACT.PARTIAL (for character types)	A comma-separated list, containing the following five fields (with no spaces after the commas delimiting the fields): • REDACT_PARTIAL_INPUT_FORMAT • REDACT_PARTIAL_OUTPUT_FORMAT • REDACT_PARTIAL_MASKCHAR • REDACT_PARTIAL_MASKFROM • REDACT_PARTIAL_MASKTO See Table 143-4.	'VVVFVVFVVVV,VVV-VV-VVVV,X,1,5' for masking the first 5 digits of SSN strings like 123-45-6789, adding dashes back to format it, resulting in strings like XXX-XX-6789 'VVVFVVFVVVV,VVV VV VVVV,X,1,5' for masking the first 5 digits of SSN strings like 123-45-6789, adding spaces to format it, resulting in strings like XXX XX 6789

Table 143-3 (Cont.) Data Redaction Function Types

function_type	function_parameters	Examples
DBMS_REDACT.PARTIAL (for character types), continued	REDACT_PARTIAL_INPUT_FORMAT - the input format: V for value to be possibly redacted, F for formatting character to be ignored	The REDACT_PARTIAL_INPUT_FORMAT field value VVVFVVFVVVV for matching SSN strings like 123-45-6789
DBMS_REDACT.PARTIAL (for character types), continued	REDACT_PARTIAL_OUTPUT_FORMAT - the output format: V for output of redaction. Any other character will be treated as a formatting character and output literally.	The REDACT_PARTIAL_OUTPUT_FORMATfield value VVV-VV-VVVV can be used to redact SSN strings into XXX-XX-6789 (X comes from REDACT_PARTIAL_MASKCHAR field).
DBMS_REDACT.PARTIAL (for character types), continued	REDACT_PARTIAL_MASKCHAR - the character used to redact the input	The value X for redacting SSN strings into XXX-XX-6789.
DBMS_REDACT.PARTIAL (for character types), continued	REDACT_PARTIAL_MASKFROM - specifies which V within the REDACT_PARTIAL_INPUT_FORMAT from which to start the redaction (see explanation following the next entry, REDACT_PARTIAL_MASKTO)	The value 1 for redacting SSN strings starting at the first V of REDACT_PARTIAL_INPUT_FORMAT of VVVFVVFVVVV into strings like XXX-XX-6789
DBMS_REDACT.PARTIAL (for character types), continued	REDACT_PARTIAL_MASKTO - specifies which V within the REDACT_PARTIAL_INPUT_FORMAT at which to end the redaction	The value 5 for redacting SSN strings up to and including the fifth V within REDACT_PARTIAL_INPUT_FORMAT of VVVFVVFVVVV into strings like XXX-XX-6789. Note how the format character '-' (corresponding to the first F within REDACT_PARTIAL_INPUT_FORMAT) is ignored as far as redaction is concerned, so the value here is 5 as opposed to 6.

Table 143-3 (Cont.) Data Redaction Function Types

function_type	function_parameters	Examples
DBMS_REDACT.PARTIAL (for character types), continued	The REDACT_PARTIAL_MASKFROM and REDACT_PARTIAL_MASKTO field values are specified as counts of the number of V characters in the REDACT_PARTIAL_INPUT_FORMAT field, up to and including the intended position, starting from the leftmost V. This way, REDACT_PARTIAL_MASKFROM and REDACT_PARTIAL_MASKTO are independent of the specific formatting of the data. For example, in the common use case of masking an SSN to show only the last four digits, data like 123456789 (with REDACT_PARTIAL_INPUT_FORMAT of VVVVVVVVV) and data like 123-45-6789 (with REDACT_PARTIAL_INPUT_FORMAT of VVVFVVFVVVV), would both use REDACT_PARTIAL_MASKFROM of 1 and REDACT_PARTIAL_MASKTO of 5.	-
DBMS_REDACT.PARTIAL (for number types)	A comma-separated list, containing the following three fields (with no spaces after the commas delimiting the fields): • REDACT_PARTIAL_MASKCHAR • REDACT_PARTIAL_MASKFROM • REDACT_PARTIAL_MASKTO See Table 143-4.	'9,1,5' for redacting the first 5 digits of an SSN number 123456789 into 999996789; or '0,1,2' for redacting a number 1.23 to 0.03.
DBMS_REDACT.PARTIAL (for number types), continued	REDACT_PARTIAL_MASKCHAR - the character used to redact the input, in the range between 0 and 9 REDACT_PARTIAL_MASKFROM - the position, starting from 1, from which to start the redaction. The position does not include the decimal point if it is present. REDACT_PARTIAL_MASKTO - the position at which to end the redaction	-

Table 143-3 (Cont.) Data Redaction Function Types

function_type	function_parameters	Examples
DBMS_REDACT.PARTIAL (for datetime datatypes)	A list, containing the following five fields (concatenated so that there is no space between the fields): • REDACT_PARTIAL_DATE_MONTH • REDACT_PARTIAL_DATE_DAY • REDACT_PARTIAL_DATE_YEAR • REDACT_PARTIAL_DATE_HOUR • REDACT_PARTIAL_DATE_MINUTE • REDACT_PARTIAL_DATE_SECOND See Table 143-4.	'm12DYHMS', which changes 01-May-01 01:01:01 to 01-Dec-01 01:01:01.
DBMS_REDACT.PARTIAL (for datetime datatypes), continued	REDACT_PARTIAL_DATE_MONTH: 'M' (no masking of month) or 'm#' (mask month to a specific month, if possible), where # (the month specified by its number) is between 1 and 12 REDACT_PARTIAL_DATE_DAY: 'D' (no masking of date) or 'd#' (mask day to #, if possible), # between 1 and 31 REDACT_PARTIAL_DATE_YEAR: 'Y' (no masking of year) or 'y#' (mask year to #, if possible), # between 1 and 9999 REDACT_PARTIAL_DATE_HOUR: 'H' (no masking of hour) or 'h#' (mask hour to #, if possible), # between 0 and 23 REDACT_PARTIAL_DATE_MINUTE: 'M' (no masking of minute) or 'm#' (mask minute to #, if possible), # between 0 and 59 REDACT_PARTIAL_DATE_SECOND: 'S' (no masking of second) or 's#' (mask second to #, if possible), # between 0 and 59	-
DBMS_REDACT.PARTIAL_WIDTH	Same as DBMS_REDACT.PARTIAL	-
DBMS_REDACT.RANDOM	-	-

Table 143-4 Format Descriptors with Component Field Names and Delimiters

Datatype	Format Descriptor for Partial redaction
Character	`REDACT_PARTIAL_INPUT_FORMAT || ',' || REDACT_PARTIAL_OUTPUT_FORMAT || ',' || REDACT_PARTIAL_MASKCHAR || ',' || REDACT_PARTIAL_MASKFROM || ',' || REDACT_PARTIAL_MASKTO`
Number	`REDACT_PARTIAL_MASKCHAR || ',' || REDACT_PARTIAL_MASKFROM || ',' || REDACT_PARTIAL_MASKTO`
Datetime	`REDACT_PARTIAL_DATE_MONTH || REDACT_PARTIAL_DATE_DAY || REDACT_PARTIAL_DATE_YEAR || REDACT_PARTIAL_DATE_HOUR || REDACT_PARTIAL_DATE_MINUTE || REDACT_PARTIAL_DATE_SECOND`

143.5 Summary of DBMS_REDACT Subprograms

This table lists and briefly describes the `DBMS_REDACT` package subprograms.

Table 143-5 DBMS_REDACT Package Subprograms

Subprogram	Description
ADD_POLICY Procedure	Defines a Data Redaction policy for a table or view
ALTER_POLICY Procedure	Alters a Data Redaction policy for a table or view
APPLY_POLICY_EXPR_TO_COL Procedure	Applies a Data Redaction policy expression to a redacted column
CREATE_POLICY_EXPRESSION Procedure	Creates a Data Redaction policy expression
DISABLE_POLICY Procedure	Disables a Data Redaction policy
DROP_POLICY Procedure	Drops a Data Redaction policy
DROP_POLICY_EXPRESSION Procedure	Drops a Data Redaction policy expression
ENABLE_POLICY Procedure	Enables a Data Redaction policy
UPDATE_FULL_REDACTION_VALUES Procedure	Modifies the default displayed values for a Data Redaction policy for full redaction
UPDATE_POLICY_EXPRESSION Procedure	Updates a Data Redaction policy expression

143.5.1 ADD_POLICY Procedure

This procedure defines a Data Redaction policy for a table or view.

Syntax

```
DBMS_REDACT.ADD_POLICY (
   object_schema                IN    VARCHAR2 := NULL,
   object_name                  IN    VARCHAR2,
```

```
policy_name                IN    VARCHAR2,
column_name                IN    VARCHAR2 := NULL,
function_type              IN    BINARY_INTEGER := DBMS_REDACT.FULL,
function_parameters        IN    VARCHAR2 := NULL,
expression                 IN    VARCHAR2,
enable                     IN    BOOLEAN := TRUE,
regexp_pattern             IN    VARCHAR2 := NULL,
regexp_replace_string      IN    VARCHAR2 := NULL,
regexp_position            IN    BINARY_INTEGER := 1,
regexp_occurrence          IN    BINARY_INTEGER := 0,
regexp_match_parameter     IN    VARCHAR2 := NULL,
policy_description         IN    VARCHAR2 := NULL,
column_description         IN    VARCHAR2 := NULL);
```

Parameters

Table 143-6 *ADD_POLICY Procedure Parameters*

Parameter	Description
`object_schema`	Schema owning the table, current user if `NULL`
`object_name`	Name of table or view to which to add a Data Redaction policy
`policy_name`	Name of policy
`column_name`	[Optional] Name of one column to which the redaction policy applies. If you must redact more than one column, use the ALTER_POLICY Procedure to add the additional columns.
`function_type`	Type of redaction function to use. Possible values are: - `DBMS_REDACT.NONE` - `DBMS_REDACT.FULL` (default) - `DBMS_REDACT.NULLIFY` - `DBMS_REDACT.PARTIAL` - `DBMS_REDACT.RANDOM` - `DBMS_REDACT.REGEXP` - `DBMS_REDACT.REGEXP_WIDTH` If the `function_type` is `DBMS_REDACT.REGEXP` or `DBMS_REDACT.REGEXP_WIDTH`, then you must omit the `function_parameters` parameter, and use the `regexp_*` parameters to define the Data Redaction policy. See Table 143-1 for an overview of the meanings of these values, and for some examples of their use.

Table 143-6 (Cont.) *ADD_POLICY Procedure Parameters*

Parameter	Description
`function_parameters`	Parameters to the redaction function. The possible values depend on the value of the `function_type` provided. If the `function_type` is `DBMS_REDACT.REGEXP` or `DBMS_REDACT.REGEXP_WIDTH`, then you must omit the `function_parameters` parameter, and use the `regexp_*` parameters to define the Data Redaction policy. - `DBMS_REDACT.NONE`: Can be omitted entirely and defaults to `NULL` - `DBMS_REDACT.FULL`: Can be omitted entirely and defaults to `NULL` - Masking parameters for partial character masking. For character datatypes, a comma-separated list containing these fields: • Input format: `'V'` for value to be possibly masked, `'F'` for formatting character to be ignored • Output format: `'V'` for output of masking, any other characters will be treated as formatting characters. • Mask character: a character that will be used to replace the actual values. Examples are `'*'` and `'x'`. • Starting digit position: specifies the starting (character) position to begin replacing actual values with the masking character. The beginning of the string is position 1. Positions do not include formatting characters. • Ending digit position: specifies the ending (character) position to end masking. An example is `'VVVFVVFVVVV,VVV-VV-VVVV,X,1,5'` for masking the first 5 digits of SSN string `123-45-6789`, and adding dashes back to format it like an SSN, resulting in `XXX-XX-6789`. For number datatypes, a comma-separated list containing these fields: • Mask character: this is a character between `'0'` to `'9'` that will be used to replace the actual values. • Starting digit position: specifies the starting (digit) position to begin replacing actual values with the masking character. The beginning of the string is position 1. Positions do not include the decimal point. • Ending digit position: this specifies the ending digit position to end masking. An example is `'9,1,5'` for masking the first 5 digits of a Social Security number number `123456789`, resulting in `999996789`. For datetime datatypes, the format is a packed string (no spaces or commas) containing the following sequence of fields. Please note that each field can consist of one or more characters, and the field length depends on whether masking is required. The one-character fields are used to specify that no redaction of that component of the datetime value is to take place. The longer fields indicate a specific time or date to use as the redacted value of that component of the datetime value.

Table 143-6 (Cont.) *ADD_POLICY Procedure Parameters*

Parameter	Description
	• Month: 'M' (no masking of month) or 'm#' (mask month to a specific month, if possible), where # (the month specified by its number) is between 1 and 12 • Day: 'D' (no masking of date) or 'd#' (mask day to #, if possible), # between 1 and 31 • Year: 'Y' (no masking of year) or 'y#' (mask year to #, if possible), # between 1 and 9999 • Hour: 'H' (no masking of hour) or 'h#' (mask hour to #, if possible), # between 0 and 23 • Minute: 'M' (no masking of minute) or 'm#' (mask minute to #, if possible), # between 0 and 59 • Second: 'S' (no masking of second) or 's#' (mask second to #, if possible), # between 0 and 59 An example is 'm12dyhs', which changes 02-May-13 12:30:23 to 01-Dec-01 01:01:01 For partial character and number-masking shortcuts, see *Oracle Database Advanced Security Guide*.
expression	Default boolean expression for the table or view. If this expression is used, then redaction takes place only if this policy expression evaluates to TRUE. See The following functions are supported: • SYS_CONTEXT • XS_SYS_CONTEXT • SUBSTR functions (includes SUBSTRB, SUBSTRC, SUBSTR2, SUBSTR4) • LENGTH functions (includes LENGTHB, LENGTHC, LENGTH2, LENGTH4) • V (APEX_UTIL.GET_SESSION_STATE) • NV (APEX_UTIL.GET_NUMERIC_SESSION_STATE) • OLS_LABEL_DOMINATES • DOMINATES • OLS_DOMINATES • OLS_DOM • DOM • OLS_STRICTLY_DOMINATES • STRICTLY_DOMINATES • S_DOM • SA_UTL.DOMINATES • SA_UTL.CHECK_READ • SA_UTL.NUMERIC_LABEL • CHAR_TO_LABEL • SA_SESSION.LABEL See *Oracle Database Advanced Security Guide* for more information about these supported functions

Table 143-6 (Cont.) *ADD_POLICY Procedure Parameters*

Parameter	Description
`enable`	Boolean value that determines whether the Data Redaction policy is enabled on creation. The default value is `TRUE`, which means that the policy is automatically enabled upon creation. If the `enable` parameter is set to `FALSE`, the policy takes effect only when it is subsequently enabled by calling the `DBMS_REDACT.ENABLE_POLICY` procedure.
`regexp_pattern`	Regular expression pattern up to 512 bytes. Use only if the `function_type` parameter is `DBMS_REDACT.REGEXP`. Also, do not specify the `function_parameters` parameter when `function_type` is `DBMS_REDACT.REGEXP`. See *Oracle Database SQL Language Reference* for more information and examples on using regular expression patterns.
`regexp_replace_string`	Replacement string (up to 4000 characters in length) with up to 500 back-references to subexpressions in the form `\n`, where `n` is a number between 1 and 9. Use only if the `function_type` parameter is `DBMS_REDACT.REGEXP`
`regexp_position`	Integer counting from 1, specifies the position where the search must begin. Use only if the `function_type` parameter is `DBMS_REDACT.REGEXP`
`regexp_occurrence`	• Use 0 to replace all occurrences of the match • Use positive integer *n* to replace the *n*-th occurence of the match. Use only if the `function_type` parameter is `DBMS_REDACT.REGEXP`
`regexp_match_parameter`	Changes the default matching behavior, possible values are a combination of 'i', 'c', 'n', 'm', 'x' Use only if the `function_type` parameter is `DBMS_REDACT.REGEXP` See *Oracle Database SQL Language Reference* for more information and examples on using regular expression match parameters.
`policy_description`	Description of redaction policy
`column_description`	Description of the column being redacted

Exceptions

- `ORA-28060` - A Data Redaction policy already exists on this column.
- `ORA-28061` - This object cannot have a Data Redaction policy defined on it.
- `ORA-28062` - The policy expression is too long.
- `ORA-28063` - The policy expression is empty.
- `ORA-28064` - The type of redaction function is not valid.

- ORA-28066 - Invalid column *column*
- ORA-28069 - A Data Redaction policy already exists on this object.
- ORA-28073 - The column *column_name* has an unsupported datatype.
- ORA-28074 - The field *field_name* of the masking parameters is not valid

  The field can be any of the following:

  - REDACT_PARTIAL_INPUT_FORMAT
  - REDACT_PARTIAL_OUTPUT_FORMAT
  - REDACT_PARTIAL_MASKCHAR
  - REDACT_PARTIAL_MASKFROM
  - REDACT_PARTIAL_MASKTO
  - REDACT_PARTIAL_DATE_MONTH
  - REDACT_PARTIAL_DATE_DAY
  - REDACT_PARTIAL_DATE_YEAR
  - REDACT_PARTIAL_DATE_HOUR
  - REDACT_PARTIAL_DATE_MINUTE
  - REDACT_PARTIAL_DATE_SECOND

  See Table 143-3 and Table 143-4 for examples of the field contents and field ordering.
- ORA-28075 - The policy expression has unsupported functions
- ORA-28076 - An attribute was not specified for SYS_SESSION_ROLES
- ORA-28077 - The attribute specified (*attribute*) exceeds the maximum length
- ORA-28078 - A regular expression parameter is missing or invalid
- ORA-28082 - The parameter *parameter* is invalid (where the possible values are function_parameters, column_description , policy_name and policy_description)
- ORA-28085 - The input and output lengths of the redaction do not match.

Usage Notes

See DBMS_REDACT Security Model for a list of the required privileges for this procedure.

See Operating Procedures for more information regarding function types and function parameters with related examples.

A named Data Redaction policy expression that has been applied to a redacted column takes precedence over the expression defined in the expression parameter. To find redacted columns that are affected by named policy expressions, query the REDACTION_EXPRESSIONS data dictionary view.

Example

Partial redaction policy:

```
BEGIN
   DBMS_REDACT.ADD_POLICY(
     object_schema        => 'hr',
     object_name          => 'employees',
     column_name          => 'employee_id',
     policy_name          => 'mask_emp_id_nums',
     function_type        => DBMS_REDACT.PARTIAL,
     function_parameters  => '7,1,5',
     expression           => '1=1');
END;
```

Full redaction policy:

```
BEGIN
   DBMS_REDACT.ADD_POLICY(
     object_schema        => 'hr',
     object_name          => 'employees',
     column_name          => 'employee_id',
     policy_name          => 'mask_emp_ids',
     function_type        => DBMS_REDACT.FULL,
     expression           => 'SYS_CONTEXT(''SYS_SESSION_ROLES'',''CLERK'')
                                                                  = ''FALSE''');
END;
```

143.5.2 ALTER_POLICY Procedure

This procedure alters an existing Data Redaction policy for a table or view.

It alters a the policy in one or more of the following ways:

- By changing the policy expression
- By changing the type of redaction for a specified column
- By changing the parameters to the redaction function for a specified column
- By adding a column to the redaction policy (the redaction type and any parameters must be specified).
- By removing a column from the redaction policy

Syntax

```
DBMS_REDACT.ALTER_POLICY (
   object_schema               IN    VARCHAR2 := NULL,
   object_name                 IN    VARCHAR2,
   policy_name                 IN    VARCHAR2,
   action                      IN    BINARY_INTEGER := DBMS_REDACT.ADD_COLUMN,
   column_name                 IN    VARCHAR2 := NULL,
   function_type               IN    BINARY_INTEGER := DBMS_REDACT.FULL,
   function_parameters         IN    VARCHAR2 := NULL,
   expression                  IN    VARCHAR2,
   regexp_pattern              IN    VARCHAR2 := NULL,
   regexp_replace_string       IN    VARCHAR2 := NULL,
   regexp_position             IN    BINARY_INTEGER := 1,
   regexp_occurrence           IN    BINARY_INTEGER := 0,
   regexp_match_parameter      IN    VARCHAR2 := NULL,
   policy_description          IN    VARCHAR2 := NULL,
   column_description          IN    VARCHAR2 := NULL);
```

Parameters

Table 143-7 *ALTER_POLICY Procedure Parameters*

Parameter	Description
`object_schema`	Schema owning the table, current user if `NULL`
`object_name`	Name of table or view to which to alter a Data Redaction policy
`policy_name`	Name of policy limited to 30 bytes
`action`	Action to take. For more information see Table 143-2.
`column_name`	[Optional] Name of one column to which the redaction policy applies.
`function_type`	Type of redaction function to use. Possible values are: - `DBMS_REDACT.NONE` - `DBMS_REDACT.FULL` (default) - `DBMS_REDACT.NULLIY` - `DBMS_REDACT.PARTIAL` - `DBMS_REDACT.RANDOM` - `DBMS_REDACT.REGEXP` - `DBMS_REDACT.REGEXP_WIDTH` If the `function_type` is `DBMS_REDACT.REGEXP` or `DBMS_REDACT.REGEXP_WIDTH`, then you must omit the `function_parameters` parameter, and use the `regexp_pattern`, `regexp_replace_string`, `regexp_position`, `regexp_occurrence`, and `regexp_match_parameter` to define the Data Redaction policy. See Table 143-1 for an overview of the meanings of these values, and for some examples of their use.

Table 143-7 (Cont.) *ALTER_POLICY Procedure Parameters*

Parameter	Description
function_parameters	Parameters to the redaction function. The possible values depend on the value of the function_type provided. If the function_type is DBMS_REDACT.REGEXP or DBMS_REDACT.REGEXP_WIDTH, then you must omit the function_parameters parameter, and use the regexp_pattern, regexp_replace_string, regexp_position, regexp_occurrence, and regexp_match_parameter to define the Data Redaction policy. - If the function_type is DBMS_REDACT.NONE, the function_parameters parameter can be omitted entirely and defaults to NULL. - If the function_type is DBMS_REDACT.FULL, the function_parameters parameter can be omitted entirely and defaults to NULL. - If the function_type is DBMS_REDACT.PARTIAL, the function_parameters parameter represents the masking parameters for partial masking. • Input format: 'V' for value to be possibly masked, 'F' for formatting character to be ignored • Output format: 'V' for output of masking, any other characters will be treated as formatting characters. • Mask character: a character that will be used to replace the actual values. Examples are '*' and 'x'. • Starting digit position: specifies the starting (character) position to begin replacing actual values with the masking character. The beginning of the string is position 1. Positions do not include formatting characters. • Ending digit position: specifies the ending (character) position to end masking. An example is 'VVVFVVFVVVV,VVV-VV-VVVV,X,1,5' for masking the first 5 digits of SSN string 123-45-6789, and adding dashes back to format it like an SSN, resulting in XXX-XX-6789. For number datatypes, a comma-separated list containing these fields: • Mask character: this is a character between '0' to '9' that will be used to replace the actual values. • Starting digit position: specifies the starting (digit) position to begin replacing actual values with the masking character. The beginning of the string is position 1. Positions do not include the decimal point. • Ending digit position: this specifies the ending digit position to end masking. An example is '9,1,5' for masking the first 5 digits of a Social Security number number 123456789, resulting in 999996789. For datetime datatypes, the format is a packed string (no spaces or commas) containing the following sequence of fields. Please note that each field can consist of one or more characters, and the field length depends on whether masking is required. The one-character fields are used to specify that no redaction of that component of the datetime value is to take

Table 143-7 (Cont.) *ALTER_POLICY Procedure Parameters*

Parameter	Description
	place. The longer fields indicate a specific time or date to use as the redacted value of that component of the datetime value. • Month: `'M'` (no masking of month) or `'m#'` (mask month to a specific month, if possible), where # (the month specified by its number) is between 1 and 12 • Day: `'D'` (no masking of date) or `'d#'` (mask day to #, if possible), # between 1 and 31 • Year: `'Y'` (no masking of year) or `'y#'` (mask year to #, if possible), # between 1 and 9999 • Hour: `'H'` (no masking of hour) or `'h#'` (mask hour to #, if possible), # between 0 and 23 • Minute: `'M'` (no masking of minute) or `'m#'` (mask minute to #, if possible), # between 0 and 59 • Second: `'S'` (no masking of second) or `'s#'` (mask second to #, if possible), # between 0 and 59 An example is `'m12DYHMS'`, which changes `01-May-01 01:01:01` to `01-Dec-01 01:01:01` For partial character and number-masking shortcuts, see *Oracle Database Advanced Security Guide*.
`expression`	Default boolean expression for the table or view. If this expression is used, then redaction takes place only if this policy expression evaluates to `TRUE`. The following functions are supported: • `SYS_CONTEXT` • `NV` (`APEX_UTIL.GET_NUMERIC_SESSION_STATE`) • `V` (`APEX_UTIL.GET_SESSION_STATE`) • `OLS_LABEL_DOMINATES` • `DOMINATES` • `OLS_DOMINATES` • `OLS_DOM` • `DOM` • `OLS_STRICTLY_DOMINATES` • `STRICTLY_DOMINATES` • `S_DOM` • `SA_UTL.DOMINATES` • `SA_UTL.CHECK_READ` • `SA_UTL.NUMERIC_LABEL` • `CHAR_TO_LABEL` • `SA_SESSION.LABEL`
`regexp_pattern`	Regular expression pattern up to 512 bytes. Use only if the `function_type` parameter is `DBMS_REDACT.REGEXP`. Also, do not specify the `function_parameters` parameter when `function_type` is `DBMS_REDACT.REGEXP`. See *Oracle Database SQL Language Reference* for more information and examples on using regular expression patterns

Table 143-7 (Cont.) *ALTER_POLICY Procedure Parameters*

Parameter	Description
`regexp_replace_string`	Replacement string (up to 4000 characters in length) with up to 500 back-references to subexpressions in the form `\n`, where `n` is a number between 1 and 9. Use only if the `function_type` parameter is `DBMS_REDACT.REGEXP`
`regexp_position`	Integer counting from 1, specifies the position where the search must begin. Use only if the `function_type` parameter is `DBMS_REDACT.REGEXP`
`regexp_occurrence`	• Use 0 to replace all occurrences of the match • Use positive integer *n* to replace the *n*-th occurence of the match. Use only if the `function_type` parameter is `DBMS_REDACT.REGEXP`
`regexp_match_parameter`	Changes the default matching behavior, possible values are a combination of 'i', 'c', 'n', 'm', 'x' Use only if the `function_type` parameter is `DBMS_REDACT.REGEXP` See *Oracle Database SQL Language Reference* for more information and examples on using regular expression match parameters.
`policy_description`	Description of redaction policy
`column_description`	Description of the column being redacted

Exceptions

- `ORA-28062` - The policy expression is too long.
- `ORA-28063` - The policy expression is empty.
- `ORA-28064` - The type of redaction function is not valid.
- `ORA-28066` - Invalid column *`column`*
- `ORA-28067` - Missing or invalid column name
- `ORA-28068` - The object *`object`* does not have a Data Redaction policy.
- `ORA-28070` - The column *`column`* does not have a Data Redaction policy.
- `ORA-28071` - The action is not valid.
- `ORA-28072` - The specified policy name is incorrect.
- `ORA-28073` - The column *`column_name`* has an unsupported datatype.
- `ORA-28074` - The field *`field_name`* of the masking parameters is not valid

  The field can be any of the following:

  - `REDACT_PARTIAL_INPUT_FORMAT`
  - `REDACT_PARTIAL_OUTPUT_FORMAT`
  - `REDACT_PARTIAL_MASKCHAR`

  - REDACT_PARTIAL_MASKFROM
  - REDACT_PARTIAL_MASKTO
  - REDACT_PARTIAL_DATE_MONTH
  - REDACT_PARTIAL_DATE_DAY
  - REDACT_PARTIAL_DATE_YEAR
  - REDACT_PARTIAL_DATE_HOUR
  - REDACT_PARTIAL_DATE_MINUTE
  - REDACT_PARTIAL_DATE_SECOND

  See Table 143-3 and Table 143-4 for examples of the field contents and field ordering.

- ORA-28075 - The policy expression has unsupported functions.
- ORA-28076 - An attribute was not specified for SYS_SESSION_ROLES.
- ORA-28077 - The attribute specified (*attribute*) exceeds the maximum length.
- ORA-28078 - A regular expression parameter is missing or invalid.
- ORA-28082 - The parameter *parameter* is invalid (where the possible values are function_parameters, column_description, policy_name and policy_description)
- ORA-28085 - The input and output lengths of the redaction do not match.

Usage Notes

See DBMS_REDACT Security Model for a list of the required privileges for this procedure.

See Operating Procedures for more information regarding Function Types and Function Parameters with related examples.

A named Data Redaction policy expression that has been applied to a redacted column takes precedence over the expression defined in the expression parameter. To find redacted columns that are affected by named policy expressions, query the REDACTION_EXPRESSIONS data dictionary view.

Examples

```
BEGIN
   DBMS_REDACT.ALTER_POLICY(
     object_schema          => 'HR',
     object_name            => 'EMPLOYEES',
     policy_name            => 'mask_emp_id_nums',
     action                 => DBMS_REDACT.DROP_COLUMN,
     column_name            => 'EMAIL');
END;
```

143.5.3 APPLY_POLICY_EXPR_TO_COL Procedure

This procedure associates a named Oracle Data Redaction policy expression with a redacted column from a table or view.

Syntax

```
DBMS_REDACT.APPLY_POLICY_EXPR_TO_COL (
   object_schema               IN VARCHAR2 := NULL,
   object_name                 IN VARCHAR2,
   column_name                 IN VARCHAR2,
   policy_expression_name      IN VARCHAR2 := NULL);
```

Parameters

Table 143-8 *APPLY_POLICY_EXPR_TO_COL Procedure Parameters*

Parameter	Description
`object_schema`	Name of the schema that contains the redacted column
`object_name`	Name of the object (table or view) that contains the redacted column
`column_name`	Name of the redacted column to which the policy expression is applied
`policy_expression_name`	Name of the policy expression

Exceptions

- `ORA-28068` - The object *object* does not have a Data Redaction policy.
- `ORA-28082` - The parameter *parameter* is invalid.
- `ORA-28092` - The parameter *parameter* with value *value* has an error.

Usage Notes

See DBMS_REDACT Security Model for a list of the required privileges for this procedure.

You can find existing Data Redaction policy expressions by querying the `REDACTION_EXPRESSIONS` data dictionary view. To find columns that have been redacted, query the `REDACTION_COLUMNS` data dictionary view.

Example

```
BEGIN
   DBMS_REDACT.APPLY_POLICY_EXPR_TO_COL(
      object_schema           => 'OE',
      object_name             => 'CUSTOMERS',
      column_name             => 'INCOME_LEVEL',
      policy_expression_name  => 'oe_redact_pol');
END;
```

143.5.4 CREATE_POLICY_EXPRESSION Procedure

This procedure creates a named Oracle Data Redaction policy expression.

Syntax

```
DBMS_REDACT.CREATE_POLICY_EXPRESSION (
   policy_expression_name          IN    VARCHAR2,
   expression                      IN    VARCHAR2,
   policy_expression_description   IN    VARCHAR2 := NULL);
```

Parameters

Table 143-9 *CREATE_POLICY_EXPRESSION Procedure Parameters*

Parameter	Description
`policy_expression_name`	Name of the policy expression
`expression`	Definition of the policy expression
`policy_expression_description`	Description of the policy expression

Exceptions

- `ORA-28082` - The parameter *parameter* is invalid.
- `ORA-28092` - The parameter *parameter* with value *value* has an error.

Usage Notes

See DBMS_REDACT Security Model for a list of the required privileges for this procedure.

See Operating Procedures for more information regarding function types and function parameters with related examples.

After you create a policy expression, you can associate it with a redacted table or view column by running the `DBMS_REDACT.APPLY_POLICY_EXPR_TO_COL` procedure. To find existing redacted columns, query the `REDACTION_COLUMNS` data dictionary view.

Example

```
BEGIN
   DBMS_REDACT.CREATE_POLICY_EXPRESSION(
     policy_expression_name          => 'oe_redact_pol',
     expression                      =>
'SYS_CONTEXT(''USERENV'',''SESSION_USER'') = ''OE''''),
     policy_expression_description   => 'Enables policy for user OE ');
END;
```

143.5.5 DISABLE_POLICY Procedure

This procedure disables a Data Redaction policy.

Syntax

```
DBMS_REDACT.DISABLE_POLICY (
   object_schema               IN    VARCHAR2 := NULL,
   object_name                 IN    VARCHAR2,
   policy_name                 IN    VARCHAR2);
```

Parameters

Table 143-10 *DISABLE_POLICY Procedure Parameters*

Parameter	Description
`object_schema`	Schema owning the table or view, current user if `NULL`
`object_name`	Name of table or view for which to disable a Data Redaction policy
`policy_name`	Name of policy to be disabled

Exceptions

- `ORA-28068` - The object *`object`* does not have a Data Redaction policy.
- `ORA-28072` - The specified policy name is incorrect.
- `ORA-28080` - The policy was already disabled.

Usage Notes

See DBMS_REDACT Security Model for a list of the required privileges for this procedure.

Examples

```
BEGIN
   DBMS_REDACT.DISABLE_POLICY (
     object_schema    => 'hr',
     object_name      => 'employees',
     policy_name      => 'mask_emp_ids');
END;
```

143.5.6 DROP_POLICY Procedure

This procedure drops a Data Redaction policy by removing a masking policy from the table or view.

Syntax

```
DBMS_REDACT.DROP_POLICY (
   object_schema               IN    VARCHAR2 := NULL,
   object_name                 IN    VARCHAR2,
   policy_name                 IN    VARCHAR2);
```

Parameters

Table 143-11 *DROP_POLICY Procedure Parameters*

Parameter	Description
`object_schema`	Schema owning the table or view, current user if `NULL`
`object_name`	Name of table or view from which to drop a Data Redaction policy
`policy_name`	Name of policy to be dropped

Exceptions

- `ORA-28068` - The object *`object`* does not have a Data Redaction policy.
- `ORA-28072` - The specified policy name is incorrect.

Usage Notes

See DBMS_REDACT Security Model for a list of the required privileges for this procedure.

Examples

```
BEGIN
   DBMS_REDACT.DROP_POLICY (
      object_schema    =>  'hr',
      object_name      =>  'employees',
      policy_name      =>  'mask_emp_ids');
END;
```

143.5.7 DROP_POLICY_EXPRESSION Procedure

This procedure drops a named policy expression.

Syntax

```
DBMS_REDACT.DROP_POLICY_EXPRESSION (
   policy_expression_name       IN    VARCHAR2);
```

Parameters

Table 143-12 *DROP_POLICY_EXPRESSION Procedure Parameters*

Parameter	Description
`policy_expression_name`	Name of the policy expression

Exceptions

- `ORA-28082` - The parameter *parameter* is invalid.
- `ORA-28092` - The parameter *parameter* with value *value* has an error.

Usage Notes

See DBMS_REDACT Security Model for a list of the required privileges for this procedure.

You can find existing Data Redaction policy expressions by querying the `REDACTION_EXPRESSIONS` data dictionary view.

Example

```
BEGIN
   DBMS_REDACT.DROP_POLICY_EXPRESSION(
     policy_expression_name  => 'oe_redact_pol');
END;
```

143.5.8 ENABLE_POLICY Procedure

This procedure re-enables a Data Redaction policy.

Syntax

```
DBMS_REDACT.ENABLE_POLICY (
   object_schema               IN    VARCHAR2 := NULL,
   object_name                 IN    VARCHAR2,
   policy_name                 IN    VARCHAR2);
```

Parameters

Table 143-13 ***ENABLE_POLICY Procedure Parameters***

Parameter	Description
`object_schema`	Schema owning the table or view, current user if `NULL`
`object_name`	Name of table or view to which to enable a Data Redaction policy
`policy_name`	Name of policy to be enabled

Exceptions

- `ORA-28068` - The object *`object`* does not have a Data Redaction policy.
- `ORA-28071` - The action is not valid.
- `ORA-28072` - The specified policy name is incorrect.
- `ORA-28079` - The policy was already enabled.

Usage Notes

See DBMS_REDACT Security Model for a list of the required privileges for this procedure.

Examples

```
BEGIN
   DBMS_REDACT.ENABLE_POLICY (
      object_schema    =>  'hr',
      object_name      =>  'employees',
      policy_name      =>  'mask_emp_ids');
END;
```

143.5.9 UPDATE_FULL_REDACTION_VALUES Procedure

This procedure modifies the default displayed values for a Data Redaction policy for full redaction.

Syntax

```
DBMS_REDACT.UPDATE_FULL_REDACTION_VALUES (
   number_val       IN NUMBER                    :=  NULL,
   binfloat_val     IN BINARY_FLOAT              :=  NULL,
   bindouble_val    IN BINARY_DOUBLE             :=  NULL,
   char_val         IN CHAR                      :=  NULL,
   varchar_val      IN VARCHAR2                  :=  NULL,
   nchar_val        IN NCHAR                     :=  NULL,
   nvarchar_val     IN NVARCHAR2                 :=  NULL,
   date_val         IN DATE                      :=  NULL,
   ts_val           IN TIMESTAMP                 :=  NULL,
   tswtz_val        IN TIMESTAMP WITH TIME ZONE  :=  NULL,
   blob_val         IN BLOB                      :=  NULL,
   clob_val         IN CLOB                      :=  NULL,
   nclob_val        IN NCLOB                    NULL);
```

Parameters

Table 143-14 ***UPDATE_FULL_REDACTION_VALUES Procedure Parameters***

Parameter	Description
number_val	Modifies the default value for columns of the NUMBER datatype
binfloat_val	Modifies the default value for columns of the BINARY_FLOAT datatype
bindouble_val	Modifies the default value for columns of the BINARY_DOUBLE datatype
char_val	Modifies the default value for columns of the CHAR datatype
varchar_val	Modifies the default value for columns of the VARCHAR2 datatype
nchar_val	Modifies the default value for columns of the NCHAR datatype
nvarchar_val	Modifies the default value for columns of the NVARCHAR2 datatype
date	Modifies the default value for columns of the DATE datatype
ts_val	Modifies the default value for columns of the TIMESTAMP datatype
tswtz_val	Modifies the default value for columns of the TIMESTAMP WITH TIME ZONE datatype
blob_val	Modifies the default value for columns of the BLOB datatype
clob_val	Modifies the default value for columns of the CLOB datatype
nclob_val	Modifies the default value for columns of the NCLOB datatype

Exceptions

ORA-28082 - The parameter *parameter* is invalid (where the possible values are char_val, nchar_val, varchar_val and nvarchar_val)

Usage Notes

See DBMS_REDACT Security Model for a list of the required privileges for this procedure.

143.5.10 UPDATE_POLICY_EXPRESSION Procedure

This procedure updates a named Oracle Data Redaction policy expression.

Syntax

```
DBMS_REDACT.UPDATE_POLICY_EXPRESSION (
   policy_expression_name          IN    VARCHAR2,
   expression                      IN    VARCHAR2,
   policy_expression_description   IN    VARCHAR2 := NULL);
```

Parameters

Table 143-15 ***UPDATE_POLICY_EXPRESSION Procedure Parameters***

Parameter	Description
`policy_expression_name`	Name of the policy expression
`expression`	Definition of the policy expression
`policy_expression_description`	Description of the policy expression

Exceptions

- `ORA-28082` - The parameter *parameter* is invalid.
- `ORA-28092` - The parameter *parameter* with value *value* has an error.

Usage Notes

See DBMS_REDACT Security Model for a list of the required privileges for this procedure.

You can find existing policy expressions by querying the `REDACTION_EXPRESSIONS` data dictionary view.

Example

```
BEGIN
   DBMS_REDACT.UPDATE_POLICY_EXPRESSION(
     policy_expression_name         => 'oe_redact_pol',
     expression                     => 'SYS_CONTEXT(''USERENV'',''SESSION_USER'') !=
''OE''''),
     policy_expression_description  => 'Disables policy for user OE ');
END;
```

144
DBMS_REDEFINITION

The DBMS_REDEFINITION package provides an interface to perform an online redefinition of tables.

This chapter contains the following topics:

- Overview
- Security Model
- Constants
- Operational Notes
- Rules and Limits
- Examples
- Summary of DBMS_REDEFINITION Subprograms

> **See Also:**
>
> *Oracle Database Administrator's Guide* for more information about online redefinition of tables

144.1 DBMS_REDEFINITION Overview

To achieve online redefinition, incrementally maintainable local materialized views are used. These logs keep track of the changes to the master tables and are used by the materialized views during refresh synchronization.

144.2 DBMS_REDEFINITION Security Model

Subprograms in the DBMS_REDEFINITION package are run with invokers' rights (with the privileges of the current user).

There are two modes:

- In USER mode, the user who has the CREATE TABLE and CREATE MVIEW privileges may redefine a table residing in his own schema.
- In FULL mode, the user who has the ANY privilege may redefine tables in any schema.

144.3 DBMS_REDEFINITION Constants

The DBMS_REDEFINITION package defines several constants for specifying parameter values.

Table 144-1 DBMS_REDEFINITION Constants

Constant	Type	Value	Description
CONS_CONSTRAINT	PLS_INTEGER	3	Used to specify that dependent object type is a constraint
CONS_INDEX	PLS_INTEGER	2	Used to specify that dependent object type is a index
CONS_MVLOG	PLS_INTEGER	10	Used to (un)register a materialized view log, as a dependent object of the table, through the REGISTER_DEPENDENT_OBJECT Procedureand the UNREGISTER_DEPENDENT_OBJECT Procedure.
CONS_ORIG_PARAMS	PLS_INTEGER	1	Used to specify that indexes should be cloned with their original storage parameters
CONS_TRIGGER	PLS_INTEGER	4	Used to specify that dependent object type is a trigger
CONS_USE_PK	BINARY_INTEGER	1	Used to indicate that the redefinition should be done using primary keys or pseudo-primary keys (unique keys with all component columns having not-NULL constraints)
CONS_USE_ROWID	BINARY_INTEGER	2	Used to indicate that the redefinition should be done using rowids
CONS_VPD_AUTO	BINARY_INTEGER	2	Used to indicate to copy VPD policies automatically
CONS_VPD_MANUAL	BINARY_INTEGER	4	Used to indicate to copy VPD policies manually
CONS_VPD_NONE	BINARY_INTEGER	1	Used to indicate that there are no VPD policies on the original table

144.4 DBMS_REDEFINITION Operational Notes

The following operational notes apply to DBMS_REDEFINITION.

- CONS_USE_PK and CONS_USE_ROWID are constants used as input to the "options_flag" parameter in both the START_REDEF_TABLE Procedure and CAN_REDEF_TABLE Procedure. CONS_USE_ROWID is used to indicate that the redefinition should be done using rowids while CONS_USE_PK implies that the redefinition should be done using primary keys or pseudo-primary keys (which are unique keys with all component columns having NOT NULL constraints).
- CONS_INDEX, CONS_MVLOG,CONS_TRIGGER and CONS_CONSTRAINT are used to specify the type of the dependent object being (un)registered in REGISTER_DEPENDENT_OBJECT Procedure and UNREGISTER_DEPENDENT_OBJECT Procedure (parameter "dep_type").

  CONS_INDEX ==> dependent object is of type INDEX

  CONS_TRIGGER ==> dependent object is of type TRIGGER

CONS_CONSTRAINT==> dependent object type is of type CONSTRAINT

CONS_MVLOG ==> dependent object is of type MATERIALIZED VIEW LOG

- CONS_ORIG_PARAMS as used as input to the "copy_indexes" parameter in COPY_TABLE_DEPENDENTS Procedure. Using this parameter implies that the indexes on the original table be copied onto the interim table using the same storage parameters as that of the original index.

144.5 DBMS_REDEFINITION Rules and Limits

Various rules and limits apply to implementation of the DBMS_REDEFINITION package.

For more information about these, see the *Oracle Database Administrator's Guide*.

144.6 DBMS_REDEFINITION Examples

The following examples demonstrate DBMS_REDEFINITION functionality.

We create two tables EMP and EMP_INT as the original and the interim tables, respectively:

```
CREATE TABLE "EMP"
( "EMPNO" NUMBER(4,0) PRIMARY KEY,
"ENAME" VARCHAR2(10),
"JOB" VARCHAR2(9),
"MGR" NUMBER(4,0),
"HIREDATE" DATE,
"SAL" NUMBER(7,2),
"COMM" NUMBER(7,2),
"DEPTNO" NUMBER(2,0))

TABLESPACE myts;

CREATE TABLE "EMP_INT"
( "EMPNO" NUMBER(4,0) PRIMARY KEY,
"ENAME" VARCHAR2(10),
"JOB" VARCHAR2(9),
"MGR" NUMBER(4,0),
"HIREDATE" DATE,
"SAL" NUMBER(7,2),
"COMM" NUMBER(7,2),
"DEPTNO" NUMBER(2,0))

TABLESPACE compressed_ts;
```

Regular Multi-Step Redefinition

```
DBMS_REDEFINITION.START_REDEF_TABLE('SCOTT', 'EMP', 'EMP_INT',
ENABLE_ROLLBACK => TRUE);
DBMS_REDEFINITION.FINISH_REDEF_TABLE('SCOTT', 'EMP', 'EMP_INT');
```

Assume theDBA wants to evaluate the performance of the application for 2 days, after moving the table EMP from tablespace myts to compressed_ts. One can run

sync_interim_table SYNC_INTERIM_TABLE Procedureto keep both the tables in sync (say, every hour).

```
DBMS_REDEFINITION.SYNC_INTERIM_TABLE('SCOTT', 'EMP', 'EMP_INT');
```

Case 1 — DBA is not happy with the performance, so decides to rollback.

```
DBMS_REDEFINITION.ROLLBACK('SCOTT', 'EMP', 'EMP_INT');
```

Case 2 — DBA is happy with the performance, so decides not to rollback.

```
DBMS_REDEFINITION.ABORT_ROLLBACK('SCOTT', 'EMP', 'EMP_INT');
```

This terminates the possibility of rollback.

Single-Step Redefinition

```
DBMS_REDEFINITION.REDEF_TABLE('SCOTT','EMP','ROW STORE COMPRESS
ADVANCED', enable_rollback => TRUE);
```

> **Note:**
>
> Online table redefinition rollback is not supported when the `REDEF_TABLE` procedure is used to redefine a table.

144.7 Summary of DBMS_REDEFINITION Subprograms

This table lists the `DBMS_REDEFINITION` subprograms and briefly describes them.

Table 144-2 DBMS_REDEFINITION Package Subprograms

Subprogram	Description
ABORT_REDEF_TABLE Procedure	Cleans up errors that occur during the redefinition process and removes all temporary objects created by the reorganization process
ABORT_ROLLBACK Procedure	Aborts rollback
ABORT_UPDATE Procedure	Aborts an update started with the `EXECUTE_UPDATE` procedure
CAN_REDEF_TABLE Procedure	Determines if a given table can be redefined online
COPY_TABLE_DEPENDENTS Procedure	Copies the dependent objects of the original table onto the interim table
EXECUTE_UPDATE Procedure	Optimizes the performance of bulk updates to a table
FINISH_REDEF_TABLE Procedure	Completes the redefinition process

Table 144-2 (Cont.) DBMS_REDEFINITION Package Subprograms

Subprogram	Description
REDEF_TABLE Procedure	Provides a single push-button interface that integrates several redefinition steps
REGISTER_DEPENDENT_OBJECT Procedure	Registers a dependent object (index, trigger, constraint or materialized view log) on the table being redefined and the corresponding dependent object on the interim table
ROLLBACK Procedure	Performs rollback
SET_PARAM Procedure	Sets a new value for a specified parameter used by the redefinition process identified by a redefinition ID
START_REDEF_TABLE Procedure	Initiates the redefinition process
SYNC_INTERIM_TABLE Procedure	Keeps the interim table synchronized with the original table
UNREGISTER_DEPENDENT_OBJECT Procedure	Unregisters a dependent object (index, trigger, constraint or materialized view log) on the table being redefined and the corresponding dependent object on the interim table

144.7.1 ABORT_REDEF_TABLE Procedure

This procedure cleans up errors that occur during the redefinition process.

This procedure can also be used to terminate the redefinition process any time after the START_REDEF_TABLE Procedure has been called and before the FINISH_REDEF_TABLE Procedure is called. This process will remove the temporary objects that are created by the redefinition process such as materialized view logs.

Syntax

```
DBMS_REDEFINITION.ABORT_REDEF_TABLE (
   uname                  IN  VARCHAR2,
   orig_table             IN  VARCHAR2,
   int_table              IN  VARCHAR2,
   part_name              IN  VARCHAR2 := NULL);
```

Parameters

Table 144-3 ABORT_REDEF_TABLE Procedure Parameters

Parameter	Description
uname	Schema name of the tables
orig_table	Name of the table to be redefined
int_table	Name of the interim table. Can take a comma-delimited list of interim table names.
part_name	Name of the partition being redefined. If redefining only a single partition of a table, specify the partition name in this parameter. NULL implies the entire table is being redefined. Can take a comma-delimited list of partition names to be redefined.

144.7.2 ABORT_ROLLBACK Procedure

This procedure aborts rollback for a table that was redefined.

When online redefinition of a table is started with the START_REDEF_TABLE procedure, rollback can be enabled for the changes performed by online redefinition of a table by setting the enable_rollback parameter to TRUE. If you want to retain the changes made by online redefinition, you can abort the rollback to clean up the database objects that enable rollback.

Syntax

```
DBMS_REDEFINITION.ABORT_ROLLBACK (
   uname           IN  VARCHAR2,
   orig_table      IN  VARCHAR2,
   int_table       IN  VARCHAR2 := NULL,
   part_name       IN  VARCHAR2 := NULL);
```

Parameters

Table 144-4 ABORT_ROLLBACK Procedure Parameters

Parameter	Description
uname	Schema name of the tables
orig_table	Name of the table to be redefined
int_table	Name of the interim table
part_name	Name of the partition being redefined

144.7.3 ABORT_UPDATE Procedure

This procedure can aborts an update started with the EXECUTE_UPDATE procedure in the RDBMS_REDEFINITION package.

Syntax

```
DBMS_REDEFINITION.ABORT_UPDATE (
   update_stmt  IN  CLOB);
```

Parameters

Table 144-5 ABORT_UPDATE Procedure Parameters

Parameter	Description
update_stmt	The SQL UPDATE statement to be aborted The SQL statement must exactly match the SQL statement in the EXECUTE_UPDATE procedure.

> **See Also:**
>
> *Oracle Database Administrator's Guide*

144.7.4 CAN_REDEF_TABLE Procedure

This procedure determines if a given table can be redefined online. This is the first step of the online redefinition process. If the table is not a candidate for online redefinition, an error message is raised.

Syntax

```
DBMS_REDEFINITION.CAN_REDEF_TABLE (
   uname         IN  VARCHAR2,
   tname        IN  VARCHAR2,
   options_flag  IN  PLS_INTEGER := 1,
   part_name     IN  VARCHAR2 := NULL);
```

Parameters

Table 144-6 CAN_REDEF_TABLE Procedure Parameters

Parameter	Description
`uname`	Schema name of the table
`tname`	Name of the table to be re-organized
`options_flag`	Indicates the type of redefinition method to use. • If `dbms_redefinition.cons_use_pk`, the redefinition is done using primary keys or pseudo-primary keys (unique keys with all component columns having `NOT NULL` constraints). The default method of redefinition is using primary keys. • If `dbms_redefinition.cons_use_rowid`, the redefinition is done using rowids.
`part_name`	Name of the partition being redefined. If redefining only a single partition of a table, specify the partition name in this parameter. `NULL` implies the entire table is being redefined.

Exceptions

If the table is not a candidate for online redefinition, an error message is raised.

144.7.5 COPY_TABLE_DEPENDENTS Procedure

This procedure clones the dependent objects of the table being redefined onto the interim table and registers the dependent objects. This procedure does not clone the already registered dependent objects.

This subprogram is used to clone the dependent objects like grants, triggers, constraints and privileges from the table being redefined to the interim table (which represents the post-redefinition table).

Syntax

```
DBMS_REDEFINITION.COPY_TABLE_DEPENDENTS(
   uname                    IN  VARCHAR2,
   orig_table               IN  VARCHAR2,
   int_table                IN  VARCHAR2,
   copy_indexes             IN  PLS_INTEGER := 1,
   copy_triggers            IN  BOOLEAN     := TRUE,
   copy_constraints         IN  BOOLEAN     := TRUE,
   copy_privileges          IN  BOOLEAN     := TRUE,
   ignore_errors            IN  BOOLEAN     := FALSE,
   num_errors               OUT PLS_INTEGER,
   copy_statistics          IN  BOOLEAN     := FALSE,
   copy_mvlog               IN  BOOLEAN     := FALSE);
```

Parameters

Table 144-7 COPY_TABLE_DEPENDENTS Procedure Parameters

Parameter	Description
uname	Schema name of the tables
orig_table	Name of the table being redefined
int_table	Name of the interim table
copy_indexes	Flag indicating whether to copy the indexes • 0 - do not copy any index • dbms_redefinition.cons_orig_params – copy the indexes using the physical parameters of the source indexes
copy_triggers	TRUE = clone triggers, FALSE = do nothing
copy_constraints	TRUE = clone constraints, FALSE = do nothing. If compatibility setting is 10.2 or higher, then clone CHECK and NOT NULL constraints
copy_privileges	TRUE = clone privileges, FALSE = do nothing
ignore_errors	TRUE = if an error occurs while cloning a particular dependent object, then skip that object and continue cloning other dependent objects. FALSE = that the cloning process should stop upon encountering an error.
num_errors	Number of errors that occurred while cloning dependent objects
copy_statistics	TRUE = copy statistics, FALSE = do nothing
copy_mvlog	TRUE = copy materialized view log, FALSE = do nothing

Usage Notes

- The user must check the column num_errors before proceeding to ensure that no errors occurred during the cloning of the objects.
- In case of an error, the user should fix the cause of the error and call the COPY_TABLE_DEPENDENTS Procedure again to clone the dependent object. Alternatively the user can manually clone the dependent object and then register the manually cloned dependent object using the REGISTER_DEPENDENT_OBJECT Procedure.

- All cloned referential constraints involving the interim tables will be created disabled (they will be automatically enabled after the redefinition) and all triggers on interim tables will not fire till the redefinition is completed. After the redefinition is complete, the cloned objects will be renamed to the corresponding pre-redefinition names of the objects (from which they were cloned from).
- It is the user's responsibility that the cloned dependent objects are unaffected by the redefinition. All the triggers will be cloned and it is the user's responsibility that the cloned triggers are unaffected by the redefinition.

144.7.6 EXECUTE_UPDATE Procedure

This procedure can optimize the performance of bulk updates to a table. Performance is optimized because the updates are not logged in the redo log.

The `EXECUTE_UPDATE` procedure automatically uses the components of online table redefinition, such an interim table, a materialized view, and a materialized view log, to enable optimized bulk updates to a table. The `EXECUTE_UPDATE` procedure also removes fragmentation of the affected rows and ensures that the update is atomic. If the bulk updates raise any errors, then you can use the `ABORT_UPDATE` procedure to undo the changes made by the `EXECUTE_UPDATE` procedure.

Syntax

```
DBMS_REDEFINITION.EXECUTE_UPDATE (
   update_stmt  IN  CLOB);
```

Parameters

Table 144-8 EXECUTE_UPDATE Procedure Parameters

Parameter	Description
`update_stmt`	The SQL UPDATE statement

> **See Also:**
>
> *Oracle Database Administrator's Guide*

144.7.7 FINISH_REDEF_TABLE Procedure

This procedure completes the redefinition process.

Before this step, you can create new indexes, triggers, grants, and constraints on the interim table. The referential constraints involving the interim table must be disabled. After completing this step, the original table is redefined with the attributes and data of the interim table. The original table is locked briefly during this procedure.

Syntax

```
DBMS_REDEFINITION.FINISH_REDEF_TABLE (
   uname                   IN   VARCHAR2,
   orig_table              IN   VARCHAR2,
```

```
   int_table               IN   VARCHAR2,
   part_name               IN   VARCHAR2 := NULL,
   dml_lock_timeout        IN   PLS_INTEGER := NULL,
   continue_after_errors   IN   BOOLEAN := FALSE,
   disable_rollback        IN   PLS_INTEGER := FALSE);
```

Parameters

Table 144-9 FINISH_REDEF_TABLE Procedure Parameters

Parameters	Description
uname	Schema name of the tables
orig_table	Name of the table to be redefined
int_table	Name of the interim table. Can take a comma-delimited list of interim table names.
part_name	Name of the partition being redefined. If redefining only a single partition of a table, specify the partition name in this parameter. NULL implies the entire table is being redefined. Can take a comma-delimited list of partition names to be redefined.
dml_lock_timeout	Specifies the number of seconds the procedure waits for its required locks before failing. The permissible range of values for timeout is 0 to 1,000,000. The default is NULL (wait mode).
continue_after_errors	When redefining multiple partitions allows operation execution to continue on the next partition (applies only to batched partition redefinition).
disable_rollback	When set to TRUE, disables the rollback option if it was enabled in the START_REDEF_TABLE procedure. Specifying TRUE cleans up the database objects that enable rollback.

Examples

Wait up to 600 seconds for required locks on SH.SALES:

```
EXECUTE DBMS_REDEFINITION.FINISH_REDEF_TABLE (
  'SH', 'SALES', 'INT_SALES', 600);
```

144.7.8 REDEF_TABLE Procedure

This procedure provides a single interface that integrates several redefinition steps including the CAN_REDEF_TABLE Procedure, the START_REDEF_TABLE Procedure, the COPY_TABLE_DEPENDENTS Procedure and the FINISH_REDEF_TABLE Procedure.

This procedure can change data storage properties including tablespaces (for table, partition, subpartition, index, LOB column), compress type (for table, partition, subpartition, index, LOB column) and STORE_AS clause for the LOB column.

Syntax

```
DBMS_REDEFINITION.REDEF_TABLE (
   uname                       IN  VARCHAR2,
   tname                       IN  VARCHAR2,
   table_compression_type      IN  VARCHAR2 := NULL,
   table_part_tablespace       IN  VARCHAR2 := NULL,
   index_key_compression_type  IN  VARCHAR2 := NULL,
```

```
   index_tablespace            IN  VARCHAR2 := NULL,
   lob_compression_type        IN  VARCHAR2 := NULL,
   lob_tablespace              IN  VARCHAR2 := NULL,
   lob_store_as                IN  VARCHAR2 := NULL,
   refresh_dep_mviews          IN  VARCHAR2 := 'N',
   dml_lock_timeout            IN  PLS_INTEGER := NULL);
```

Parameters

Table 144-10 REDEF_TABLE Procedure Parameters

Parameter	Description
uname	Schema name of the table
tname	Name of the table to be redefined
table_compression_type	Text string of the table compression clause. NULL means there is no change.
table_part_tablespace	Tablespace name for the entire table or partitions. NULL means there is no change.
index_key_compression_type	Text string of the compression clause for all indexes on the table. NULL means there is no change.
index_tablespace	Tablespace name for all indexes on the table. NULL means there is no change.
lob_compression_type	Text string of the compression clause for all LOBs in the entire table. NULL means there is no change.
lob_tablespace	Tablespace name for all LOBs in the table. NULL means there is no change.
lob_store_as	Specifies LOB store as 'SECUREFILE' or 'BASICFILE'. NULL means there is no change.
refresh_dep_mviews	When set to 'Y', fast refresh of dependent materialized views is performed once at the end of the redefinition operation.
dml_lock_timeout	Specifies the number of seconds the procedure waits for its required locks before failing. The permissible range of values for timeout is 0 to 1,000,000. The default is NULL (wait mode).

Examples

```
BEGIN
   DBMS_REDEFINITION.REDEF_TABLE(
     uname                        => 'TABOWNER2',
     tname                        => 'EMP2',
     table_compression_type       => 'ROW STORE COMPRESS ADVANCED',
     table_part_tablespace        => 'NEWTBS',
     index_key_compression_type   => 'COMPRESS 1',
     index_tablespace             => 'NEWIDXTBS',
     lob_compression_type         => 'COMPRESS HIGH',
     lob_tablespace               => 'SLOBTBS',
     lob_store_as                 => 'SECUREFILE');
END;
```

Related Topics

- CAN_REDEF_TABLE Procedure
  This procedure determines if a given table can be redefined online. This is the first step of the online redefinition process. If the table is not a candidate for online redefinition, an error message is raised.
- START_REDEF_TABLE Procedure
  This procedure starts a table redefinition.
- COPY_TABLE_DEPENDENTS Procedure
  This procedure clones the dependent objects of the table being redefined onto the interim table and registers the dependent objects. This procedure does not clone the already registered dependent objects.
- FINISH_REDEF_TABLE Procedure
  This procedure completes the redefinition process.

> **See Also:**
>
> *Oracle Database Administrator's Guide* regarding "Performing Online Redefinition with the `REDEF_TABLE` Procedure"

144.7.9 REGISTER_DEPENDENT_OBJECT Procedure

This procedure registers a dependent object (index, trigger, constraint or materialized view log) on the table being redefined and the corresponding dependent object on the interim table.

This can be used to have the same object on each table but with different attributes. For example: for an index, the storage and tablespace attributes could be different but the columns indexed remain the same

Syntax

```
DBMS_REDEFINITION.REGISTER_DEPENDENT_OBJECT(
   uname                  IN    VARCHAR2,
   orig_table             IN    VARCHAR2,
   int_table              IN    VARCHAR2,
   dep_type               IN    PLS_INTEGER,
   dep_owner              IN    VARCHAR2,
   dep_orig_name          IN    VARCHAR2,
   dep_int_name           IN    VARCHAR2);
```

Parameters

Table 144-11 REGISTER_DEPENDENT_OBJECT Procedure Parameters

Parameters	Description
`uname`	Schema name of the tables
`orig_table`	Name of the table to be redefined
`int_table`	Name of the interim table

Table 144-11 (Cont.) REGISTER_DEPENDENT_OBJECT Procedure Parameters

Parameters	Description
dep_type	Type of the dependent object (see Constants and Operational Notes)
dep_owner	Owner of the dependent object
dep_orig_name	Name of the original dependent object
dep_int_name	Name of the interim dependent object

Usage Notes

- Attempting to register an already registered object will raise an error.
- Registering a dependent object will automatically remove that object from DBA_REDEFINITION_ERRORS if an entry exists for that object.

144.7.10 ROLLBACK Procedure

This procedure rolls back changes to a table after online table redefinition to return the table to its original definition and preserve DML changes made to the table.

Syntax

```
DBMS_REDEFINITION.ROLLBACK (
   uname                  IN  VARCHAR2,
   orig_table             IN  VARCHAR2,
   int_table              IN  VARCHAR2 := NULL,
   part_name              IN  VARCHAR2 := NULL,
   dml_lock_timeout       IN  PLS_INTEGER := NULL,
   continue_after_errors  IN  BOOLEAN := FALSE);
```

Parameters

Table 144-12 ROLLBACK Procedure Parameters

Parameter	Description
uname	Schema name of the table to be redefined
orig_table	Name of the table to be redefined
int_table	Name of the interim table.
part_name	Name of the partition being redefined.
dml_lock_timeout	Specifies the number of seconds the procedure waits for its required locks before failing. The permissible range of values for timeout is 0 to 1,000,000. The default is NULL (wait mode).
continue_after_errors	When rolling back redefinition changes on multiple partitions, allows operation execution to continue on the next partition (applies only to batched partition redefinition).

144.7.11 SET_PARAM Procedure

This procedure sets a new value for a specified parameter used by the redefinition process identified by a redefinition ID.

> **Note:**
>
> Currently, the only value that can be changed by this procedure is the value for the of the `refresh_dep_mviews` parameter that is specified in the `REDEF_TABLE` procedure or the `START_REDEF_TABLE` procedure. You can determine the redefinition ID and check the value of the `refresh_dep_mviews` parameter for an online table redefinition operation by querying the `DBA_REDEFINITION_STATUS` view.

Syntax

```
DBMS_REDEFINITION.SET_PARAM (
   redefinition_id  IN  VARCHAR2,
   param_name       IN  VARCHAR2,
   param_value      IN  VARCHAR2);
```

Parameters

Table 144-13 SET_PARAM Procedure Parameters

Parameter	Description
`redefinition_id`	The redefinition ID that identifies the redefinition process
`param_name`	The parameter name
`param_value`	The new parameter value

> **See Also:**
>
> *Oracle Database Administrator's Guide*

144.7.12 START_REDEF_TABLE Procedure

This procedure starts a table redefinition.

Prior to calling this procedure, you must manually create an empty interim table (in the same schema as the table to be redefined) with the desired attributes of the post-redefinition table, and then call this procedure to initiate the redefinition.

Syntax

```
DBMS_REDEFINITION.START_REDEF_TABLE (
   uname                   IN  VARCHAR2,
   orig_table              IN  VARCHAR2,
```

```
  int_table               IN  VARCHAR2,
  col_mapping             IN  VARCHAR2 := NULL,
  options_flag            IN  BINARY_INTEGER := 1,
  orderby_cols            IN  VARCHAR2 := NULL,
  part_name               IN  VARCHAR2 := NULL,
  continue_after_errors   IN  BOOLEAN := FALSE,
  copy_vpd_opt            IN  BINARY_INTEGER := CONS_VPD_NONE,
  refresh_dep_mviews      IN  VARCHAR2 := 'N',
  enable_rollback         IN  BOOLEAN := FALSE);
```

Parameters

Table 144-14 START_REDEF_TABLE Procedure Parameters

Parameter	Description
uname	Schema name of the tables
orig_table	Name of the table to be redefined
int_table	Name of the interim table. Can take a comma-delimited list of interim table names.
col_mapping	Mapping information from the columns in the original table to the columns in the interim table. (This is similar to the column list on the SELECT clause of a query.) If NULL, all the columns in the original table are selected and have the same name after redefinition.
options_flag	Indicates the type of redefinition method to use: • If dbms_redefinition.cons_use_pk, the redefinition is done using primary keys or pseudo-primary keys (unique keys with all component columns having NOT NULL constraints). The default method of redefinition is using primary keys. • If dbms_redefinition.cons_use_rowid, the redefinition is done using rowids.
orderby_cols	This optional parameter accepts the list of columns (along with the optional keyword(s) ascending/descending) with which to order by the rows during the initial instantiation of the interim table (the order by is only done for the initial instantiation and not for subsequent synchronizations)
part_name	Name of the partition being redefined. If redefining only a single partition of a table, specify the partition name in this parameter. NULL implies the entire table is being redefined. Can take a comma-delimited list of partition names to be redefined.
continue_after_errors	When redefining multiple partitions allows operation execution to continue on the next partition (applies only to batched partition redefinition)
copy_vpd_opt	Specifies how VPD policies are handled in online redefinition
refresh_dep_mviews	When set to 'Y', fast refresh of dependent materialized views is performed when the START_REDEF_TABLE procedure is run, each time the SYNC_INTERIM_TABLE procedure is run, and when the FINISH_REDEF_TABLE procedure is run.

Table 144-14 (Cont.) START_REDEF_TABLE Procedure Parameters

Parameter	Description
enable_rollback	When set to TRUE, enables the rollback option. When this parameter is set to true, Oracle Database maintains the interim table created during redefinition after redefinition is complete. You can run the SYNC_INTERIM_TABLE procedure to synchronize the interim table periodically to apply DML changes made to the redefined table to the interim table. An internal materialized view and materialized view log enables maintenance of the interim table. If you decide to roll back the online table redefinition with the ROLLBACK procedure, then the interim table is synchronized, and Oracle Database switches back to it so that the table has its original definition.

Examples

Start redefinition of three partitions (sal03q1, sal03q2, sal03q3) in table 'STEVE.salestable' using three interim tables of int_salestable1, int_salestable2 and int_salestable3, respectively. The operation will continue on sal03q3 even if it fails on sal03q1.

```
DBMS_REDEFINITION.START_REDEF_TABLE(
   uname                 => 'STEVE',
   orig_table            => 'salestable',
   int_table             => 'int_salestable1, int_salestable2, int_salestable3',
   col_mapping           => NULL,
   options_flag          => DBMS_REDEFINITION.CONS_USE_ROWID,
   part_name             => 'sal03q1,sal03q2,sal03q3',
   continue_after_errors => TRUE);
```

Specify to copy VPD policies automatically:

```
EXECUTE DBMS_REDEFINITION.START_REDEF_TABLE (
  uname                 => 'SCOTT',
  orig_table            => 'T',
  int_table             => 'INT_T',
  copy_vpd_opt          => DBMS_REDEFINITION.CONS_VPD_AUTO);
```

144.7.13 SYNC_INTERIM_TABLE Procedure

This procedure keeps the interim table synchronized with the original table.

Syntax

```
DBMS_REDEFINITION.SYNC_INTERIM_TABLE (
   uname                 IN  VARCHAR2,
   orig_table            IN  VARCHAR2,
   int_table             IN  VARCHAR2,
   part_name             IN  VARCHAR2 := NULL,
   continue_after_errors IN  BOOLEAN := FALSE);
```

Parameters

Table 144-15 SYNC_INTERIM_TABLE Procedure Parameters

Parameter	Description
uname	Schema name of the table
orig_table	Name of the table to be redefined
int_table	Name of the interim table. Can take a comma-delimited list of interim table names.
part_name	Name of the partition being redefined. If redefining only a single partition of a table, specify the partition name in this parameter. NULL implies the entire table is being redefined. Can take a comma-delimited list of partition names to be redefined.
continue_after_errors	When redefining multiple partitions allows operation execution to continue on the next partition (applies only to batched partition redefinition)

Usage Notes

- This step is useful in minimizing the amount of synchronization needed to be done by the FINISH_REDEF_TABLE Procedure before completing the online redefinition.
- This procedure can be called between long running operations (such as CREATE INDEX) on the interim table to sync it up with the data in the original table and speed up subsequent operations.

144.7.14 UNREGISTER_DEPENDENT_OBJECT Procedure

This procedure unregisters a dependent object (index, trigger, constraint or materialized view log) on the table being redefined and the corresponding dependent object on the interim table.

Syntax

```
DBMS_REDEFINITION.UNREGISTER_DEPENDENT_OBJECT(
   uname             IN VARCHAR2,
   orig_table        IN VARCHAR2,
   int_table         IN VARCHAR2,
   dep_type          IN PLS_INTEGER,
   dep_owner         IN VARCHAR2,
   dep_orig_name     IN VARCHAR2,
   dep_int_name      IN  VARCHAR2);
```

Parameters

Table 144-16 UNREGISTER_DEPENDENT_OBJECT Procedure Parameters

Parameters	Description
uname	Schema name of the tables
orig_table	Name of the table to be redefined
int_table	Name of the interim table

Table 144-16 (Cont.) UNREGISTER_DEPENDENT_OBJECT Procedure Parameters

Parameters	Description
dep_type	Type of the dependent object
dep_owner	Owner of the dependent object
dep_orig_name	Name of the original dependent object
dep_int_name	Name of the interim dependent object

145
DBMS_REFRESH

The DBMS_REFRESH package enables you to create groups of materialized views that can be refreshed together to a transactionally consistent point in time. These groups are called refresh groups.

This chapter contains the following topics:

- DBMS_REFRESH Overview
- DBMS_REFRESH Security Model

145.1 DBMS_REFRESH Overview

When it is important for materialized views to be transactionally consistent with each other, you can organize them into refresh groups.

By refreshing the refresh group, you can ensure that the data in all of the materialized views in the refresh group correspond to the same transactionally consistent point in time. A materialized view in a refresh group still can be refreshed individually, but doing so nullifies the benefits of the refresh group because refreshing the materialized view individually does not refresh the other materialized views in the refresh group

145.2 DBMS_REFRESH Security Model

Users must have the EXECUTE privilege to run the procedures of DBMS_REFRESH package.

145.3 Summary of DBMS_REFRESH Subprograms

This table lists the DBMS_REFRESH subprograms and briefly describes them.

Table 145-1 DBMS_REFRESH Package Subprograms

Subprogram	Description
ADD Procedure	Adds materialized views to a refresh group
CHANGE Procedure	Changes the refresh interval for a refresh group
DESTROY Procedure	Removes all of the materialized views from a refresh group and deletes the refresh group
MAKE Procedure	Specifies the members of a refresh group and the time interval used to determine when to refresh the members of this group
REFRESH Procedure	Manually refreshes a refresh group
SUBTRACT Procedure	Removes materialized views from a refresh group

145.3.1 ADD Procedure

This procedure adds materialized views to a refresh group.

Syntax

```
DBMS_REFRESH.ADD (
   name     IN VARCHAR2,
   { list   IN VARCHAR2,
   | tab    IN DBMS_UTILITY.UNCL_ARRAY, }
   lax      IN BOOLEAN := FALSE);
```

> **Note:**
>
> This procedure is overloaded. The `list` and `tab` parameters are mutually exclusive.

Parameters

Table 145-2 ADD Procedure Parameters

Parameter	Description
`name`	Name of the refresh group to which you want to add members, specified as [*schema_name.*]*refresh_group_name*. If the schema is not specified, then the current user is the default.
`list`	Comma-delimited list of materialized views that you want to add to the refresh group. Synonyms are not supported. Each materialized view is specified as [*schema_name.*]*materialized_view_name*. If the schema is not specified, then the refresh group owner is the default.
`tab`	Instead of a comma-delimited list, you can supply a PL/SQL associative array of type `DBMS_UTILITY.UNCL_ARRAY`, where each element is the name of a materialized view. The first materialized view should be in position 1. The last position must be `NULL`. Each materialized view is specified as [*schema_name.*]*materialized_view_name*. If the schema is not specified, then the refresh group owner is the default.
`lax`	A materialized view can belong to only one refresh group at a time. If you are moving a materialized view from one group to another, then you must set the `lax` flag to `TRUE` to succeed. Oracle then automatically removes the materialized view from the other refresh group and updates its refresh interval to be that of its new group. Otherwise, the call to `ADD` generates an error message.

145.3.2 CHANGE Procedure

This procedure changes the refresh interval for a refresh group.

Syntax

```
DBMS_REFRESH.CHANGE (
   name                 IN VARCHAR2,
   next_date            IN DATE           := NULL,
   interval             IN VARCHAR2       := NULL,
   implicit_destroy     IN BOOLEAN        := NULL,
   rollback_seg         IN VARCHAR2       := NULL,
   push_deferred_rpc    IN BOOLEAN        := NULL,
   refresh_after_errors IN BOOLEAN        := NULL,
   purge_option         IN BINARY_INTEGER := NULL,
   parallelism          IN BINARY_INTEGER := NULL,
   heap_size            IN BINARY_INTEGER := NULL);
```

Parameters

Table 145-3 CHANGE Procedure Parameters

Parameter	Description
name	Name of the refresh group for which you want to alter the refresh interval.
next_date	Next date that you want a refresh to occur. By default, this date remains unchanged.
interval	Function used to calculate the next time to refresh the materialized views in the refresh group. This interval is evaluated immediately before the refresh. Thus, select an interval that is greater than the time it takes to perform a refresh. By default, the interval remains unchanged.
implicit_destroy	Allows you to reset the value of the implicit_destroy flag. If this flag is set, then Oracle automatically deletes the group if it no longer contains any members. By default, this flag remains unchanged.
rollback_seg	Allows you to change the rollback segment used. By default, the rollback segment remains unchanged. To reset this parameter to use the default rollback segment, specify NULL, including the quotes. Specifying NULL without quotes indicates that you do not want to change the rollback segment currently being used.
push_deferred_rpc	Starting with Oracle Database 12*c* Release 2 (12.2), this parameter is ignored.
refresh_after_errors	Starting with Oracle Database 12*c* Release 2 (12.2), this parameter is ignored.
purge_option	Starting with Oracle Database 12*c* Release 2 (12.2), this parameter is ignored.
parallelism	• 0 specifies serial propagation. • *n* > 1 specifies parallel propagation with n parallel processes. • 1 specifies parallel propagation using only one parallel process.

Table 145-3 (Cont.) CHANGE Procedure Parameters

Parameter	Description
heap_size	Maximum number of transactions to be examined simultaneously for parallel propagation scheduling. Oracle automatically calculates the default setting for optimal performance. **Note:** Do not set this parameter unless directed to do so by Oracle Support Services.

145.3.3 DESTROY Procedure

This procedure removes all of the materialized views from a refresh group and delete the refresh group.

Syntax

```
DBMS_REFRESH.DESTROY (
   name    IN    VARCHAR2);
```

Parameters

Table 145-4 DESTROY Procedure Parameters

Parameter	Description
name	Name of the refresh group that you want to destroy.

145.3.4 MAKE Procedure

This procedure specifies the members of a refresh group and the time interval used to determine when to refresh the members of this group.

Syntax

```
DBMS_REFRESH.MAKE (
   name                  IN    VARCHAR2
   { list                IN    VARCHAR2,
   | tab                 IN    DBMS_UTILITY.UNCL_ARRAY,}
   next_date             IN    DATE,
   interval              IN    VARCHAR2,
   implicit_destroy      IN    BOOLEAN         := FALSE,
   lax                   IN    BOOLEAN         := FALSE,
   job                   IN    BINARY_INTEGER  := 0,
   rollback_seg          IN    VARCHAR2        := NULL,
   push_deferred_rpc     IN    BOOLEAN         := TRUE,
   refresh_after_errors  IN    BOOLEAN         := FALSE
   purge_option          IN    BINARY_INTEGER  := NULL,
   parallelism           IN    BINARY_INTEGER  := NULL,
   heap_size             IN    BINARY_INTEGER  := NULL
```

```
  job_name              IN    VARCHAR2        := NULL,
  auto_commit           IN    BOOLEAN         := NULL);
```

> **Note:**
>
> This procedure is overloaded. The `list` and `tab` parameters are mutually exclusive.

Parameters

Table 145-5 MAKE Procedure Parameters

Parameter	Description
`name`	Unique name used to identify the refresh group, specified as `[`*`schema_name`*`.]`*`refresh_group_name`*. If the schema is not specified, then the current user is the default. Refresh groups must follow the same naming conventions as tables.
`list`	Comma-delimited list of materialized views that you want to refresh. Synonyms are not supported. These materialized views can be located in different schemas and have different master tables or master materialized views. However, all of the listed materialized views must be in your current database. Each materialized view is specified as `[`*`schema_name`*`.]`*`materialized_view_name`*. If the schema is not specified, then the refresh group owner is the default.
`tab`	Instead of a comma-delimited list, you can supply a PL/SQL associative array of names of materialized views that you want to refresh using the data type `DBMS_UTILITY.UNCL_ARRAY`. If the table contains the names of *n* materialized views, then the first materialized view should be in position 1 and the *n* + 1 position should be set to `NULL`. Each materialized view is specified as `[`*`schema_name`*`.]`*`materialized_view_name`*. If the schema is not specified, then the refresh group owner is the default.
`next_date`	Next date that you want a refresh to occur.
`interval`	Function used to calculate the next time to refresh the materialized views in the group. This field is used with the `next_date` value. For example, if you specify `NEXT_DAY(SYSDATE+1, "MONDAY")` as your interval, and if your `next_date` evaluates to Monday, then Oracle refreshes the materialized views every Monday. This interval is evaluated immediately before the refresh. Thus, select an interval that is greater than the time it takes to perform a refresh.
`implicit_destroy`	Set this to `TRUE` to delete the refresh group automatically when it no longer contains any members. Oracle checks this flag only when you call the `SUBTRACT` procedure. That is, setting this flag still enables you to create an empty refresh group.
`lax`	A materialized view can belong to only one refresh group at a time. If you are moving a materialized view from an existing group to a new refresh group, then you must set this to `TRUE` to succeed. Oracle then automatically removes the materialized view from the other refresh group and updates its refresh interval to be that of its new group. Otherwise, the call to `MAKE` generates an error message.
`job`	Needed by the Import utility. Use the default value, 0.

Table 145-5 (Cont.) MAKE Procedure Parameters

Parameter	Description
rollback_seg	Name of the rollback segment to use while refreshing materialized views. The default, NULL, uses the default rollback segment.
push_deferred_rpc	Starting with Oracle Database 12*c* Release 2 (12.2), this parameter is ignored.
refresh_after_errors	Starting with Oracle Database 12*c* Release 2 (12.2), this parameter is ignored.
purge_option	Starting with Oracle Database 12*c* Release 2 (12.2), this parameter is ignored.
parallelism	• 0 specifies serial propagation. • *n* > 1 specifies parallel propagation with n parallel processes. • 1 specifies parallel propagation using only one parallel process.
heap_size	Maximum number of transactions to be examined simultaneously for parallel propagation scheduling. Oracle automatically calculates the default setting for optimal performance. **Note:** Do not set this parameter unless directed to do so by Oracle Support Services.
job_name	This parameter is needed by the import utility. User should use the default value, NULL.
auto_commit	Supported values are NULL, TRUE, and FALSE. • NULL—allows the user to continue using DBMS_JOB. • TRUE—commit statement will be automatically issued after the job of the refresh group are created by DBMS_REFRESH.MAKE. • FALSE—user must issue a commit statement to finish the transaction after calling DBMS_REFRESH.MAKE. The default value is NULL.

Usage Notes

Import utility and export utility need CREATE JOB privilege if DBMS_SCHEDULER jobs are used.

145.3.5 REFRESH Procedure

This procedure manually refreshes a refresh group.

Syntax

```
DBMS_REFRESH.REFRESH (
   name    IN    VARCHAR2);
```

Parameters

Table 145-6 REFRESH Procedure Parameters

Parameter	Description
name	Name of the refresh group that you want to refresh manually.

145.3.6 SUBTRACT Procedure

This procedure removes materialized views from a refresh group.

Syntax

```
DBMS_REFRESH.SUBTRACT (
   name      IN    VARCHAR2,
   { list    IN    VARCHAR2,
   | tab     IN    DBMS_UTILITY.UNCL_ARRAY, }
   lax       IN    BOOLEAN := FALSE);
```

> **Note:**
>
> This procedure is overloaded. The `list` and `tab` parameters are mutually exclusive.

Parameters

Table 145-7 SUBTRACT Procedure Parameters

Parameter	Description
name	Name of the refresh group from which you want to remove members, specified as [*schema_name.*]*refresh_group_name*. If the schema is not specified, then the current user is the default.
list	Comma-delimited list of materialized views that you want to remove from the refresh group. (Synonyms are not supported.) These materialized views can be located in different schemas and have different master tables or master materialized views. However, all of the listed materialized views must be in your current database. Each materialized view is specified as [*schema_name.*]*materialized_view_name*. If the schema is not specified, then the refresh group owner is the default.
tab	Instead of a comma-delimited list, you can supply a PL/SQL associative array of type DBMS_UTILITY.UNCL_ARRAY, where each element is the name of a materialized view. The first materialized view should be in position 1. The last position must be NULL. Each materialized view is specified as [*schema_name.*]*materialized_view_name*. If the schema is not specified, then the refresh group owner is the default.
lax	Set this to FALSE if you want Oracle to generate an error message if the materialized view you are attempting to remove is not a member of the refresh group.

146
DBMS_REPAIR

The DBMS_REPAIR package contains data corruption repair procedures that enable you to detect and repair corrupt blocks in tables and indexes. You can address corruptions where possible and continue to use objects while you attempt to rebuild or repair them.

This chapter contains the following topics:

- Overview
- Security Model
- Constants
- Operating Notes
- Exceptions
- Examples
- Summary of DBMS_REPAIR Subprograms

> **See Also:**
>
> For detailed information about using the DBMS_REPAIR package, see *Oracle Database Administrator's Guide*

146.1 DBMS_REPAIR Overview

The DBMS_REPAIR package is intended for use by database administrators only. It is not intended for use by application developers.

146.2 DBMS_REPAIR Security Model

The package is owned by SYS. Execution privilege is not granted to other users.

146.3 DBMS_REPAIR Constants

The DBMS_REPAIR package defines several enumerated constants that should be used for specifying parameter values. Enumerated constants must be prefixed with the package name. For example, DBMS_REPAIR.TABLE_OBJECT.

The following table lists the parameters and the enumerated constants.

Table 146-1 DBMS_REPAIR Parameters with Enumerated Constants

Parameter	Option	Type	Description
object_type	• TABLE_OBJECT • INDEX_OBJECT • CLUSTER_OBJECT	BINARY_INTEGER	-
action	• CREATE_ACTION • DROP_ACTION • PURGE_ACTION	BINARY_INTEGER	-
table_type	• REPAIR_TABLE • ORPHAN_TABLE	BINARY_INTEGER	-
flags	• SKIP_FLAG • NOSKIP_FLAG	BINARY_INTEGER	-
object_id	• ALL_INDEX_ID := 0	BINARY_INTEGER	Clean up all objects that qualify
wait_for_lock	• LOCK_WAIT := 1 • LOCK_NOWAIT := 0	BINARY_INTEGER	Specifies whether to try getting DML locks on underlying table [[sub]partition] object

> **Note:**
>
> The default table_name will be REPAIR_TABLE when table_type is REPAIR_TABLE, and will be ORPHAN_KEY_TABLE when table_type is ORPHAN_TABLE.

146.4 DBMS_REPAIR Operating Notes

The procedure to create the ORPHAN_KEYS_TABLE is similar to the one used to create the REPAIR_TABLE.

```
CONNECT / AS SYSDBA;
EXEC DBMS_REPAIR.ADMIN_TABLES('ORPHAN_KEYS_TABLE', DBMS_REPAIR.ORPHAN_TABLE,
                              DBMS_REPAIR.CREATE_ACTION);
EXEC DBMS_REPAIR.ADMIN_TABLES('REPAIR_TABLE', DBMS_REPAIR.REPAIR_TABLE,
                              DBMS_REPAIR.CREATE_ACTION);
DESCRIBE ORPHAN_KEYS_TABLE;
DESCRIBE REPAIR_TABLE;
SELECT * FROM ORPHAN_KEYS_TABLE;
SELECT * FROM REPAIR_TABLE;
```

The DBA would create the repair and orphan keys tables once. Subsequent executions of the CHECK_OBJECT Procedure would add rows into the appropriate table indicating the types of errors found.

The name of the repair and orphan keys tables can be chosen by the user, with the following restriction: the name of the repair table must begin with the 'REPAIR_' prefix, and the name of the orphan keys table must begin with the 'ORPHAN_' prefix. The following code is also legal:

```
CONNECT / AS SYSDBA;
EXEC DBMS_REPAIR.ADMIN_TABLES('ORPHAN_FOOBAR', DBMS_REPAIR.ORPHAN_TABLE,
```

```
                                DBMS_REPAIR.CREATE_ACTION);
EXEC DBMS_REPAIR.ADMIN_TABLES('REPAIR_ABCD', DBMS_REPAIR.REPAIR_TABLE,
                                DBMS_REPAIR.CREATE_ACTION);
DESCRIBE ORPHAN_FOOBAR;
DESCRIBE REPAIR_ABCD;
SELECT * FROM ORPHAN_FOOBAR;
SELECT * FROM REPAIR_ABCD;
```

When invoking the CHECK_OBJECT Procedure the name of the repair and orphan keys tables that were created should be specified correctly, especially if the default values were not used in the ADMIN_TABLES Procedure or `CREATE_ACTION`.

Other actions in the ADMIN_TABLES Procedure can be used to purge/delete the `REPAIR_TABLE` and the `ORPHAN_KEYS_TABLE`.

146.5 DBMS_REPAIR Exceptions

The table in this topic describes the exceptions raised by the DDBMS_REPAIR subprograms.

Table 146-2 DBMS_REPAIR Exceptions

Exception	Description	Action
942	Reported by `DBMS_REPAIR.ADMIN_TABLES` during a `DROP_ACTION` when the specified table doesn't exist.	-
955	Reported by `DBMS_REPAIR.CREATE_ACTION` when the specified table already exists.	-
24120	An invalid parameter was passed to the specified `DBMS_REPAIR` procedure.	Specify a valid parameter value or use the parameter's default.
24122	An incorrect block range was specified.	Specify correct values for the `BLOCK_START` and `BLOCK_END` parameters.
24123	An attempt was made to use the specified feature, but the feature is not yet implemented.	Do not attempt to use the feature.
24124	An invalid `ACTION` parameter was specified.	Specify `CREATE_ACTION`, `PURGE_ACTION` or `DROP_ACTION` for the `ACTION` parameter.
24125	An attempt was made to fix corrupt blocks on an object that has been dropped or truncated since `DBMS_REPAIR.CHECK_OBJECT` was run.	Use `DBMS_REPAIR.ADMIN_TABLES` to purge the repair table and run `DBMS_REPAIR.CHECK_OBJECT` to determine whether there are any corrupt blocks to be fixed.
24127	`TABLESPACE` parameter specified with an `ACTION` other than `CREATE_ACTION`.	Do not specify `TABLESPACE` when performing actions other than `CREATE_ACTION`.
24128	A partition name was specified for an object that is not partitioned.	Specify a partition name only if the object is partitioned.
24129	An attempt was made to pass a table name parameter without the specified prefix.	Pass a valid table name parameter.

Table 146-2 (Cont.) DBMS_REPAIR Exceptions

Exception	Description	Action
24130	An attempt was made to specify a repair or orphan table that does not exist.	Specify a valid table name parameter.
24131	An attempt was made to specify a repair or orphan table that does not have a correct definition.	Specify a table name that refers to a properly created table.
24132	An attempt was made to specify a table name is greater than 30 characters long.	Specify a valid table name parameter.

146.6 DBMS_REPAIR Examples

This topic shows examples of DBMS_REPAIR usage.

```
/* Fix the bitmap status for all the blocks in table mytab in schema sys */

EXECUTE DBMS_REPAIR.SEGMENT_FIX_STATUS('SYS', 'MYTAB');

/* Mark block number 45, filenumber 1 for table mytab in sys schema as FULL.*/

EXECUTE DBMS_REPAIR.SEGMENT_FIX_STATUS('SYS', 'MYTAB', TABLE_OBJECT,1, 45, 1);
```

146.7 Summary of DBMS_REPAIR Subprograms

This table lists the `DBMS_REPAIR` subprograms and briefly describes them.

Table 146-3 DBMS_REPAIR Package Subprograms

Subprogram	Description
ADMIN_TABLES Procedure	Provides administrative functions for the `DBMS_REPAIR` package repair and orphan key tables, including create, purge, and drop functions
CHECK_OBJECT Procedure	Detects and reports corruptions in a table or index
DUMP_ORPHAN_KEYS Procedure	Reports on index entries that point to rows in corrupt data blocks
FIX_CORRUPT_BLOCKS Procedure	Marks blocks software corrupt that have been previously detected as corrupt by `CHECK_OBJECT`
ONLINE_INDEX_CLEAN Function	Performs a manual cleanup of failed or interrupted online index builds or rebuilds
REBUILD_FREELISTS Procedure	Rebuilds an object's freelists
SEGMENT_FIX_STATUS Procedure	Fixes the corrupted state of a bitmap entry
SKIP_CORRUPT_BLOCKS Procedure	Sets whether to ignore blocks marked corrupt during table and index scans or to report `ORA-1578` when blocks marked corrupt are encountered

146.7.1 ADMIN_TABLES Procedure

This procedure provides administrative functions for the DBMS_REPAIR package repair and orphan key tables.

Syntax

```
DBMS_REPAIR.ADMIN_TABLES (
   table_name  IN   VARCHAR2,
   table_type  IN   BINARY_INTEGER,
   action      IN   BINARY_INTEGER,
   tablespace  IN   VARCHAR2  DEFAULT NULL);
```

Parameters

Table 146-4 ADMIN_TABLES Procedure Parameters

Parameter	Description
table_name	Name of the table to be processed. Defaults to ORPHAN_KEY_TABLE or REPAIR_TABLE based on the specified table_type. When specified, the table name must have the appropriate prefix: ORPHAN_ or REPAIR_.
table_type	Type of table; must be either ORPHAN_TABLE or REPAIR_TABLE. See "Constants".
action	Indicates what administrative action to perform. Must be either CREATE_ACTION, PURGE_ACTION, or DROP_ACTION. If the table already exists, and if CREATE_ACTION is specified, then an error is returned. PURGE_ACTION indicates to delete all rows in the table that are associated with non-existent objects. If the table does not exist, and if DROP_ACTION is specified, then an error is returned. When CREATE_ACTION and DROP_ACTION are specified, an associated view named DBA_<table_name> is created and dropped respectively. The view is defined so that rows associated with non-existent objects are eliminated. Created in the SYS schema. See "Constants".
tablespace	Indicates the tablespace to use when creating a table. By default, the SYS default tablespace is used. An error is returned if the tablespace is specified and if the action is not CREATE_ACTION.

146.7.2 CHECK_OBJECT Procedure

This procedure checks the specified objects and populates the repair table with information about corruptions and repair directives.

Validation consists of block checking all blocks in the object.

Syntax

```
DBMS_REPAIR.CHECK_OBJECT (
   schema_name       IN  VARCHAR2,
   object_name       IN  VARCHAR2,
```

```
partition_name    IN  VARCHAR2       DEFAULT NULL,
object_type       IN  BINARY_INTEGER DEFAULT TABLE_OBJECT,
repair_table_name IN  VARCHAR2       DEFAULT 'REPAIR_TABLE',
flags             IN  BINARY_INTEGER DEFAULT NULL,
relative_fno      IN  BINARY_INTEGER DEFAULT NULL,
block_start       IN  BINARY_INTEGER DEFAULT NULL,
block_end         IN  BINARY_INTEGER DEFAULT NULL,
corrupt_count     OUT BINARY_INTEGER);
```

Parameters

Table 146-5 CHECK_OBJECT Procedure Parameters

Parameter	Description
schema_name	Schema name of the object to be checked.
object_name	Name of the table or index to be checked.
partition_name	Partition or subpartition name to be checked. If this is a partitioned object, and if partition_name is not specified, then all partitions and subpartitions are checked. If this is a partitioned object, and if the specified partition contains subpartitions, then all subpartitions are checked.
object_type	Type of the object to be processed. This must be either TABLE_OBJECT (default) or INDEX_OBJECT. See "Constants".
repair_table_name	Name of the repair table to be populated. The table must exist in the SYS schema. Use the ADMIN_TABLES Procedure to create a repair table. The default name is REPAIR_TABLE.
flags	Reserved for future use.
relative_fno	Relative file number: Used when specifying a block range.
block_start	First block to process if specifying a block range. May be specified only if the object is a single table, partition, or subpartition.
block_end	Last block to process if specifying a block range. May be specified only if the object is a single table, partition, or subpartition. If only one of block_start or block_end is specified, then the other defaults to the first or last block in the file respectively.
corrupt_count	Number of corruptions reported.

Usage Notes

You may optionally specify a DBA range, partition name, or subpartition name when you want to check a portion of an object.

146.7.3 DUMP_ORPHAN_KEYS Procedure

This procedure reports on index entries that point to rows in corrupt data blocks. For each such index entry encountered, a row is inserted into the specified orphan table.

If the repair table is specified, then any corrupt blocks associated with the base table are handled in addition to all data blocks that are marked software corrupt. Otherwise, only blocks that are marked corrupt are handled.

This information may be useful for rebuilding lost rows in the table and for diagnostic purposes.

Syntax

```
DBMS_REPAIR.DUMP_ORPHAN_KEYS (
   schema_name       IN  VARCHAR2,
   object_name       IN  VARCHAR2,
   partition_name    IN  VARCHAR2       DEFAULT NULL,
   object_type       IN  BINARY_INTEGER DEFAULT INDEX_OBJECT,
   repair_table_name IN  VARCHAR2       DEFAULT 'REPAIR_TABLE',
   orphan_table_name IN  VARCHAR2       DEFAULT 'ORPHAN_KEYS_TABLE',
   flags             IN  BINARY_INTEGER DEFAULT NULL,
   key_count         OUT BINARY_INTEGER);
```

Parameters

Table 146-6 DUMP_ORPHAN_KEYS Procedure Parameters

Parameter	Description
schema_name	Schema name.
object_name	Object name.
partition_name	Partition or subpartition name to be processed. If this is a partitioned object, and if partition_name is not specified, then all partitions and subpartitions are processed. If this is a partitioned object, and if the specified partition contains subpartitions, then all subpartitions are processed.
object_type	Type of the object to be processed. The default is INDEX_OBJECT See "Constants".
repair_table_name	Name of the repair table that has information regarding corrupt blocks in the base table. The specified table must exist in the SYS schema. The ADMIN_TABLES Procedure is used to create the table.
orphan_table_name	Name of the orphan key table to populate with information regarding each index entry that refers to a row in a corrupt data block. The specified table must exist in the SYS schema. The ADMIN_TABLES Procedure is used to create the table.
flags	Reserved for future use.
key_count	Number of index entries processed.

146.7.4 FIX_CORRUPT_BLOCKS Procedure

This procedure fixes the corrupt blocks in specified objects based on information in the repair table that was previously generated by the CHECK_OBJECT Procedure.

Prior to effecting any change to a block, the block is checked to ensure the block is still corrupt. Corrupt blocks are repaired by marking the block software corrupt. When a repair is effected, the associated row in the repair table is updated with a fix timestamp.

Syntax

```
DBMS_REPAIR.FIX_CORRUPT_BLOCKS (
   schema_name       IN  VARCHAR2,
   object_name       IN  VARCHAR2,
   partition_name    IN  VARCHAR2       DEFAULT NULL,
   object_type       IN  BINARY_INTEGER DEFAULT TABLE_OBJECT,
   repair_table_name IN  VARCHAR2       DEFAULT 'REPAIR_TABLE',
   flags             IN  BINARY_INTEGER DEFAULT NULL,
   fix_count         OUT BINARY_INTEGER);
```

Parameters

Table 146-7 FIX_CORRUPT_BLOCKS Procedure Parameters

Parameter	Description
schema_name	Schema name.
object_name	Name of the object with corrupt blocks to be fixed.
partition_name	Partition or subpartition name to be processed. If this is a partitioned object, and if partition_name is not specified, then all partitions and subpartitions are processed. If this is a partitioned object, and if the specified partition contains subpartitions, then all subpartitions are processed.
object_type	Type of the object to be processed. This must be either TABLE_OBJECT (default) or INDEX_OBJECT. See "Constants".
repair_table_name	Name of the repair table with the repair directives. Must exist in the SYS schema.
flags	Reserved for future use.
fix_count	Number of blocks fixed.

Related Topics

- CHECK_OBJECT Procedure
  This procedure checks the specified objects and populates the repair table with information about corruptions and repair directives.

146.7.5 ONLINE_INDEX_CLEAN Function

This function performs a manual cleanup of failed or interrupted online index builds or rebuilds.

This action is also performed periodically by SMON, regardless of user-initiated cleanup.

This function returns `TRUE` if all indexes specified were cleaned up and `FALSE` if one or more indexes could not be cleaned up.

Syntax

```
DBMS_REPAIR.ONLINE_INDEX_CLEAN (
   object_id      IN BINARY_INTEGER DEFAULT ALL_INDEX_ID,
   wait_for_lock  IN BINARY_INTEGER DEFAULT LOCK_WAIT)
 RETURN BOOLEAN;
```

Parameters

Table 146-8 ONLINE_INDEX_CLEAN Function Parameters

Parameter	Description
`object_id`	Object id of index to be cleaned up. The default cleans up all object ids that qualify.
`wait_for_lock`	This parameter specifies whether to try getting DML locks on underlying table [[sub]partition] object. The default retries up to an internal retry limit, after which the lock get will give up. If `LOCK_NOWAIT` is specified, then the lock get does not retry.

146.7.6 REBUILD_FREELISTS Procedure

This procedure rebuilds the freelists for the specified object.

All free blocks are placed on the master freelist. All other freelists are zeroed.

If the object has multiple freelist groups, then the free blocks are distributed among all freelists, allocating to the different groups in round-robin fashion.

Syntax

```
DBMS_REPAIR.REBUILD_FREELISTS (
   schema_name    IN VARCHAR2,
   object_name    IN  VARCHAR2,
   partition_name IN VARCHAR2 DEFAULT NULL,
   object_type    IN BINARY_INTEGER DEFAULT TABLE_OBJECT);
```

Parameters

Table 146-9 REBUILD_FREELISTS Procedure Parameters

Parameter	Description
`schema_name`	Schema name.
`object_name`	Name of the object whose freelists are to be rebuilt.

Table 146-9 (Cont.) REBUILD_FREELISTS Procedure Parameters

Parameter	Description
partition_name	Partition or subpartition name whose freelists are to be rebuilt. If this is a partitioned object, and partition_name is not specified, then all partitions and subpartitions are processed. If this is a partitioned object, and the specified partition contains subpartitions, then all subpartitions are processed.
object_type	Type of the object to be processed. This must be either TABLE_OBJECT (default) or INDEX_OBJECT. See"Constants".

146.7.7 SEGMENT_FIX_STATUS Procedure

With this procedure you can fix the corrupted state of a bitmap entry. The procedure either recalculates the state based on the current contents of the corresponding block or sets the state to a specific value.

Syntax

```
DBMS_REPAIR.SEGMENT_FIX_STATUS (
   segment_owner   IN VARCHAR2,
   segment_name    IN VARCHAR2,
   segment_type    IN BINARY_INTEGER DEFAULT TABLE_OBJECT,
   file_number     IN BINARY_INTEGER DEFAULT NULL,
   block_number    IN BINARY_INTEGER DEFAULT NULL,
   status_value    IN BINARY_INTEGER DEFAULT NULL,
   partition_name  IN VARCHAR2 DEFAULT NULL,);
```

Parameters

Table 146-10 SEGMENT_FIX_STATUS Procedure Parameters

Parameter	Description
schema_owner	Schema name of the segment.
segment_name	Segment name.
partition_name	Optional. Name of an individual partition. NULL for nonpartitioned objects. Default is NULL.
segment_type	Optional Type of the segment (for example, TABLE_OBJECT or INDEX_OBJECT). Default is NULL.
file_number	(optional) The tablespace-relative file number of the data block whose status has to be fixed. If omitted, all the blocks in the segment will be checked for state correctness and fixed.
block_number	(optional) The file-relative block number of the data block whose status has to be fixed. If omitted, all the blocks in the segment will be checked for state correctness and fixed.

Table 146-10 (Cont.) SEGMENT_FIX_STATUS Procedure Parameters

Parameter	Description
`status_value`	(optional) The value to which the block status described by the `file_number` and `block_number` will be set. If omitted, the status will be set based on the current state of the block. This is almost always the case, but if there is a bug in the calculation algorithm, the value can be set manually. Status values: • 1 = block is full • 2 = block is 0-25% free • 3 = block is 25-50% free • 4 = block is 50-75% free • 5 = block is 75-100% free The status for bitmap blocks, segment headers, and extent map blocks cannot be altered. The status for blocks in a fixed hash area cannot be altered. For index blocks, there are only two possible states: 1 = block is full and 3 = block has free space.

146.7.8 SKIP_CORRUPT_BLOCKS Procedure

This procedure enables or disables the skipping of corrupt blocks during index and table scans of the specified object.

When the object is a table, skip applies to the table and its indexes. When the object is a cluster, it applies to all of the tables in the cluster, and their respective indexes.

> **Note:**
>
> When Oracle performs an index range scan on a corrupt index after DBMS_REPAIR.SKIP_CORRUPT_BLOCKS has been set for the base table, corrupt branch blocks and root blocks are not skipped. Only corrupt non-root leaf blocks are skipped.

Syntax

```
DBMS_REPAIR.SKIP_CORRUPT_BLOCKS (
   schema_name  IN VARCHAR2,
   object_name  IN VARCHAR2,
   object_type  IN BINARY_INTEGER DEFAULT TABLE_OBJECT,
   flags        IN BINARY_INTEGER DEFAULT SKIP_FLAG);
```

Parameters

Table 146-11 SKIP_CORRUPT_BLOCKS Procedure Parameters

Parameter	Description
`schema_name`	Schema name of the object to be processed.
`object_name`	Name of the object.

Table 146-11 (Cont.) SKIP_CORRUPT_BLOCKS Procedure Parameters

Parameter	Description
`object_type`	Type of the object to be processed. This must be either `TABLE_OBJECT` (default) or `CLUSTER_OBJECT`. See "Constants".
`flags`	If `SKIP_FLAG` is specified, then it turns on the skip of software corrupt blocks for the object during index and table scans. If `NOSKIP_FLAG` is specified, then scans that encounter software corrupt blocks return an `ORA-1578`. See"Constants".

147
DBMS_RESCONFIG

The DBMS_RESCONFIG package provides an interface to operate on the resource configuration list, and to retrieve listener information for a resource.

This chapter contains the following topics:

- Overview
- Summary of DBMS_RESCONFIG Subprograms

> **See Also:**
>
> *Oracle XML DB Developer's Guide* for more information about "Resource Configuration".

147.1 DBMS_RESCONFIG Overview

The DBMS_RESCONFIG package contains functions and procedures to manage the resource configuration lists of individual resources and the repository.

147.2 Summary of DBMS_RESCONFIG Subprograms

This table lists and briefly describes the DBMS_RESCONFIG package subprograms.

Table 147-1 DBMS_RESCONFIG Package Subprograms

Subprogram	Description
ADDREPOSITORYRESCONFIG Procedure	Inserts the resource configuration specified by absolute path at the given position of the repository's configuration list
ADDRESCONFIG Procedure	Inserts the resource configuration specified by the absolute path at the given position in the target resource's configuration list
APPENDRESCONFIG Procedure	Appends the resource configuration specified by rcpath to the target resource's configuration list if it is not already included in the list
DELETEREPOSITORYRESCONFIG Procedure	Removes the configuration at the given position in the repository's configuration list.
DELETERESCONFIG Procedures	Removes the configuration at the given position in the target resource's configuration list. I
GETLISTENERS Function	Returns the list of listeners applicable for a given resource
GETREPOSITORYRESCONFIG Function	Returns the resource configuration at the specified position of the repository's configuration list

Table 147-1 (Cont.) DBMS_RESCONFIG Package Subprograms

Subprogram	Description
GETREPOSITORYRESCONFIGPATHS Function	Returns a list of resource configuration paths defined for the repository
GETRESCONFIG Function	Returns the resource configuration at the specified position of the target resource's configuration list
GETRESCONFIGPATHS Function	Returns a list of resource configuration paths defined in the target resource's configuration list
PATCHREPOSITORYRESCONFIGLIST Procedure	Removes invalid references from the repository resource configuration list, and makes the repository available

147.2.1 ADDREPOSITORYRESCONFIG Procedure

This procedure inserts the resource configuration specified by absolute path of the resource configuration at the specified position of the repository's configuration list. It shifts the element currently at that position (if any) and any subsequent elements to the right.

Syntax

```
DBMS_RESCONFIG.ADDREPOSITORYRESCONFIG(
   rcpath     IN   VARCHAR2,
   pos        IN   PLS_INTEGER := NULL);
```

Parameters

Table 147-2 ADDREPOSITORYRESCONFIG Function Parameters

Parameter	Description
`rcpath`	Absolute path of the resource configuration to be inserted. An exception is raised if `rcpath` already exists in the target's configuration list.
`pos`	Index at which the new configuration is to be inserted. If this parameter is not specified then the new configuration is appended to the end of the list. An exception is raised if the index is out of range (`pos` < 0 or `pos` > the size of the target resource's configuration list).

Usage Notes

- An error is raised if the document referenced by `rcpath` is not based on `XDBResConfig.xsd` schema.
- Users must have `XDBADMIN` role and `READ` privilege on the resource configuration to be inserted; otherwise, an error is returned.

147.2.2 ADDRESCONFIG Procedure

This procedure inserts the resource configuration specified by the absolute path of the resource configuration at the given position in the target resource's configuration list. It

shifts the element currently at that position (if any) and any subsequent elements to the right.

Syntax

```
DBMS_RESCONFIG.ADDRESCONFIG(
   respath    IN   VARCHAR2,
   rcpath     IN   VARCHAR2,
   pos        IN   PLS_INTEGER := NULL);
```

Parameters

Table 147-3 ADDRESCONFIG Function Parameters

Parameter	Description
`respath`	Absolute path of the target resource
`rcpath`	Absolute path of the resource configuration to be inserted. An exception is raised if rcpath already exists in the target's configuration list.
`pos`	Index at which the new configuration is to be inserted. If this parameter is not specified then the new configuration is appended to the end of the list. An exception is raised if the index is out of range (`pos` < 0 or `pos` > the size of the target resource's configuration list).

Usage Notes

- An error is raised if the document referenced by `rcpath` is not based on `XDBResConfig.xsd` schema.
- Users must have `WRITE-CONFIG` privilege on the target resource and read privilege on the resource configuration to be inserted; otherwise, an error is returned.

147.2.3 APPENDRESCONFIG Procedure

This procedure appends the resource configuration specified by rcpath to the target resource's configuration list if it is not already included in the list.

Syntax

```
DBMS_RESCONFIG.ADDRESCONFIG(
   respath       IN   VARCHAR2,
   rcpath        IN   VARCHAR2,
   appendOption  IN   PLS_INTEGER);
```

Parameters

Table 147-4 ADDRESCONFIG Function Parameters

Parameter	Description
respath	Absolute path of the target resource
`rcpath`	Absolute path of the resource configuration to be appended at the end of the target's configuration list. If `rcpath` already exists in the list then nothing is appended.

Table 147-4 (Cont.) ADDRESCONFIG Function Parameters

Parameter	Description
appendOption	Either APPEND_RESOURCE or APPEND_RECURSIVE. If APPEND_RESOURCE is specified then only the target resource is affected. If APPEND_RECURSIVE is specified then the target resource and all its descendents will be affected.

Usage Notes

- An error is raised if the document referenced by rcpath is not based on XDBResConfig.xsd schema.
- Users must have WRITE-CONFIG privilege on all affected resources and required read privilege on the resource configuration to be inserted; otherwise, an error is returned.

147.2.4 DELETEREPOSITORYRESCONFIG Procedure

This procedure removes the configuration at the given position in the repository's configuration list. It shifts any subsequent elements to the left.

Syntax

```
DBMS_RESCONFIG.DELETEREPOSITORYRESCONFIG(
   pos           IN   PLS_INTEGER);
```

Parameters

Table 147-5 DELETEREPOSITORYRESCONFIG Function Parameters

Parameter	Description
pos	The index of the configuration to be removed. An exception is raised if the index is out of range (pos < 0 or pos >= the size of the target resource's configuration list).

Usage Notes

- Users must have XDBADMIN role to execute this.
- This statement is treated as if it is a DDL statement. This means the system will implicitly commit before and after this statement.

147.2.5 DELETERESCONFIG Procedures

This procedure removes the configuration at the given position in the target resource's configuration list. It shifts any subsequent elements to the left. Users can use the overloaded for recursive deletion.

Syntax

```
DBMS_RESCONFIG.DELETERESCONFIG(
   respath       IN   VARCHAR2,
   pos           IN   PLS_INTEGER);
```

```
DBMS_RESCONFIG.DELETERESCONFIG(
   respath        IN  VARCHAR2,
   rcpath         IN  VARCHAR2,
   deleteOption   IN  PLS_INTEGER);
```

Parameters

Table 147-6 DELETERESCONFIG Procedure Parameters

Parameter	Description
respath	Absolute path of the target resource
pos	The index of the configuration to be removed. An exception is raised if the index is out of range (pos < 0 or pos >= the size of the target resource's configuration list).
rcpath	Absolute path of the resource configuration to be deleted if found in list.
deleteOption	Either DELETE_RESOURCE or DELETE_RECURSIVE. If DELETE_RESOURCE is specified then only the configuration list of the target resource is affected. If DELETE_RECURSIVE is specified then the configuration list of the target resource and all its descendents will be affected.

Usage Notes

Users must have WRITE-CONFIG privilege on the target resource to execute this.

147.2.6 GETLISTENERS Function

This function returns the list of listeners applicable for a given resource.

The value returned by this function is an XML document containing the <event-listeners> element of the XDBResconfig.xsd schema. It contains all the listeners applicable to the target resource, including repository-level listeners. From the returned XML document users can use the EXTRACT operator to retrieve the listeners defined for a specific event.

Syntax

```
DBMS_RESCONFIG.GETLISTENERS(
   path    IN   VARCHAR2)
 RETURN XMLTYPE;
```

Parameters

Table 147-7 GETLISTENERS Function Parameters

Parameter	Description
path	Absolute path of the target resource

Usage Notes

Users must have the required access privilege on all resource configurations referenced by the repository and the target resource; otherwise, an error is returned.

147.2.7 GETREPOSITORYRESCONFIG Function

This function returns the resource configuration at the specified position of the repository's configuration list.

Syntax

```
DBMS_RESCONFIG.GETREPOSITORYRESCONFIG(
   pos    IN   PLS_INTEGER)
 RETURN XMLTYPE;
```

Parameters

Table 147-8 GETREPOSITORYRESCONFIG Function Parameters

Parameter	Description
pos	Index of element to return. An exception is raised if the index is out of range (pos < 0 or pos >= the size of the repository's configuration list).

Usage Notes

Users must have the required read privilege on the requested resource configuration; otherwise, an error is returned.

147.2.8 GETREPOSITORYRESCONFIGPATHS Function

This function returns a list of resource configuration paths defined for the repository.

Syntax

```
DBMS_RESCONFIG.GETREPOSITORYRESCONFIGPATHS
 RETURN XDB$STRING_LIST_T;
```

Usage Notes

Users must be able to access all the referenced resource configurations; otherwise, an error is returned.

147.2.9 GETRESCONFIG Function

This function returns the resource configuration at the specified position of the target resource's configuration list.

Syntax

```
DBMS_RESCONFIG.GETRESCONFIG(
   respath IN VARCHAR2,
   pos IN PLS_INTEGER)
 RETURN XMLTYPE;
```

Parameters

Table 147-9 GETRESCONFIG Function Parameters

Parameter	Description
`respath`	Absolute path of the target resource
`pos`	Index of element to return. An exception is raised if the index is out of range (`pos` < 0 or `pos` >= the size of the target resource's configuration list).

Usage Notes

Users must have the required read privilege on the requested resource configuration; otherwise, an error is returned.

147.2.10 GETRESCONFIGPATHS Function

This function returns a list of resource configuration paths defined in the target resource's configuration list.

Syntax

```
DBMS_RESCONFIG.GETRESCONFIGPATHS(
   respath IN VARCHAR2)
 RETURN XDB$STRING_LIST_T;
```

Parameters

Table 147-10 GETRESCONFIGPATHS Function Parameters

Parameter	Description
`respath`	Absolute path of the target resource

Usage Notes

Users must be able to access all the referenced resource configurations; otherwise, an error is returned.

147.2.11 PATCHREPOSITORYRESCONFIGLIST Procedure

This procedure removes invalid references from the repository resource configuration list, and makes the repository available.

Under normal circumstances, deletion of a resource configuration resource cannot be performed if it is part of the repository resource configuration list. If, for some reason, the deletion of a resource configuration resource that is part of the repository resource configuration list succeeds, then any repository operation results in a 'dangling reference' error. This procedure removes those invalid references.

This procedure must be run as `SYS`.

Syntax

```
DBMS_RESCONFIG.PATCHREPOSITORYRESCONFIGLIST;
```

148
DBMS_RESOURCE_MANAGER

The DBMS_RESOURCE_MANAGER package maintains plans, consumer groups, and plan directives. It also provides semantics so that you may group together changes to the plan schema.

This chapter contains the following topics:

- Deprecated Subprograms
- Security Model
- Constants
- Summary of DBMS_RESOURCE_MANAGER Subprograms

> **See Also:**
>
> For more information on using the Database Resource Manager, see *Oracle Database Administrator's Guide*

148.1 DBMS_RESOURCE_MANAGER Deprecated Subprograms

The SET_INITIAL_CONSUMER_GROUP Procedure has been deprecated with Oracle Database 11*g*.

- SET_INITIAL_CONSUMER_GROUP Procedure

> **Note:**
>
> Oracle recommends that you do not use deprecated procedures in new applications. Support for deprecated features is for backward compatibility only.

148.2 DBMS_RESOURCE_MANAGER Security Model

The invoker must have the ADMINISTER_RESOURCE_MANAGER system privilege to execute these procedures.

The procedures to grant and revoke this privilege are in the package DBMS_RESOURCE_MANAGER_PRIVS.

148.3 DBMS_RESOURCE_MANAGER Constants

The DBMS_RESOURCE_MANAGER package defines several constants for specifying parameter values.

These are shown in the following table.

Table 148-1 DBMS_RESOURCE_MANAGER Constants

Constant	Type	Value	Description
CLIENT_ID	VARCHAR2(30)	CLIENT_ID	Client identifier of the session
CLIENT_MACHINE	VARCHAR2(30)	CLIENT_MACHINE	Name of the computer from which the client is making the connection
CLIENT_OS_USER	VARCHAR2(30)	CLIENT_OS_USER	Operating system user name of the client that is logging in
CLIENT_PROGRAM	VARCHAR2(30)	CLIENT_PROGRAM	Name of the client program used to log in to the server
MODULE_NAME	VARCHAR2(30)	MODULE_NAME	Module name in the currently running application as set by the SET_MODULE Procedure in the DBMS_APPLICATION_INFO package, or the equivalent OCI attribute setting
MODULE_NAME_ACTION	VARCHAR2(30)	MODULE_NAME_ACTION	A combination of the current module and the action being performed as set by either of the following procedures in the DBMS_APPLICATION_INFO package, or their equivalent OCI attribute setting: • SET_MODULE Procedure • SET_ACTION Procedure The attribute is specified as the module name followed by a period (.), followed by the action name (*module_name*.*action_name*).
ORACLE_FUNCTION	VARCHAR2(30)	ORACLE_FUNCTION	Function the session is currently executing. Valid functions are the BACKUP, COPY, DATALOAD, and INMEMORY. BACKUP is set for sessions that are doing backup operations using RMAN. COPY is set for sessions that are doing image copies using RMAN. DATALOAD is set for sessions that are loading data using Oracle Data Pump.
ORACLE_USER	VARCHAR2(30)	ORACLE_USER	Oracle Database user name

Table 148-1 (Cont.) DBMS_RESOURCE_MANAGER Constants

Constant	Type	Value	Description
SERVICE_MODULE	VARCHAR2(30)	SERVICE_MODULE	Combination of service and module names in this form: *service_name.module_name*
SERVICE_MODULE_ACTION	VARCHAR2(30)	SERVICE_MODULE_ACTION	Combination of service name, module name, and action name, in this form: *service_name.module_name.action_name*
SERVICE_NAME	VARCHAR2(30)	SERVICE_NAME	Service name used by the client to establish a connection

148.4 Summary of DBMS_RESOURCE_MANAGER Subprograms

This table lists the DBMS_RESOURCE_MANAGER subprograms and briefly describes them.

Table 148-2 DBMS_RESOURCE_MANAGER Package Subprograms

Subprogram	Description
BEGIN_SQL_BLOCK Procedure	Indicates the start of a block of SQL statements to be treated as a group by resource manager
CALIBRATE_IO Procedure	Calibrates the I/O capabilities of storage
CLEAR_PENDING_AREA Procedure	Clears the work area for the resource manager
CREATE_CATEGORY Procedure	Creates a new resource consumer group category
CREATE_CDB_PLAN Procedure	Creates entries which define consolidation resource plans.
CREATE_CDB_PLAN_DIRECTIVE Procedure	Creates the plan directives of the consolidation resource plan
CREATE_CDB_PROFILE_DIRECTIVE Procedure	Creates the performance profile directives of the consolidation resource plan
CREATE_CONSUMER_GROUP Procedure	Creates entries which define resource consumer groups
CREATE_PENDING_AREA Procedure	Creates a work area for changes to resource manager objects
CREATE_PLAN Procedure	Creates entries which define resource plans
CREATE_PLAN_DIRECTIVE Procedure	Creates resource plan directives
CREATE_SIMPLE_PLAN Procedure	Creates a single-level resource plan containing up to eight consumer groups in one step
DELETE_CATEGORY Procedure	Deletes an existing resource consumer group category
DELETE_CDB_PLAN Procedure	Deletes the consolidation resource plan
DELETE_CDB_PLAN_DIRECTIVE Procedure	Deletes the plan directive of the consolidation resource plan

Table 148-2 (Cont.) DBMS_RESOURCE_MANAGER Package Subprograms

Subprogram	Description
DELETE_CDB_PROFILE_DIRECTIVE Procedure	Deletes the performance profile directive of the consolidation resource plan
DELETE_CONSUMER_GROUP Procedure	Deletes entries which define resource consumer groups
DELETE_PLAN Procedure	Deletes the specified plan as well as all the plan directives it refers to
DELETE_PLAN_CASCADE Procedure	Deletes the specified plan as well as all its descendants (plan directives, subplans, consumer groups)
DELETE_PLAN_DIRECTIVE Procedure	Deletes resource plan directives
DEQUEUE_PARALLEL_STATEMENT Procedure	Dequeues a parallel statement from the parallel statement queue
END_SQL_BLOCK Procedure	Indicates the end of a block of SQL statements that should be treated as a group by resource manager
SET_CONSUMER_GROUP_MAPPING Procedure	Adds, deletes, or modifies entries for the login and run-time attribute mappings
SET_CONSUMER_GROUP_MAPPING_PRI Procedure	Creates the session attribute mapping priority list
SET_INITIAL_CONSUMER_GROUP Procedure	Assigns the initial resource consumer group for a user (Caution: Deprecated Subprogram)
SUBMIT_PENDING_AREA Procedure	Submits pending changes for the resource manager
SWITCH_CONSUMER_GROUP_FOR_SESS Procedure	Changes the resource consumer group of a specific session
SWITCH_CONSUMER_GROUP_FOR_USER Procedure	Changes the resource consumer group for all sessions with a given user name
SWITCH_PLAN Procedure	Sets the current resource manager plan
UPDATE_CATEGORY Procedure	Updates an existing resource consumer group category
UPDATE_CDB_AUTOTASK_DIRECTIVE Procedure	Updates the plan directives with regard to automated maintenance tasks
UPDATE_CDB_DEFAULT_DIRECTIVE Procedure	Updates the default values for a consolidation plan
UPDATE_CDB_PLAN Procedure	Updates the consolidation resource plan
UPDATE_CDB_PLAN_DIRECTIVE Procedure	Updates the plan directives for a consolidation resource plan
UPDATE_CDB_PROFILE_DIRECTIVE Procedure	Updates the performance profile directives of the consolidation resource plan
UPDATE_CONSUMER_GROUP Procedure	Updates entries which define resource consumer groups
UPDATE_PLAN Procedure	Updates entries which define resource plans
UPDATE_PLAN_DIRECTIVE Procedure	Updates resource plan directives
VALIDATE_PENDING_AREA Procedure	Validates pending changes for the resource manager

148.4.1 BEGIN_SQL_BLOCK Procedure

This procedure, to be used with parallel statement queuing, indicates the start of a block of SQL statements that should be treated as a group by resource manager.

Syntax

```
DBMS_RESOURCE_MANAGER.BEGIN_SQL_BLOCK;
```

Usage Notes

For more information, see "Parallel Statement Queuing" and "Managing Parallel Statement Queuing with Resource Manager" in *Oracle Database VLDB and Partitioning Guide*.

148.4.2 CALIBRATE_IO Procedure

This procedure calibrates the I/O capabilities of storage. Calibration status is available from the `V$IO_CALIBRATION_STATUS` view and results for a successful calibration run are located in `DBA_RSRC_IO_CALIBRATE` table.

Syntax

```
DBMS_RESOURCE_MANAGER.CALIBRATE_IO (
   num_physical_disks      IN  PLS_INTEGER DEFAULT 1,
   max_latency             IN  PLS_INTEGER DEFAULT 20,
   max_iops                OUT PLS_INTEGER,
   max_mbps                OUT PLS_INTEGER,
   actual_latency          OUT PLS_INTEGER);
```

Parameters

Table 148-3 CALIBRATE_IO Procedure Parameters

Parameter	Description
`num_physical_disks`	Approximate number of physical disks in the database storage. This parameter is used to determine the initial I/O load for the calibration run.
`max_latency`	Maximum tolerable latency in milliseconds for database-block-sized IO requests
`max_iops`	Maximum number of I/O requests per second that can be sustained. The I/O requests are randomly-distributed, database-block-sized reads.
`max_mbps`	Maximum throughput of I/O that can be sustained, expressed in megabytes per second. The I/O requests are randomly-distributed, 1 megabyte reads.
`actual_latency`	Average latency of database-block-sized I/O requests at `max_iops` rate, expressed in milliseconds

Usage Notes

- Only users with the SYSDBA privilege can run this procedure. Qualified users must also turn on `timed_statistics`, and ensure `asynch_io` is enabled for datafiles. This can be

achieved by setting `filesystemio_options` to either `ASYNCH` or `SETALL`. One can also query the `asynch_io` status by means of the following SQL statement:

```
col name format a50
SELECT name, asynch_io FROM v$datafile f,v$iostat_file i
  WHERE f.file#        = i.file_no
  AND   filetype_name  = 'Data File'
 /
```

- Only one calibration can be run at a time. If another calibration is initiated at the same time, it will fail.
- For an Oracle Real Application Clusters (Oracle RAC) database, the workload is simultaneously generated from all instances.
- In a multitenant container database (CDB), calibration can only be run from the CDB root (`CDB$ROOT`).
- Calibration is extremely disruptive to the database performance. It is strongly recommended to run calibration only when database users can tolerate severe deterioration to database performance.
- For optimal calibration results, no other database workloads should be running.

> **See Also:**
>
> *Oracle Database Performance Tuning Guide* for more information about calibration

Examples

Example of using I/O Calibration procedure

```
SET SERVEROUTPUT ON
DECLARE
  lat  NUMBER;
  iops INTEGER;
  mbps INTEGER;
BEGIN
-- DBMS_RESOURCE_MANAGER.CALIBRATE_IO (<DISKS>, <MAX_LATENCY>, iops, mbps, lat);
   DBMS_RESOURCE_MANAGER.CALIBRATE_IO (2, 10, iops, mbps, lat);

end;
/
```

View for I/O calibration results

```
SQL> desc V$IO_CALIBRATION_STATUS
  Name                                      Null?    Type
  ----------------------------------------- -------- ----------------------------
  STATUS                                             VARCHAR2(13)
  CALIBRATION_TIME                                   TIMESTAMP(3)

SQL> desc gv$io_calibration_status
  Name                                      Null?    Type
  ----------------------------------------- -------- ----------------------------
  INST_ID                                            NUMBER
  STATUS                                             VARCHAR2(13)
  CALIBRATION_TIME                                   TIMESTAMP(3)
```

```
Column explanation:
-------------------
STATUS:
  IN PROGRESS   : Calibration in Progress (Results from previous calibration
                  run displayed, if available)
  READY         : Results ready and available from earlier run
  NOT AVAILABLE : Calibration results not available.

CALIBRATION_TIME: End time of the last calibration run
```

DBA table that stores I/O Calibration results

```
SQL> desc DBA_RSRC_IO_CALIBRATE
  Name                                      Null?    Type
  ----------------------------------------- -------- ----------------------------
  START_TIME                                         TIMESTAMP(6)
  END_TIME                                           TIMESTAMP(6)
  MAX_IOPS                                           NUMBER
  MAX_MBPS                                           NUMBER
  MAX_PMBPS                                          NUMBER
  LATENCY                                            NUMBER

/
```

148.4.3 CLEAR_PENDING_AREA Procedure

This procedure clears pending changes for the resource manager.

Syntax

```
DBMS_RESOURCE_MANAGER.CLEAR_PENDING_AREA;
```

148.4.4 CREATE_CATEGORY Procedure

This procedure creates a new consumer group category. The primary purpose of this attribute is to support Exadata I/O Resource Manager category plans.

The view DBA_RSRC_CATEGORIES defines the currently defined categories. The ADMINISTRATIVE, INTERACTIVE, BATCH, MAINTENANCE, and OTHER categories are available.

Syntax

```
DBMS_RESOURCE_MANAGER.CREATE_CATEGORY (
   category    IN    VARCHAR2,
   comment     IN    VARCHAR2 DEFAULT NULL);
```

Parameters

Table 148-4 CREATE_CATEGORY Procedure Parameters

Parameter	Description
category	Name of consumer group category
comment	User comment

148.4.5 CREATE_CDB_PLAN Procedure

Creates entries which define consolidation resource plans.

Syntax

```
DBMS_RESOURCE_MANAGER.CREATE_CDB_PLAN (
   plan                    IN    VARCHAR2(32),
   comment                 IN    VARCHAR2(2000) DEFAULT NULL);
```

Parameters

Table 148-5 CREATE_CDB_PLAN Procedure Parameters

Parameter	Description
plan	Name of the consolidation plan
comment	User comment

Usage Notes

This procedure can be run only from the CDB root (CDB$ROOT).

148.4.6 CREATE_CDB_PLAN_DIRECTIVE Procedure

This procedure creates the plan directives of the consolidation resource plan. Plan directives specify the resource allocation policy for pluggable databases (PDBs).

Syntax

```
DBMS_RESOURCE_MANAGER.CREATE_CDB_PLAN_DIRECTIVE (
   plan                   IN    VARCHAR2,
   pluggable_database     IN    VARCHAR2,
   comment                IN    VARCHAR2 (2000) DEFAULT '',
   shares                 IN    NUMBER          DEFAULT NULL,
   utilization_limit      IN    NUMBER          DEFAULT NULL,
   parallel_server_limit  IN    NUMBER          DEFAULT NULL,
   memory_limit           IN    NUMBER          DEFAULT 100,
   memory_min             IN    NUMBER          DEFAULT 0);
```

Parameters

Table 148-6 CREATE_CDB_PLAN_DIRECTIVE Procedure Parameters

Parameter	Description
`plan`	Name of the consolidation plan
`pluggable_database`	Name of the PDB
`comment`	User comment
`shares`	Specifies the share of resource allocation for the PDB. CPU Resource Manager and Exadata I/O Resource Manager are enabled by specifying shares for each PDB. The `shares` parameter is also used for Parallel Statement Queuing. If no share is specified, the default is obtained from the default directive, specified through UPDATE_CDB_DEFAULT_DIRECTIVE Procedure.
`utilization_limit`	Specifies the maximum percentage of the CDB's CPU and Exadata I/O resources that the PDB can utilize. CPU Resource Manager and Exadata I/O Resource Manager can also be limited by setting the `CPU_COUNT` parameter for the PDB.

Table 148-6 (Cont.) CREATE_CDB_PLAN_DIRECTIVE Procedure Parameters

Parameter	Description
parallel_server_limit	Parallel servers that the PDB can use after which parallel statements are queued. Alternatively, you can set the parallel_servers_target at the PDB level. A PDB can set a lower limit for parallel execution servers than the limit specified in the CDB resource plan. When the PARALLEL_SERVERS_TARGET initialization parameter is set in a PDB, and parallel execution server limit is specified for a PDB in the CDB resource plan, then the lower limit is used. For example, assume that the parallel_servers_target initialization parameter is set to 100 in the CDB root and parallel_server_limit is set to 70 for hrpdb in the CDB resource plan. Also, assume that hrpdb has its parallel_servers_target initialization parameter set to 50. In this case, the limit for parallel execution servers for hrpdb is 50, because 50 is lower than the CDB resource plan limit of 70 for hrpdb. **Note:** Oracle recommends, that you use parallel_servers_target parameter instead of parallel_servers_limit in a CDB resource plan.
memory_limit	This parameter is only applicable to Oracle Exadata storage for configuring the Exadata Smart Flash Cache and Exadata PMEM Cache.
memory_min	This parameter is only applicable to Oracle Exadata storage for configuring the Exadata Smart Flash Cache and Exadata PMEM Cache.

Usage Notes

- The default value for shares, utilization_limit, and parallel_server_limit is NULL. When a user specifies NULL, or does not specify a value, this indicates that the default value should be used.
- This procedure can be run only from the CDB root (CDB$ROOT).

148.4.7 CREATE_CDB_PROFILE_DIRECTIVE Procedure

This procedure creates the performance profile directives of the consolidation resource plan. The directives specify the resource allocation policy for pluggable databases (PDBs) that use the performance profile.

For a PDB to use the new performance profile, the PDB must have the DB_PERFORMANCE_PROFILE initialization parameter set to the profile name.

This procedure provides an easy way to specify the directive for a large number of PDBs with the same resource requirements. Each PDB with a DB_PERFORMANCE_PROFILE initialization parameter set to the performance profile name inherits the settings specified by this directive, including the shares, utilization limit, and so on.

Syntax

```
DBMS_RESOURCE_MANAGER.CREATE_CDB_PROFILE_DIRECTIVE (
   plan                   IN    VARCHAR2,
   profile                IN    VARCHAR2,
   comment                IN    VARCHAR2 (2000) DEFAULT '',
   shares                 IN    NUMBER          DEFAULT NULL,
   utilization_limit      IN    NUMBER          DEFAULT NULL,
   parallel_server_limit  IN    NUMBER          DEFAULT NULL,
   memory_limit           IN    NUMBER          DEFAULT 100,
   memory_min             IN    NUMBER          DEFAULT 0);
```

Parameters

Table 148-7 CREATE_CDB_PROFILE_DIRECTIVE Procedure Parameters

Parameter	Description
plan	Name of the consolidation plan
profile	Name of the performance profile
comment	User comment
shares	Specifies the share of resource allocation for PDBs that use the performance profile. CPU Resource Manager and Exadata I/O Resource Manager are enabled by specifying shares for each PDB. The shares parameter is also used for Parallel Statement Queuing. If no share is specified, the default is obtained from the default directive, specified through UPDATE_CDB_DEFAULT_DIRECTIVE Procedure.
utilization_limit	Specifies the maximum percentage of CPU Resource Manager and Exadata I/O Resource Manager that PDBs that use the performance profile can utilize.
parallel_server_limit	Specifies the maximum percentage of parallel_servers_target parallel servers that PDBs that use the performance profile can use.
memory_limit	This parameter is only applicable to Oracle Exadata storage for configuring the Exadata Smart Flash Cache and Exadata PMEM Cache.
memory_min	This parameter is only applicable to Oracle Exadata storage for configuring the Exadata Smart Flash Cache and Exadata PMEM Cache.

148.4.8 CREATE_CONSUMER_GROUP Procedure

This procedure creates entries which define resource consumer groups.

Syntax

```
DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP (
   consumer_group  IN VARCHAR2,
   comment         IN VARCHAR2 DEFAULT NULL,
```

```
   cpu_mth         IN VARCHAR2 DEFAULT NULL,
   mgmt_mth        IN VARCHAR2 DEFAULT 'ROUND-ROBIN',
   category        IN VARCHAR2 DEFAULT 'OTHER');
```

Parameters

Table 148-8 CREATE_CONSUMER_GROUP Procedure Parameters

Parameter	Description
`consumer_group`	Name of the consumer group
`comment`	User comment
`cpu_mth`	Name of CPU resource allocation method (deprecated)
`mgmt_mth`	Name of CPU resource allocation method
`category`	Describes the category of the consumer group. The primary purpose of this attribute is to support Exadata I/O Resource Manager category plans. The view `DBA_RSRC_CATEGORIES` defines the currently defined categories. Categories can be modified, using the CREATE_CATEGORY Procedure, UPDATE_CATEGORY Procedure, and DELETE_CATEGORY Procedure.

148.4.9 CREATE_PENDING_AREA Procedure

This procedure makes changes to resource manager objects.

All changes to the plan schema must be done within a pending area. The pending area can be thought of as a "scratch" area for plan schema changes. The administrator creates this pending area, makes changes as necessary, possibly validates these changes, and only when the submit is completed do these changes become active.

Syntax

```
DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA;
```

Usage Notes

You may, at any time while the pending area is active, view the current plan schema with your changes by selecting from the appropriate user views.

At any time, you may clear the pending area if you want to stop the current changes. You may also call the `VALIDATE` procedure to confirm whether the changes you have made are valid. You do not have to perform your changes in a given order to maintain a consistent group of entries. These checks are also implicitly done when the pending area is submitted.

> **Note:**
>
> Oracle allows "orphan" consumer groups (in other words, consumer groups that have no plan directives that refer to them). This is in anticipation that an administrator may want to create a consumer group that is not currently being used, but will be used in the future.

For resource plans, the following rules must be adhered to, and they are checked whenever the validate or submit procedures are executed:

- No plan schema may contain any loops.
- All plans and consumer groups referred to by plan directives must exist.
- All plans must have plan directives that refer to either plans or consumer groups.
- All percentages in any given level must not add up to greater than 100 for the emphasis resource allocation method.
- No plan may be deleted that is currently being used as a top plan by an active instance.
- The plan directive parameter, `parallel_degree_limit_p1`, may only appear in plan directives that refer to consumer groups (that is, not at subplans).
- There cannot be more than 28 plan directives coming from any given plan (that is, no plan can have more than 28 children).
- There cannot be more than 28 consumer groups in any active plan schema.
- Plans and consumer groups use the same namespace; therefore, no plan can have the same name as any consumer group.
- There must be a plan directive for `OTHER_GROUPS` somewhere in any active plan schema.This ensures that a session not covered by the currently active plan is allocated resources as specified by the `OTHER_GROUPS` directive.

> **Note:**
>
> These rules are not applicable for CDB resource plans.

If any of the preceding rules are broken when checked by the `VALIDATE` or `SUBMIT` procedures, then an informative error message is returned. You may then make changes to fix one or more problems and reissue the validate or submit procedures.

148.4.10 CREATE_PLAN Procedure

This procedure creates entries which define resource plans.

Syntax

```
DBMS_RESOURCE_MANAGER.CREATE_PLAN (
   plan                       IN   VARCHAR2,
   comment                    IN   VARCHAR2 DEFAULT NULL,
   cpu_mth                    IN   VARCHAR2 DEFAULT NULL, -- deprecated
   active_sess_pool_mth       IN   VARCHAR2 DEFAULT 'ACTIVE_SESS_POOL_ABSOLUTE',
   parallel_degree_limit_mth  IN   VARCHAR2 DEFAULT
                                      'PARALLEL_DEGREE_LIMIT_ABSOLUTE',
   queueing_mth               IN   VARCHAR2 DEFAULT 'FIFO_TIMEOUT',
   mgmt_mth                   IN   VARCHAR2 DEFAULT 'EMPHASIS',
   sub_plan                   IN   BOOLEAN DEFAULT FALSE,
   max_iops                   IN   NUMBER DEFAULT NULL,
   max_mbps                   IN   NUMBER DEFAULT NULL);
```

Parameters

Table 148-9 CREATE_PLAN Procedure Parameters

Parameter	Description
plan	Name of the resource plan
comment	User comment
cpu_mth	Allocation method for CPU resources (deprecated)
active_sess_pool_mth	Active session pool resource allocation method. Limits the number of active sessions. All other sessions are inactive and wait in a queue to be activated. ACTIVE_SESS_POOL_ABSOLUTE is the default and only method available.
parallel_degree_limit_mth	Resource allocation method for specifying a limit on the degree of parallelism of any operation. PARALLEL_DEGREE_LIMIT_ABSOLUTE is the default and only method available.
queueing_mth	Queuing resource allocation method. Controls order in which queued inactive sessions will execute. FIFO_TIMEOUT is the default and only method available
mgmt_mth	Resource allocation method for specifying how much resources (for example, CPU or I/O) each consumer group or sub-plan gets • EMPHASIS - for multilevel plans that use percentages to specify how I/O resources are distributed among consumer groups • RATIO - for single-level plans that use ratios to specify how I/O resources are distributed
sub_plan	If TRUE, indicates that this plan is only intended for use as a sub-plan. Sub-plans are not required to have an OTHER_GROUPS directive. Default is FALSE.
max_iops	Nonoperative
max_mbps	Nonoperative

Usage Notes

If you want to use any default resource allocation method, then you do not need to specify it when creating or updating a plan.

148.4.11 CREATE_PLAN_DIRECTIVE Procedure

This procedure creates resource plan directives.

> **Note:**
>
> The parameters max_utilization_limit and parallel_target_percentage are deprecated with Oracle Database 11*g* Release 1 (11.1.0.1), and are replaced by utilization_limit and parallel_server_limit.

Syntax

```
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (
   plan                          IN VARCHAR2,
   group_or_subplan              IN VARCHAR2,
   comment                       IN VARCHAR2 DEFAULT NULL,
   cpu_p1                        IN NUMBER   DEFAULT NULL, -- deprecated
   cpu_p2                        IN NUMBER   DEFAULT NULL, -- deprecated
   cpu_p3                        IN NUMBER   DEFAULT NULL, -- deprecated
   cpu_p4                        IN NUMBER   DEFAULT NULL, -- deprecated
   cpu_p5                        IN NUMBER   DEFAULT NULL, -- deprecated
   cpu_p6                        IN NUMBER   DEFAULT NULL, -- deprecated
   cpu_p7                        IN NUMBER   DEFAULT NULL, -- deprecated
   cpu_p8                        IN NUMBER   DEFAULT NULL, -- deprecated
   active_sess_pool_p1           IN NUMBER   DEFAULT NULL,
   queueing_p1                   IN NUMBER   DEFAULT NULL,
   parallel_degree_limit_p1      IN NUMBER   DEFAULT NULL,
   switch_group                  IN VARCHAR2 DEFAULT NULL,
   switch_time                   IN NUMBER   DEFAULT NULL,
   switch_estimate               IN BOOLEAN  DEFAULT FALSE,
   max_est_exec_time             IN NUMBER   DEFAULT NULL,
   undo_pool                     IN NUMBER   DEFAULT NULL,
   max_idle_time                 IN NUMBER   DEFAULT NULL,
   max_idle_blocker_time         IN NUMBER   DEFAULT NULL,
   switch_time_in_call           IN NUMBER   DEFAULT NULL, -- deprecated
   mgmt_p1                       IN NUMBER   DEFAULT NULL,
   mgmt_p2                       IN NUMBER   DEFAULT NULL,
   mgmt_p3                       IN NUMBER   DEFAULT NULL,
   mgmt_p4                       IN NUMBER   DEFAULT NULL,
   mgmt_p5                       IN NUMBER   DEFAULT NULL,
   mgmt_p6                       IN NUMBER   DEFAULT NULL,
   mgmt_p7                       IN NUMBER   DEFAULT NULL,
   mgmt_p8                       IN NUMBER   DEFAULT NULL,
   switch_io_megabytes           IN NUMBER   DEFAULT NULL,
   switch_io_reqs                IN NUMBER   DEFAULT NULL,
   switch_for_call               IN BOOLEAN  DEFAULT NULL,
   max_utilization_limit         IN NUMBER   DEFAULT NULL,  -- deprecated
   parallel_target_percentage    IN NUMBER   DEFAULT NULL,  -- deprecated
   parallel_server_limit         IN NUMBER   DEFAULT NULL,
   utilization_limit             IN NUMBER   DEFAULT NULL,
   switch_io_logical             IN NUMBER   DEFAULT NULL,
   switch_elapsed_time           IN NUMBER   DEFAULT NULL,
   shares                        IN NUMBER   DEFAULT NULL,
   parallel_stmt_critical        IN VARCHAR2 DEFAULT NULL,
   session_pga_limit             IN NUMBER   DEFAULT NULL,
   pq_timeout_action             IN NUMBER   DEFAULT NULL,
   parallel_queue_timeout        IN NUMBER   DEFAULT NULL,);
```

Note:

Oracle recommends that you use `shares` instead of `mgmt_p*`.

Parameters

Table 148-10 CREATE_PLAN_DIRECTIVE Procedure Parameters

Parameter	Description
plan	Name of the resource plan
group_or_subplan	Name of the consumer group or subplan
comment	Comment for the plan directive
cpu_p1	-- deprecated: use mgmt_p1 or, even better, shares instead
cpu_p2	-- deprecated: use mgmt_p2 or, even better, shares instead
cpu_p3	-- deprecated: use mgmt_p3 or, even better, shares instead
cpu_p4	-- deprecated: use mgmt_p4 or, even better, shares instead
cpu_p5	-- deprecated: use mgmt_p5 or, even better, shares instead
cpu_p6	-- deprecated: use mgmt_p6 or, even better, shares instead
cpu_p7	-- deprecated: use mgmt_p7 or, even better, shares instead
cpu_p8	-- deprecated: use mgmt_p8 or, even better, shares instead
active_sess_pool_p1	Specifies maximum number of sessions that can currently have an active call
queueing_p1	Specified time (in seconds) after which a call in the inactive session queue (waiting for execution) will time out. Default is NULL, which means unlimited.
parallel_degree_limit_p1	Specifies a limit on the degree of parallelism for any operation. Default is NULL, which means unlimited. If the value is 0, then all operations will be serial.
switch_group	Specifies consumer group to switch to, once a switch condition is met. If the group name is CANCEL_SQL, then the current call is canceled when the switch condition is met. If the group name is KILL_SESSION, then the session is killed when the switch condition is met. If the group name is LOG_ONLY, then no action is taken other than recording this event via SQL monitor.Default is NULL.
switch_time	Specifies the time on CPU (not elapsed time) that a session can execute before an action is taken. Default is NULL, which means unlimited. As with other switch directives, if switch_for_call is TRUE, the number of CPUs is accumulated from the start of a call. Otherwise, the number of CPUs is accumulated for the length of the session.
switch_estimate	If TRUE, tells Oracle to use its execution time estimate to automatically switch the consumer group of an operation before beginning its execution. This is used in conjunction with the switch_time directive. Default value is FALSE.
max_est_exec_time	Specifies the maximum execution time (in CPU seconds) allowed for a session. If the optimizer estimates that an operation will take longer than MAX_EST_EXEC_TIME, the operation is not started and ORA-07455 is issued. If the optimizer does not provide an estimate, this directive has no effect. Default is NULL, which means unlimited.

Table 148-10 (Cont.) CREATE_PLAN_DIRECTIVE Procedure Parameters

Parameter	Description
undo_pool	Limits the size in kilobytes of the undo records corresponding to uncommitted transactions by this consumer group
max_idle_time	Indicates the maximum session idle time. Default is NULL, which means unlimited.
max_idle_blocker_time	Maximum amount of time in seconds that a session can be idle while blocking another session's acquisition of a resource
switch_time_in_call	Deprecated. If this parameter is specified, switch_time is set to switch_time_in_call (in seconds) and switch_for_call is effectively set to TRUE. It is better to use switch_time and switch_for_call.
mgmt_p1	Resource allocation value for level 1 (replaces cpu_p1): • EMPHASIS - specifies the resource percentage at the first level • RATIO - specifies the weight of resource usage
mgmt_p2	Resource allocation value for level 2 (replaces cpu_p2) • EMPHASIS - specifies the resource percentage at the second level • RATIO - non-applicable
mgmt_p3	Resource allocation value for level 3 (replaces cpu_p3) • EMPHASIS - specifies the resource percentage at the third level • RATIO - non-applicable
mgmt_p4	Resource allocation value for level 4 (replaces cpu_p4) • EMPHASIS - specifies the resource percentage at the fourth level • RATIO - non-applicable
mgmt_p5	Resource allocation value for level 5 (replaces cpu_p5) • EMPHASIS - specifies the resource percentage at the fifth level • RATIO - non-applicable
mgmt_p6	Resource allocation value for level 6 (replaces cpu_p6) • EMPHASIS - specifies the resource percentage at the sixth level • RATIO - non-applicable
mgmt_p7	Resource allocation value for level 7 (replaces cpu_p7) • EMPHASIS - specifies the resource percentage at the seventh level • RATIO - non-applicable
mgmt_p8	Resource allocation value for level 8 (replaces cpu_p8) • EMPHASIS - specifies the resource percentage at the eighth level • RATIO - non-applicable

Table 148-10 (Cont.) CREATE_PLAN_DIRECTIVE Procedure Parameters

Parameter	Description
switch_io_megabytes	Specifies the amount of I/O (in MB) that a session can issue before an action is taken. Default is NULL, which means unlimited. As with other switch directives, if switch_for_call is TRUE, the number of CPUs is accumulated from the start of a call. Otherwise, the number of CPUs is accumulated for the length of the session.
switch_io_reqs	Specifies the number of I/O requests that a session can issue before an action is taken. Default is NULL, which means unlimited. As with other switch directives, if switch_for_call is TRUE, the number of CPUs is accumulated from the start of a call. Otherwise, the number of CPUs is accumulated for the length of the session.
switch_for_call	Specifies that if an action is taken because of the switch_time, switch_io_megabytes, switch_io_reqs, switch_io_logical or switch_elapsed_time parameters, the consumer group is restored to its original consumer group at the end of the top call. Default is NULL, which means that the original consumer group is not restored at the end of the top call.
max_utilization_limit	-- deprecated: use utilization_limit instead
parallel_target_percentage	-- deprecated: use parallel_sever_limit instead
parallel_queue_timeout	Specifies the time (in seconds) that a parallel statement may remain in its Consumer Group's parallel statement queue before it is removed and terminated with an error (ORA- 07454). **Note:** You can use the pq_timeout_action parameter to specify the action to be taken when a parallel statement is removed from the queue.
parallel_sever_limit	Specifies the maximum percentage of parallel_servers_target parallel servers that the Consumer Group can use, after which parallel statements are queued.
utilization_limit	Resource limit. Currently it includes CPU and I/O for Exadata. For CPU, this limits the CPU utilization for the consumer group. For Exadata I/O, this limits the disk utilization for the consumer group. This does not apply to parallel servers.
switch_io_logical	Number of logical IOs that will trigger the action specified by switch_group. As with other switch directives, if switch_for_call is TRUE, the number of logical IOs is accumulated from the start of a call. Otherwise, the number of logical IOs is accumulated for the length of the session.

Table 148-10 (Cont.) CREATE_PLAN_DIRECTIVE Procedure Parameters

Parameter	Description
switch_elapsed_time	Elapsed time that will trigger the action specified by switch_group. As with other switch directives, if switch_for_call is TRUE, the elapsed time is accumulated from the start of a call. Otherwise, the elapsed time is accumulated for the length of the session.
shares	Specifies the share of resource allocation for the consumer group. CPU Resource Manager and Exadata I/O Resource Manager are enabled by specifying shares for each consumer group. The shares parameter is also used for Parallel Statement Queuing. If CPU Resource Manager and Exadata I/O Resource Manager are enabled, then the default value is 1.
parallel_stmt_critical	If set to BYPASS_QUEUE, parallel statements from the Consumer Group are not queued, regardless of the PARALLEL_DEGREE_POLICY parameter value. If set to QUEUE, all the parallel statements from the consumer group, irrespective of the parallel_degree_policy parameter value, are eligible for queuing. Default is FALSE, which means that parallel statements are eligible for queuing, based on the parallel_degree_policy parameter value.
session_pga_limit	Maximum amount of untunable PGA (in MB) that a session in this consumer group can allocate before being terminated. NULL (default) indicates no limit. SQL operations that allocate tunable PGA (operations that can opt to use temp space) are not controlled by this limit.
pq_timeout_action	Specifies the action to be taken when a parallel statement is removed from the queue due to parallel_queue_timeout. The values are: • CANCEL — The parallel statement is terminated with error ORA-7454 • RUN — The SQL statement runs immediately, and might get downgraded if parallel servers are unavailable The default action of this parameter is CANCEL.

Usage Notes

- All parameters default to NULL.
- For max_idle_time and max_idle_blocker_time, PMON will check these limits once a minute. If it finds a session that has exceeded one of the limits, it will forcibly kill the session and clean up all its state.
- The parameter switch_for_call is mostly useful for three-tier applications where the mid-tier server is implementing session pooling. By using switch_for_call, the resource usage of one client will not affect a future client that happens to be executed on the same session.
- An error is thrown if PQ_TIMEOUT_ACTION is specified, but PARALLEL_QUEUE_TIMEOUT is not specified.
- Specifies the action to be taken when a parallel statement is removed from the queue.

148.4.12 CREATE_SIMPLE_PLAN Procedure

This procedure creates a single-level resource plan containing up to eight consumer groups in one step. You do not need to create a pending area manually before creating a resource plan, or use the `CREATE_CONSUMER_GROUP` and `CREATE_RESOURCE_PLAN_DIRECTIVES` procedures separately.

Syntax

```
DBMS_RESOURCE_MANAGER.CREATE_SIMPLE_PLAN (
   simple_plan      IN  VARCHAR2  DEFAULT NULL,
   consumer_group1  IN  VARCHAR2  DEFAULT NULL,
   group1_cpu       IN  NUMBER    DEFAULT NULL,   -- deprecated
   consumer_group2  IN  VARCHAR2  DEFAULT NULL,
   group2_cpu       IN  NUMBER    DEFAULT NULL,   -- deprecated
   consumer_group3  IN  VARCHAR2  DEFAULT NULL,
   group3_cpu       IN  NUMBER    DEFAULT NULL,   -- deprecated
   consumer_group4  IN  VARCHAR2  DEFAULT NULL,
   group4_cpu       IN  NUMBER    DEFAULT NULL,   -- deprecated
   consumer_group5  IN  VARCHAR2  DEFAULT NULL,
   group5_cpu       IN  NUMBER    DEFAULT NULL,   -- deprecated
   consumer_group6  IN  VARCHAR2  DEFAULT NULL,
   group6_cpu       IN  NUMBER    DEFAULT NULL,   -- deprecated
   consumer_group7  IN  VARCHAR2  DEFAULT NULL,
   group7_cpu       IN  NUMBER    DEFAULT NULL,   -- deprecated
   consumer_group8  IN  VARCHAR2  DEFAULT NULL,
   group8_cpu       IN  NUMBER    DEFAULT NULL,   -- deprecated
   group1_percent   IN  NUMBER    DEFAULT NULL,
   group2_percent   IN  NUMBER    DEFAULT NULL,
   group3_percent   IN  NUMBER    DEFAULT NULL,
   group4_percent   IN  NUMBER    DEFAULT NULL,
   group5_percent   IN  NUMBER    DEFAULT NULL,
   group6_percent   IN  NUMBER    DEFAULT NULL,
   group7_percent   IN  NUMBER    DEFAULT NULL,
   group8_percent   IN  NUMBER    DEFAULT NULL);
```

Parameters

Table 148-11 CREATE_SIMPLE_PLAN Procedure Parameters

Parameter	Description
`simple_plan`	Name of the resource plan
`consumer_group1`	Name of the consumer group
`group1_cpu`	Percentage for group (deprecated)
`consumer_group2`	Name of the consumer group
`group2_cpu`	Percentage for group (deprecated)
`consumer_group3`	Name of the consumer group
`group3_cpu`	Percentage for group (deprecated)
`consumer_group4`	Name of the consumer group
`group4_cpu`	Percentage for group (deprecated)
`consumer_group5`	Name of the consumer group
`group5_cpu`	Percentage for group (deprecated)

Table 148-11 (Cont.) CREATE_SIMPLE_PLAN Procedure Parameters

Parameter	Description
consumer_group6	Name of the consumer group
group6_cpu	Percentage for group (deprecated)
consumer_group7	Name of the consumer group
group7_cpu	Percentage for group (deprecated)
consumer_group8	OTHER_GROUPS - all sessions that aren't mapped to a consumer group.
group8_cpu	Percentage for group (deprecated)
group1_percent	Percentage of resources allocated for this consumer group
group2_percent	Percentage of resources allocated for this consumer group
group3_percent	Percentage of resources allocated for this consumer group
group4_percent	Percentage of resources allocated for this consumer group
group5_percent	Percentage of resources allocated for this consumer group
group6_percent	Percentage of resources allocated for this consumer group
group7_percent	Percentage of resources allocated for this consumer group
group8_percent	Percentage of resources allocated to other groups

148.4.13 DELETE_CATEGORY Procedure

This procedure deletes an existing resource consumer group category.

Syntax

```
DBMS_RESOURCE_MANAGER.DELETE_CATEGORY (
   category        IN    VARCHAR2);
```

Parameters

Table 148-12 DELETE_CATEGORY Procedure Parameters

Parameter	Description
category	Name of consumer group category

148.4.14 DELETE_CDB_PLAN Procedure

This procedure deletes the consolidation resource plan.

Syntax

```
DBMS_RESOURCE_MANAGER.DELETE_CDB_PLAN (
   plan    IN    VARCHAR2(32)   DEFAULT NULL);
```

Parameters

Table 148-13 DELETE_CDB_PLAN Procedure Parameters

Parameter	Description
plan	Name of the consolidation plan

Usage Notes

This procedure can be run only from the CDB root (CDB$ROOT).

148.4.15 DELETE_CDB_PLAN_DIRECTIVE Procedure

This procedure deletes the plan directives of the consolidation resource plan. Once the plan directive is deleted, the pluggable database will get the default resource allocation.

Syntax

```
DBMS_RESOURCE_MANAGER.DELETE_CDB_PLAN_DIRECTIVE (
   plan                   IN    VARCHAR2(32)   DEFAULT NULL,
   pluggable_database     IN    VARCHAR2(32)   DEFAULT NULL);
```

Parameters

Table 148-14 DELETE_CDB_PLAN_DIRECTIVE Procedure Parameters

Parameter	Description
plan	Name of the consolidation plan
pluggable_database	Name of the pluggable database in which the plan directive is to be deleted

Usage Notes

This procedure can be run only from the CDB root (CDB$ROOT).

148.4.16 DELETE_CDB_PROFILE_DIRECTIVE Procedure

This procedure deletes the performance profile directive of the consolidation resource plan. Once the directive is deleted, the pluggable databases (PDBs) that use the performance profile use the default resource allocation.

For a PDB to use a performance profile, the PDB must have the DB_PERFORMANCE_PROFILE initialization parameter set to the performance profile name.

Syntax

```
DBMS_RESOURCE_MANAGER.DELETE_CDB_PROFILE_DIRECTIVE (
   plan          IN    VARCHAR2(32)   DEFAULT NULL,
   profile       IN    VARCHAR2(32)   DEFAULT NULL);
```

Parameters

Table 148-15 DELETE_CDB_PROFILE_DIRECTIVE Procedure Parameters

Parameter	Description
plan	Name of the consolidation plan
profile	Name of the performance profile directive to be deleted

Usage Notes

This procedure can be run only from the CDB root (CDB$ROOT).

148.4.17 DELETE_CONSUMER_GROUP Procedure

This procedure deletes entries which define resource consumer groups.

Syntax

```
DBMS_RESOURCE_MANAGER.DELETE_CONSUMER_GROUP (
   consumer_group IN VARCHAR2);
```

Parameters

Table 148-16 DELETE_CONSUMER_GROUP Procedure Parameters

Parameters	Description
consumer_group	Name of the consumer group to be deleted

148.4.18 DELETE_PLAN Procedure

This procedure deletes the specified plan as well as all the plan directives to which it refers.

Syntax

```
DBMS_RESOURCE_MANAGER.DELETE_PLAN (
   plan IN VARCHAR2);
```

Parameters

Table 148-17 DELETE_PLAN Procedure Parameters

Parameter	Description
plan	Name of the resource plan to delete

148.4.19 DELETE_PLAN_CASCADE Procedure

This procedure deletes the specified plan and all of its descendants (plan directives, subplans, consumer groups). Mandatory objects and directives are not deleted.

Syntax

```
DBMS_RESOURCE_MANAGER.DELETE_PLAN_CASCADE (
   plan IN VARCHAR2);
```

Parameters

Table 148-18 DELETE_PLAN_CASCADE Procedure Parameters

Parameters	Description
plan	Name of the plan

Usage Notes

If DELETE_PLAN_CASCADE encounters any error, then it rolls back the operation, and nothing is deleted.

148.4.20 DELETE_PLAN_DIRECTIVE Procedure

This procedure deletes resource plan directives.

Syntax

```
DBMS_RESOURCE_MANAGER.DELETE_PLAN_DIRECTIVE (
   plan              IN VARCHAR2,
   group_or_subplan  IN VARCHAR2);
```

Parameters

Table 148-19 DELETE_PLAN_DIRECTIVE Procedure Parameters

Parameter	Description
plan	Name of the resource plan
group_or_subplan	Name of the group or subplan

148.4.21 DEQUEUE_PARALLEL_STATEMENT Procedure

This procedure dequeues a parallel statement from the parallel statement queue.

If the PARALLEL_DEGREE_POLICY initialization parameter is set to AUTO or ADAPTIVE, then parallel statement queuing is enabled. If a parallel statement is in the parallel statement queue, then you can use this procedure to dequeue the parallel statement so that it runs immediately.

Syntax

```
DBMS_RESOURCE_MANAGER.DEQUEUE_PARALLEL_STATEMENT (
   session_id      IN  PLS_INTEGER,
   session_serial  IN  PLS_INTEGER,
   inst_id         IN  PLS_INTEGER  DEFAULT NULL,
   sql_id          IN  VARCHAR2 DEFAULT NULL);
```

Parameters

Table 148-20 DEQUEUE_PARALLEL_STATEMENT Procedure Parameters

Parameter	Description
session_id	The session id of the session running the parallel statement to be dequeued.
session_serial	The serial number of the session.
inst_id	Instance ID where the session is running. If NULL, then the current instance is used.
sql_id	The SQL ID of the session's statement to dequeue. If the session is running SQL with a different SQL ID, then the statement is not dequeued.

148.4.22 END_SQL_BLOCK Procedure

This procedure, to be used with parallel statement queuing, indicates the end of a block of SQL statements that should be treated as a group by resource manager.

Syntax

```
DBMS_RESOURCE_MANAGER.END_SQL_BLOCK;
```

Usage Notes

For more information, see "Parallel Statement Queuing" and "Managing Parallel Statement Queuing with Resource Manager" in *Oracle Database VLDB and Partitioning Guide*.

148.4.23 SET_CONSUMER_GROUP_MAPPING Procedure

This procedure adds, deletes, or modifies entries that map sessions to consumer groups, based on the session's login and runtime attributes.

Syntax

```
DBMS_RESOURCE_MANAGER.SET_CONSUMER_GROUP_MAPPING(
   attribute        IN VARCHAR2,
   value            IN VARCHAR2,
   consumer_group   IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 148-21 SET_CONSUMER_GROUP_MAPPING Procedure Parameters

Parameters	Description
attribute	Mapping attribute to add or modify. It can be one of the Constants listed.
value	Attribute value to match. This includes both absolute mapping and regular expressions.
consumer_group	Name of the mapped consumer group, or NULL to delete a mapping

Usage Notes

- If no mapping exists for the given attribute and value, a mapping to the given consumer group will be created. If a mapping already exists for the given attribute and value, the mapped consumer group will be updated to the one given. If the consumer_group argument is NULL, then any mapping from the given attribute and value will be deleted.
- The subprogram supports simple regex expressions for the value parameter. It implements the same semantics as the SQL 'LIKE' operator. Specifically, it uses '%' as amulticharacter wildcard and '_' as a single character wildcard. The '\' character can be used to escape the wildcards. Note that wildcards can only be used if the attribute is one of the following:
  - CLIENT_OS_USER
  - CLIENT_PROGRAM
  - CLIENT_MACHINE
  - MODULE_NAME
  - MODULE_NAME_ACTION
  - SERVICE_MODULE
  - SERVICE_MODULE_ACTION
- Consumer group mapping comparisons for DBMS_RESOURCE_MANAGER.CLIENT_PROGRAM are performed by stripping the @ sign and following characters from V$SESSION.PROGRAM before comparing it to the CLIENT_PROGRAM value supplied.

148.4.24 SET_CONSUMER_GROUP_MAPPING_PRI Procedure

Multiple attributes of a session can be used to map the session to a consumer group. This procedure prioritizes the attribute mappings.

Syntax

```
DBMS_RESOURCE_MANAGER.SET_CONSUMER_GROUP_MAPPING_PRI(
   explicit              IN NUMBER,
   oracle_user           IN NUMBER,
   service_name          IN NUMBER,
   client_os_user        IN NUMBER,
```

```
client_program         IN NUMBER,
client_machine         IN NUMBER,
module_name            IN NUMBER,
module_name_action     IN NUMBER,
service_module         IN NUMBER,
service_module_action  IN NUMBER,
client_id              IN NUMBER DEFAULT 11);
```

Parameters

Table 148-22 SET_CONSUMER_GROUP_MAPPING_PRI Procedure Parameters

Parameters	Description
explicit	Priority of the explicit mapping
oracle_user	Priority of the Oracle user name mapping
service_name	Priority of the client service name mapping
client_os_user	Priority of the client operating system user name mapping
client_program	Priority of the client program mapping
client_machine	Priority of the client machine mapping
module_name	Priority of the application module name mapping
module_name_action	Priority of the application module name and action mapping
service_module	Priority of the service name and application module name mapping
module_name_action	Priority of the service name, application module name, and application action mapping
client_id	Client identifier

Usage Notes

- This procedure requires that you include the pseudo-attribute `explicit` as an argument. It must be set to 1. It indicates that explicit consumer group switches have the highest priority. You explicitly switch consumer groups with these package procedures:
  - `DBMS_SESSION.SWITCH_CURRENT_CONSUMER_GROUP`
  - `DBMS_RESOURCE_MANAGER.SWITCH_CONSUMER_GROUP_FOR_SESS`
  - `DBMS_RESOURCE_MANAGER.SWITCH_CONSUMER_GROUP_FOR_USER`
- Each priority value must be a unique integer from 1 to 11. Together, they establish an ordering where 1 is the highest priority and 11 is the lowest.

148.4.25 SET_INITIAL_CONSUMER_GROUP Procedure

This deprecated procedure sets the initial resource consumer group for a user.

The initial consumer group of a user is the consumer group to which any session created by that user initially belongs.

> **Note:**
>
> This procedure is deprecated in Release 11gR1. While the procedure remains available in the package, Initial Consumer Group is set by the session-to-consumer group mapping rules.

Syntax

```
DBMS_RESOURCE_MANAGER.SET_INITIAL_CONSUMER_GROUP (
   user             IN   VARCHAR2,
   consumer_group   IN   VARCHAR2);
```

Parameters

Table 148-23 SET_INITIAL_CONSUMER_GROUP Procedure Parameters

Parameters	Description
`user`	Name of the user
`consumer_group`	User's initial consumer group

Usage Notes

- The `ADMINISTER_RESOURCE_MANAGER` or the `ALTER USER` system privilege are required to be able to execute this procedure. The user, or `PUBLIC`, must be directly granted switch privilege to a consumer group before it can be set to be the user's initial consumer group. Switch privilege for the initial consumer group cannot come from a role granted to that user.

  > **Note:**
  >
  > These semantics are similar to those for `ALTER USER DEFAULT ROLE`.

- If the initial consumer group for a user has never been set, then the user's initial consumer group is automatically the consumer group: `DEFAULT_CONSUMER_GROUP`.
- `DEFAULT_CONSUMER_GROUP` has switch privileges granted to `PUBLIC`; therefore, all users are automatically granted switch privilege for this consumer group. Upon deletion of a consumer group, all users having the deleted group as their initial consumer group now have `DEFAULT_CONSUMER_GROUP` as their initial consumer group. All currently active sessions belonging to a deleted consumer group are switched to `DEFAULT_CONSUMER_GROUP`.

148.4.26 SUBMIT_PENDING_AREA Procedure

This procedure submits pending changes for the resource manager. It clears the pending area after validating and committing the changes (if valid).

> **Note:**
>
> A call to SUBMIT_PENDING_AREA may fail even if VALIDATE_PENDING_AREA succeeds. This may happen if a plan being deleted is loaded by an instance after a call to VALIDATE_PENDING_AREA, but before a call to SUBMIT_PENDING_AREA.

Syntax

```
DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA;
```

148.4.27 SWITCH_CONSUMER_GROUP_FOR_SESS Procedure

This procedure changes the resource consumer group of a specific session. It also changes the consumer group of any parallel execution servers that are related to the top user session. This procedure is RAC instance specific. You need to connect to the PDB in same RAC instance where the session to be switched is running, and then run this procedure.

Syntax

```
DBMS_RESOURCE_MANAGER.SWITCH_CONSUMER_GROUP_FOR_SESS (
   session_id      IN NUMBER,
   session_serial  IN NUMBER,
   consumer_group  IN VARCHAR2);
```

Parameters

Table 148-24 SWITCH_CONSUMER_GROUP_FOR_SESS Procedure Parameters

Parameter	Description
session_id	SID column from the view V$SESSION
session_serial	SERIAL# column from view V$SESSION.
consumer_group	Name of the consumer group to which to switch

148.4.28 SWITCH_CONSUMER_GROUP_FOR_USER Procedure

This procedure changes the resource consumer group for all sessions with a given user ID. It also changes the consumer group of any parallel execution servers that are related to the top user session.

Syntax

```
DBMS_RESOURCE_MANAGER.SWITCH_CONSUMER_GROUP_FOR_USER (
   user            IN VARCHAR2,
   consumer_group  IN VARCHAR2);
```

Parameters

Table 148-25 SWITCH_CONSUMER_GROUP_FOR_USER Procedure Parameters

Parameter	Description
user	Name of the user
consumer_group	Name of the consumer group to which to switch

Usage Notes

- The SWITCH_CONSUMER_GROUP_FOR_SESS Procedure and the SWITCH_CONSUMER_GROUP_FOR_USER procedures let you raise or lower the allocation of CPU resources of certain sessions or users. This provides a functionality similar to the nice command on UNIX.
- These procedures cause the session to be moved into the newly specified consumer group immediately.

148.4.29 SWITCH_PLAN Procedure

This procedure sets the current resource manager plan.

Syntax

```
DBMS_RESOURCE_MANAGER.SWITCH_PLAN(
   plan_name                     IN   VARCHAR2,
   sid                           IN   VARCHAR2 DEFAULT '*',
   allow_scheduler_plan_switches IN   BOOLEAN DEFAULT TRUE);
```

Parameters

Table 148-26 SWITCH_PLAN Procedure Parameters

Parameter	Description
plan_name	Name of the plan to which to switch. Passing in an empty string ('') for the plan_name, disables the resource manager
sid	The sid parameter is relevant only in an Oracle Real Application Clusters environment. This parameter lets you change the plan for a particular instance. Specify the sid of the instance where you want to change the plan. Or specify '*' if you want Oracle to change the plan for all instances.
allow_scheduler_plan_switches	FALSE - disables automated plan switches by the job scheduler at window boundaries. To reenable automated plan switches, switch_plan must be called again by the administrator with allow_scheduler_plan_switches set to TRUE. By default automated plan switches by the job scheduler are enabled.

148.4.30 UPDATE_CATEGORY Procedure

This procedure updates an existing resource consumer group category.

Syntax

```
DBMS_RESOURCE_MANAGER.UPDATE_CATEGORY (
   category        IN    VARCHAR2,
   new_comment     IN    VARCHAR2  DEFAULT NULL);
```

Parameters

Table 148-27 UPDATE_CATEGORY Procedure Parameters

Parameter	Description
category	Name of consumer group category
new_comment	User comment

Usage Notes

To clear (reset to the directive's default value), use the value `-1`.

148.4.31 UPDATE_CDB_AUTOTASK_DIRECTIVE Procedure

This procedure updates the plan directives with regard to automated maintenance tasks in the CDB root (`CDB$ROOT`).

By default, all maintenance tasks occur directly in the PDBs themselves.

Syntax

```
DBMS_RESOURCE_MANAGER.UPDATE_CDB_AUTOTASK_DIRECTIVE (
   plan                         IN    VARCHAR2,
   new_comment                  IN    VARCHAR2       DEFAULT NULL,
   new_shares                   IN    NUMBER         DEFAULT NULL,
   new_utilization_limit        IN    NUMBER         DEFAULT NULL,
   new_parallel_server_limit    IN    NUMBER         DEFAULT NULL,
   new_memory_limit             IN    NUMBER         DEFAULT NULL,
   new_memory_min               IN    NUMBER         DEFAULT NULL);
```

Parameters

Table 148-28 UPDATE_CDB_AUTOTASK_DIRECTIVE Procedure Parameters

Parameter	Description
plan	Name of the consolidation plan
new_comment	New user comment
new_shares	Specifies the new share of resource allocation for CDB root's automated maintenance tasks
new_utilization_limit	Specifies the new maximum percentage of CPU that automated maintenance tasks in the CDB root can utilize

Table 148-28 (Cont.) UPDATE_CDB_AUTOTASK_DIRECTIVE Procedure Parameters

Parameter	Description
new_parallel_server_limit	Specifies the new maximum percentage of parallel_servers_target parallel servers that automated maintenance tasks in the CDB root are allowed to use
new_memory_limit	This parameter is only applicable to Oracle Exadata storage for configuring the Database Smart Flash Cache and PMEM Cache.
new_memory_min	This parameter is only applicable to Oracle Exadata storage for configuring the Database Smart Flash Cache and PMEM Cache.

Usage Notes

- By default for automated maintenance tasks, the values are
  - shares: -1
  - utilization_limit: 90
  - parallel_server_limit: 100
- The shares = -1 means that the automated maintenance tasks get an allocation of 20% of the system. If the user specifies the shares, it behaves the same properties as the other CDB plan directive functions. If the user does not change the shares or later changes it back to -1, autotask will get 20% of the system.
- This procedure can be run only from the CDB root.
- To clear (reset to the directive's default value), use the value -1.

148.4.32 UPDATE_CDB_DEFAULT_DIRECTIVE Procedure

This procedure updates the plan directives of the consolidation resource plan.

Syntax

```
DBMS_RESOURCE_MANAGER.UPDATE_CDB_DEFAULT_DIRECTIVE (
   plan                        IN    VARCHAR2    DEFAULT NULL,
   new_comment                 IN    VARCHAR2    DEFAULT NULL,
   new_shares                  IN    NUMBER      DEFAULT NULL,
   new_utilization_limit       IN    NUMBER      DEFAULT NULL,
   new_parallel_server_limit   IN    NUMBER      DEFAULT NULL,
   new_memory_limit            IN    NUMBER      DEFAULT NULL,
   new_memory_min              IN    NUMBER      DEFAULT NULL);
```

Parameters

Table 148-29 UPDATE_CDB_DEFAULT_DIRECTIVE Procedure Parameters

Parameter	Description
plan	Name of the consolidation plan
new_commnent	New user comment

Table 148-29 (Cont.) UPDATE_CDB_DEFAULT_DIRECTIVE Procedure Parameters

Parameter	Description
new_shares	Specifies the share of resource allocation for the pluggable database. CPU Resource Manager and Exadata I/O Resource Manager are enabled by specifying shares for each PDB. The new_shares parameter is also used for Parallel Statement Queuing.
new_utilization_limit	Specifies the maximum percentage of CPU that the pluggable database can utilize.
new_parallel_server_limit	Specifies the maximum percentage of parallel_servers_target parallel servers that the pluggable database can use.
new_memory_limit	This parameter is only applicable to Oracle Exadata storage for configuring the Database Smart Flash Cache and PMEM Cache.
new_memory_min	This parameter is only applicable to Oracle Exadata storage for configuring the Database Smart Flash Cache and PMEM Cache.

Usage Notes

- By default, the default values are
  - new_shares: 1
  - utilization_limit: 100
  - parallel_server_limit: 100
- Note that the default values are NULL. This has the same meaning as in UPDATE_CDB_PLAN_DIRECTIVE Procedure. If the user does not specify a value, the value will not be modified.
- This procedure can be run only from the CDB root (CDB$ROOT).
- To clear (reset to the directive's default value), use the value -1.

148.4.33 UPDATE_CDB_PLAN Procedure

This procedure updates the consolidation resource plan.

Syntax

```
DBMS_RESOURCE_MANAGER.UPDATE_CDB_PLAN (
   plan                        IN    VARCHAR2(32),
   new_comment                 IN    VARCHAR2(2000)   DEFAULT NULL);
```

Parameters

Table 148-30 UPDATE_CDB_PLAN Procedure Parameters

Parameter	Description
plan	Name of the consolidation plan

Table 148-30 (Cont.) UPDATE_CDB_PLAN Procedure Parameters

Parameter	Description
new_comment	User comment

Usage Notes

- This procedure can be run only from the CDB root (CDB$ROOT).
- To clear (reset to the directive's default value), use the value -1.

148.4.34 UPDATE_CDB_PLAN_DIRECTIVE Procedure

Updates the plan directives for a consolidation resource plan. Plan directives specify the resource allocation policy for pluggable databases (PDBs).

Syntax

```
DBMS_RESOURCE_MANAGER.UPDATE_CDB_PLAN_DIRECTIVE (
   plan                        IN    VARCHAR2 (30),
   pluggable_database          IN    VARCHAR2 (30)
   new_comment                 IN    VARCHAR2 (200)  DEFAULT NULL,
   new_shares                  IN    NUMBER          DEFAULT NULL,
   new_utilization_limit       IN    NUMBER          DEFAULT NULL,
   new_parallel_server_limit   IN    NUMBER          DEFAULT NULL,
   new_memory_limit            IN    NUMBER          DEFAULT NULL,
   new_memory_min              IN    NUMBER          DEFAULT NULL);
```

Parameters

Table 148-31 UPDATE_CDB_PLAN_DIRECTIVE Procedure Parameters

Parameter	Description
plan	Name of the consolidation plan
pluggable_database	Name of the pluggable database
new_comment	New user comment
new_shares	The share of resource allocation for the pluggable database CPU Resource Manager is enabled by specifying shares for each PDB. The shares parameter is also used for Parallel Statement Queuing. If no share is specified, the default is obtained from the default directive, specified through the UPDATE_CDB_DEFAULT_DIRECTIVE Procedure.
new_utilization_limit	The new maximum percentage of CPU that the pluggable database can utilize
new_parallel_server_limit	The new maximum percentage of parallel_servers_target parallel servers that the pluggable database can use
new_memory_limit	This parameter is only applicable to Oracle Exadata storage for configuring the Database Smart Flash Cache and PMEM Cache.

Table 148-31 (Cont.) UPDATE_CDB_PLAN_DIRECTIVE Procedure Parameters

Parameter	Description
new_memory_ min	This parameter is only applicable to Oracle Exadata storage for configuring the Database Smart Flash Cache and PMEM Cache.

Usage Notes

- The default value for the new_* parameters is NULL which indicates that the existing value is left unchanged. If the user does not specify one of the arguments when calling this function, the value is not modified.
- This procedure can be run only from the CDB root (CDB$ROOT).
- To clear (reset to the directive's default value), use the value -1.

148.4.35 UPDATE_CDB_PROFILE_DIRECTIVE Procedure

This procedure updates the performance profile directives of the consolidation resource plan. The directives specify the resource allocation policy for pluggable databases (PDBs) that use the performance profile.

For a PDB to use a performance profile, the PDB must have the DB_PERFORMANCE_PROFILE initialization parameter set to the performance profile name.

Syntax

```
DBMS_RESOURCE_MANAGER.UPDATE_CDB_PROFILE_DIRECTIVE (
   plan                        IN    VARCHAR2,
   profile                     IN    VARCHAR2,
   new_comment                 IN    VARCHAR2 (2000) DEFAULT '',
   new_shares                  IN    NUMBER          DEFAULT NULL,
   new_utilization_limit       IN    NUMBER          DEFAULT NULL,
   new_parallel_server_limit   IN    NUMBER          DEFAULT NULL,
   new_memory_limit            IN    NUMBER          DEFAULT 100,
   new_memory_min              IN    NUMBER          DEFAULT 0);
```

Parameters

Table 148-32 UPDATE_CDB_PROFILE_DIRECTIVE Procedure Parameters

Parameter	Description
plan	Name of the consolidation plan
profile	Name of the performance profile
new_comment	New user comment
new_shares	The share of resource allocation for the PDBs that use the performance profile
new_utilization_limit	The new maximum percentage of CPU that PDBs that use the performance profile can use
new_parallel_server_limit	The new maximum percentage of parallel_servers_target parallel servers that PDBs that use the performance profile can use

Table 148-32 (Cont.) UPDATE_CDB_PROFILE_DIRECTIVE Procedure Parameters

Parameter	Description
new_memory_limit	This parameter is only applicable to Oracle Exadata storage for configuring the Database Smart Flash Cache and PMEM Cache.
new_memory_ min	This parameter is only applicable to Oracle Exadata storage for configuring the Database Smart Flash Cache and PMEM Cache.

Usage Notes

- This procedure can be run only from the CDB root (CDB$ROOT).
- To clear (reset to the directive's default value), use the value -1.

148.4.36 UPDATE_CONSUMER_GROUP Procedure

This procedure updates entries which define resource consumer groups.

Syntax

```
DBMS_RESOURCE_MANAGER.UPDATE_CONSUMER_GROUP (
   consumer_group  IN VARCHAR2,
   new_comment     IN VARCHAR2 DEFAULT NULL,
   new_cpu_mth     IN VARCHAR2 DEFAULT NULL,
   new_mgmt_mth    IN VARCHAR2 DEFAULT NULL,
   new_category    IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 148-33 UPDATE_CONSUMER_GROUP Procedure Parameter

Parameter	Description
consumer_group	Name of consumer group
new_comment	New user comment
new_cpu_mth	Name of new method for CPU resource allocation (deprecated)
new_mgmt_mth	Name of new method for CPU resource allocation
new_category	New consumer group category

Usage Notes

- If the parameters to the UPDATE_CONSUMER_GROUP procedure are not specified, then they remain unchanged in the data dictionary.
- To clear (reset to the directive's default value), use the value -1.

148.4.37 UPDATE_PLAN Procedure

This procedure updates entries which define resource plans.

Syntax

```
DBMS_RESOURCE_MANAGER.UPDATE_PLAN (
   plan                              IN VARCHAR2,
   new_comment                       IN VARCHAR2 DEFAULT NULL,
   new_cpu_mth                       IN VARCHAR2 DEFAULT NULL, -- deprecated
   new_active_sess_pool_mth          IN VARCHAR2 DEFAULT NULL,
   new_parallel_degree_limit_mth     IN VARCHAR2 DEFAULT NULL,
   new_queueing_mth                  IN VARCHAR2 DEFAULT NULL,
   new_mgmt_mth                      IN VARCHAR2 DEFAULT NULL,
   new_sub_plan                      IN BOOLEAN DEFAULT FALSE,
   new_max_iops                      IN NUMBER DEFAULT NULL,
   new_max_mbps                      IN NUMBER DEFAULT NULL);
```

Parameters

Table 148-34 UPDATE_PLAN Procedure Parameters

Parameter	Description
`plan`	Name of resource plan
`new_comment`	New user comment
`new_cpu_mth`	Name of new allocation method for CPU resources (deprecated)
`new_active_sess_pool_mth`	Name of new method for maximum active sessions
`new_parallel_degree_limit_mth`	Name of new method for degree of parallelism
`new_queueing_mth`	Specifies type of queuing policy to use with active session pool feature
`new_mgmt_mth`	Resource allocation method for specifying how much resources (for example, CPU or I/O) each consumer group or sub-plan gets • `EMPHASIS` - for multilevel plans that use percentages to specify how I/O resources are distributed among consumer groups. • `RATIO` - for single-level plans that use ratios to specify how I/O resources are distributed.
`new_sub_plan`	New setting for whether the plan is only intended for use as a sub-plan
`new_max_iops`	Nonoperative
`new_max_mbps`	Nonoperative

Usage Notes

- If the parameters to UPDATE_PLAN Procedure are not specified, then they remain unchanged in the data dictionary.
- If you want to use any default resource allocation method, then you do not need to specify it when creating or updating a plan.
- To clear (reset to the directive's default value), use the value `-1`.

148.4.38 UPDATE_PLAN_DIRECTIVE Procedure

This procedure updates resource plan directives.

> **Note:**
>
> The parameters `new_max_utilization_limit` and `new_parallel_target_percentage` are deprecated with Oracle Database 11g Release 1 (12.1.0.1), and are replaced by `new_utilization_limit` and `new_parallel_server_limit`.

Syntax

```
DBMS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE (
   plan                          IN VARCHAR2,
   group_or_subplan              IN VARCHAR2,
   new_comment                   IN VARCHAR2 DEFAULT NULL,
   new_cpu_p1                    IN NUMBER   DEFAULT NULL, -- deprecated
   new_cpu_p2                    IN NUMBER   DEFAULT NULL, -- deprecated
   new_cpu_p3                    IN NUMBER   DEFAULT NULL, -- deprecated
   new_cpu_p4                    IN NUMBER   DEFAULT NULL, -- deprecated
   new_cpu_p5                    IN NUMBER   DEFAULT NULL, -- deprecated
   new_cpu_p6                    IN NUMBER   DEFAULT NULL, -- deprecated
   new_cpu_p7                    IN NUMBER   DEFAULT NULL, -- deprecated
   new_cpu_p8                    IN NUMBER   DEFAULT NULL, -- deprecated
   new_active_sess_pool_p1       IN NUMBER   DEFAULT NULL,
   new_queueing_p1               IN NUMBER   DEFAULT NULL,
   new_parallel_degree_limit_p1  IN NUMBER   DEFAULT NULL,
   new_switch_group              IN VARCHAR2 DEFAULT NULL,
   new_switch_time               IN NUMBER   DEFAULT NULL,
   new_switch_estimate           IN BOOLEAN  DEFAULT FALSE,
   new_max_est_exec_time         IN NUMBER   DEFAULT NULL,
   new_undo_pool                 IN NUMBER   DEFAULT NULL,
   new_max_idle_time             IN NUMBER   DEFAULT NULL,
   new_max_idle_blocker_time     IN NUMBER   DEFAULT NULL,
   switch_time_in_call           IN NUMBER   DEFAULT NULL, -- deprecated
   new_mgmt_p1                   IN NUMBER   DEFAULT NULL,
   new_mgmt_p2                   IN NUMBER   DEFAULT NULL,
   new_mgmt_p3                   IN NUMBER   DEFAULT NULL,
   new_mgmt_p4                   IN NUMBER   DEFAULT NULL,
   new_mgmt_p5                   IN NUMBER   DEFAULT NULL,
   new_mgmt_p6                   IN NUMBER   DEFAULT NULL,
   new_mgmt_p7                   IN NUMBER   DEFAULT NULL,
   new_mgmt_p8                   IN NUMBER   DEFAULT NULL,
   new_switch_io_megabytes       IN NUMBER   DEFAULT NULL,
   new_switch_io_reqs            IN NUMBER   DEFAULT NULL,
   new_switch_for_call           IN BOOLEAN  DEFAULT NULL,
   new_max_utilization_limit     IN NUMBER   DEFAULT NULL,
   new_parallel_target_percentage IN NUMBER  DEFAULT NULL,
   new_parallel_queue_timeout    IN NUMBER   DEFAULT NULL,
   new_parallel_server_limit     IN NUMBER   DEFAULT NULL,
   new_utilization_limit         IN NUMBER   DEFAULT NULL,
   new_switch_io_logical         IN NUMBER   DEFAULT NULL,
   new_switch_elapsed_time       IN NUMBER   DEFAULT NULL,
   new_shares                    IN NUMBER   DEFAULT NULL,
```

```
  new_parallel_stmt_critical       IN VARCHAR2 DEFAULT NULL,
  new_session_pga_limit            IN NUMBER   DEFAULT NULL,
  new_pq_timeout_action            IN NUMBER   DEFAULT NULL);
```

Parameters

Table 148-35 UPDATE_PLAN_DIRECTIVE Procedure Parameters

Parameter	Description
plan	Name of the resource plan
group_or_subplan	Name of the consumer group or subplan
new_comment	Comment for the plan directive
new_cpu_p1	Deprecated - use new_mgmt_p1 instead
new_cpu_p2	Deprecated - use new_mgmt_p2 instead
new_cpu_p3	Deprecated - use new_mgmt_p3 instead
new_cpu_p4	Deprecated- use new_mgmt_p4 instead
new_cpu_p5	Deprecated - use new_mgmt_p5 instead
new_cpu_p6	Deprecated- use new_mgmt_p6 instead
new_cpu_p7	Deprecated- use new_mgmt_p7 instead
new_cpu_p8	Deprecated- use new_mgmt_p8 instead
new_active_sess_pool_p1	Specifies maximum number of concurrently active sessions for a consumer group. Default is NULL, which means unlimited.
new_queueing_p1	Specified time (in seconds) after which a job in the inactive session queue (waiting for execution) will time out. Default is NULL, which means unlimited.
new_parallel_degree_limit_p1	Specifies a limit on the degree of parallelism for any operation. Default is NULL, which means unlimited.
new_switch_group	Specifies consumer group to which this session is switched if other switch criteria are met. Default is NULL. If the group name is 'CANCEL_SQL', the current call will be canceled when other switch criteria are met. If the group name is 'KILL_SESSION', the session will be killed when other switch criteria are met.
new_switch_time	Specifies time (in CPU seconds) that a session can execute before an action is taken. Default is NULL, which means unlimited.
new_switch_estimate	If TRUE, tells Oracle to use its execution time estimate to automatically switch the consumer group of an operation before beginning its execution. Default is FALSE.
new_max_est_exec_time	Specifies the maximum execution time (in CPU seconds) allowed for a session. If the optimizer estimates that an operation will take longer than MAX_EST_EXEC_TIME, the operation is not started and ORA-07455 is issued. If the optimizer does not provide an estimate, this directive has no effect. Default is NULL, which means unlimited.
new_undo_pool	Limits the size in kilobytes of the undo records corresponding to uncommitted transactions by this consumer group
new_max_idle_time	Indicates the maximum session idle time. Default is NULL, which means unlimited.
new_max_idle_blocker_time	Maximum amount of time in seconds that a session can be idle while blocking another session's acquisition of a resource

Table 148-35 (Cont.) UPDATE_PLAN_DIRECTIVE Procedure Parameters

Parameter	Description
new_switch_time_in_call	Deprecated. If this parameter is specified, new_switch_time will be effectively set to new_switch_time_in_call and new_switch_for_call will be effectively set to TRUE.
new_mgmt_p1	Resource allocation value for level 1 (replaces new_cpu_p1): • EMPHASIS - specifies the resource percentage at the first level • RATIO - specifies the weight of resource usage
new_mgmt_p2	Resource allocation value for level 2 (replaces new_cpu_p2) • EMPHASIS - specifies the resource percentage at the second level • RATIO - non-applicable
new_mgmt_p3	Resource allocation value for level 3 (replaces new_cpu_p3) • EMPHASIS - specifies the resource percentage at the third level • RATIO - non-applicable
new_mgmt_p4	Resource allocation value for level 4 (replaces new_cpu_p4) • EMPHASIS - specifies the resource percentage at the fourth level • RATIO - non-applicable
new_mgmt_p5	Resource allocation value for level 5 (replaces new_cpu_p5) • EMPHASIS - specifies the resource percentage at the fifth level • RATIO - non-applicable
new_mgmt_p6	Resource allocation value for level 6 (replaces new_cpu_p6) • EMPHASIS - specifies the resource percentage at the sixth level • RATIO - non-applicable
new_mgmt_p7	Resource allocation value for level 7 (replaces new_cpu_p7) • EMPHASIS - specifies the resource percentage at the seventh level • RATIO - non-applicable
new_mgmt_p8	Resource allocation value for level 8 (replaces new_cpu_p8) • EMPHASIS - specifies the resource percentage at the eighth level • RATIO - non-applicable
new_switch_io_megabytes	Specifies the amount of I/O (in MB) that a session can issue before an action is taken. Default is NULL, which means unlimited.
new_switch_io_reqs	Specifies the number of I/O requests that a session can issue before an action is taken. Default is NULL, which means unlimited.
new_switch_for_call	Specifies that if an action is taken because of the new_switch_time, new_switch_io_megabytes, or new_switch_io_reqs parameters, the consumer group is restored to its original consumer group at the end of the top call. Default is FALSE, which means that the original consumer group is not restored at the end of the top call.
new_max_utilization_limit	Deprecated - use new_utilization_limit instead
new_parallel_target_percentage	Deprecated - use new_parallel_server_limit instead
new_parallel_server_limit	Parallel server limit. Setting this overwrites the limit for parallel server set by utilization_limit.

Table 148-35 (Cont.) UPDATE_PLAN_DIRECTIVE Procedure Parameters

Parameter	Description
new_utilization_limit	Resource limit. For CPU, this limits the CPU utilization for the consumer group. For parallel servers, this limits the parallel servers used as a percentage of parallel_servers_target.
new_switch_elapsed_time	Elapsed time that will trigger the action specified by switch_group. As with other switch directives, if new_switch_for_call is TRUE, the elapsed time is accumulated from the start of a call. Otherwise, the elapsed time is accumulated for the length of the session.
new_shares	Specifies the share of resource allocation for the pluggable database. CPU Resource Manager and Exadata I/O Resource Manager are enabled by specifying shares for each PDB. The shares parameter is also used for Parallel Statement Queuing. If CPU Resource Manager and Exadata I/O Resource Manager are enabled, then the default value is 1.
new_parallel_stmt_critical	If set to BYPASS_QUEUE, parallel statements from this consumer group are not queued. If set to QUEUE, all the parallel statements, irrespective of the parallel_degree_policy parameter value, from the consumer group get queued. Default is FALSE, which means that certain parallel statements are eligible for queuing depending upon the parallel_degree_policy parameter value.
new_session_pga_limit	Maximum amount of PGA in MB that sessions in this consumer group can allocate before being terminated. NULL (default) indicates no change.
new_parallel_queue_timeout	Specifies the time (in seconds) that a parallel statement may remain in its Consumer Group's parallel statement queue before it is removed. The default action of this parameter is ERROR. This action can be altered using the new_pq_timeout_action parameter.
new_pq_timeout_action	Specifies the action to be taken when a parallel statement is removed from the queue due to new_parallel_queue_timeout. The values are: • CANCEL — The SQL statement is terminated with error ORA-7454 • RUN — The SQL statement runs immediately, and might get downgraded if parallel servers are unavailable

Usage Notes

- If the parameters for UPDATE_PLAN_DIRECTIVE are left unspecified, then they remain unchanged in the data dictionary.
- For new_max_idle_time and new_max_idle_blocker_time, PMON will check these limits once a minute. If it finds a session that has exceeded one of the limits, it will forcibly kill the session and clean up all its state.
- The parameter new_switch_time_in_call is mostly useful for three-tier applications where the mid-tier server is implementing session pooling. By turning on new_switch_time_in_call, the resource usage of one client will not affect the consumer group of a future client that happens to be executed on the same session.
- To clear (reset to the directive's default value), use the value -1.

148.4.39 VALIDATE_PENDING_AREA Procedure

This procedure validates pending changes for the resource manager.

Syntax

```
DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA;
```

149
DBMS_RESOURCE_MANAGER_PRIVS

The DBMS_RESOURCE_MANAGER_PRIVS package maintains privileges associated with the Resource Manager.

This chapter contains the following topics:

- Summary of DBMS_RESOURCE_MANAGER_PRIVS Subprograms

> **See Also:**
>
> For more information on using the Database Resource Manager, see*Oracle Database Administrator's Guide*

149.1 Summary of DBMS_RESOURCE_MANAGER_PRIVS Subprograms

This table lists the DBMS_RESOURCE_MANAGER_PRIVS subprograms and briefly describes them.

Table 149-1 DBMS_RESOURCE_MANAGER_PRIVS Package Subprograms

Subprogram	Description
GRANT_SWITCH_CONSUMER_GROUP Procedure	Grants the privilege to switch to resource consumer groups
GRANT_SYSTEM_PRIVILEGE Procedure	Performs a grant of a system privilege
REVOKE_SWITCH_CONSUMER_GROUP Procedure	Revokes the privilege to switch to resource consumer groups.
REVOKE_SYSTEM_PRIVILEGE Procedure	Performs a revoke of a system privilege

149.1.1 GRANT_SWITCH_CONSUMER_GROUP Procedure

This procedure grants the privilege to switch to a resource consumer group.

Syntax

```
DBMS_RESOURCE_MANAGER_PRIVS.GRANT_SWITCH_CONSUMER_GROUP (
   grantee_name   IN VARCHAR2,
   consumer_group IN VARCHAR2,
   grant_option   IN BOOLEAN);
```

Parameters

Table 149-2 GRANT_SWITCH_CONSUMER_GROUP Procedure Parameters

Parameter	Description
grantee_name	Name of the user or role to whom privilege is to be granted.
consumer_group	Name of consumer group.
grant_option	TRUE if grantee should be allowed to grant access, FALSE otherwise.

Usage Notes

If you grant permission to switch to a particular consumer group to a user, then that user can immediately switch their current consumer group to the new consumer group.

If you grant permission to switch to a particular consumer group to a role, then any users who have been granted that role and have enabled that role can immediately switch their current consumer group to the new consumer group.

If you grant permission to switch to a particular consumer group to PUBLIC, then any user can switch to that consumer group.

If the grant_option parameter is TRUE, then users granted switch privilege for the consumer group may also grant switch privileges for that consumer group to others.

In order to set the initial consumer group of a user, you must grant the switch privilege for that group to the user.

> **See Also:**
>
> DBMS_RESOURCE_MANAGER

Examples

```
BEGIN
DBMS_RESOURCE_MANAGER_PRIVS.GRANT_SWITCH_CONSUMER_GROUP (
 'scott', 'mail_maintenance_group', true);
DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
DBMS_RESOURCE_MANAGER.set_consumer_group_mapping(
  dbms_resource_manager.oracle_user, 'scott','mail_maintenance_group');
DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
END;
/
```

149.1.2 GRANT_SYSTEM_PRIVILEGE Procedure

This procedure performs a grant of a system privilege to a user or role.

Syntax

```
DBMS_RESOURCE_MANAGER_PRIVS.GRANT_SYSTEM_PRIVILEGE (
   grantee_name    IN VARCHAR2,
```

```
   privilege_name  IN VARCHAR2 DEFAULT 'ADMINISTER_RESOURCE_MANAGER',
   admin_option    IN BOOLEAN);
```

Parameters

Table 149-3 GRANT_SYSTEM_PRIVILEGE Procedure Parameters

Parameter	Description
grantee_name	Name of the user or role to whom privilege is to be granted.
privilege_name	Name of the privilege to be granted.
admin_option	TRUE if the grant is with admin_option, FALSE otherwise.

Usage Notes

Currently, Oracle provides only one system privilege for the Resource Manager: ADMINISTER_RESOURCE_MANAGER. Database administrators have this system privilege with the ADMIN option. The grantee and the revokee can either be a user or a role. Users that have been granted the system privilege with the ADMIN option can also grant this privilege to others.

Examples

The following call grants this privilege to a user called scott without the ADMIN option:

```
BEGIN
DBMS_RESOURCE_MANAGER_PRIVS.GRANT_SYSTEM_PRIVILEGE (
 grantee_name => 'scott',
 privilege_name => 'ADMINISTER_RESOURCE_MANAGER',
 admin_option => FALSE);
END;
/
```

149.1.3 REVOKE_SWITCH_CONSUMER_GROUP Procedure

This procedure revokes the privilege to switch to a resource consumer group.

Syntax

```
DBMS_RESOURCE_MANAGER_PRIVS.REVOKE_SWITCH_CONSUMER_GROUP (
   revokee_name   IN VARCHAR2,
   consumer_group IN VARCHAR2);
```

Parameters

Table 149-4 REVOKE_SWITCH_CONSUMER_GROUP Procedure Parameter

Parameter	Description
revokee_name	Name of user/role from which to revoke access.
consumer_group	Name of consumer group.

Usage Notes

If you revoke a user's switch privilege for a particular consumer group, then any subsequent attempts by that user to switch to that consumer group will fail.

If you revoke the initial consumer group from a user, then that user will automatically be part of the DEFAULT_CONSUMER_GROUP consumer group when logging in.

If you revoke the switch privilege for a consumer group from a role, then any users who only had switch privilege for the consumer group through that role will not be able to switch to that consumer group.

If you revoke the switch privilege for a consumer group from PUBLIC, then any users who could previously only use the consumer group through PUBLIC will not be able to switch to that consumer group.

Examples

The following example revokes the privileges to switch to mail_maintenance_group from Scott:

```
BEGIN
DBMS_RESOURCE_MANAGER_PRIVS.REVOKE_SWITCH_CONSUMER_GROUP (
 'scott', 'mail_maintenance_group');
END;
/
```

149.1.4 REVOKE_SYSTEM_PRIVILEGE Procedure

This procedure performs a revoke of a system privilege from a user or role.

Syntax

```
DBMS_RESOURCE_MANAGER_PRIVS.REVOKE_SYSTEM_PRIVILEGE (
   revokee_name   IN VARCHAR2,
   privilege_name IN VARCHAR2 DEFAULT 'ADMINISTER_RESOURCE_MANAGER');
```

Parameters

Table 149-5 REVOKE_SYSTEM_PRIVILEGE Procedure Parameters

Parameter	Description
revokee_name	Name of the user or role from whom privilege is to be revoked.
privilege_name	Name of the privilege to be revoked.

Examples

The following call revokes the ADMINISTER_RESOURCE_MANAGER from user scott:

```
BEGIN
DBMS_RESOURCE_MANAGER_PRIVS.REVOKE_SYSTEM_PRIVILEGE ('scott');
END;
/
```

150
DBMS_RESULT_CACHE

The DBMS_RESULT_CACHE package provides an interface to allow the DBA to administer that part of the shared pool that is used by the SQL result cache and the PL/SQL function result cache.

Both these caches use the same infrastructure. Therefore, for example, DBMS_RESULT_CACHE.BYPASS determines whether both caches are bypassed or both caches are used, and DBMS_RESULT_CACHE.FLUSH flushes both all the cached results for SQL queries and all the cached results for PL/SQL functions.

This chapter contains the following topics:

- Security Model
- Constants
- Summary of DBMS_RESULT_CACHE Subprograms

> **See Also:**
>
> - *Oracle Database Performance Tuning Guide*, for more information about "Result Cache Concepts"
> - *Oracle Database PL/SQL Language Reference*, for more information about PL/SQL function Result Cache "Using the Cross-Session PL/SQL Function Result Cache"
> - *Database PL/SQL Language Reference*, for more information about Result Cache Management.

150.1 DBMS_RESULT_CACHE Security Model

Only database administrators should be granted the EXECUTE privilege for this package.

150.2 DBMS_RESULT_CACHE Constants

The DBMS_RESULT_CACHE package defines several constants for specifying parameter values.

The following table describes these constants.

Table 150-1 DBMS_RESULT_CACHE Constants

Constant	Definition	Description
STATUS_BYPS	CONSTANT VARCHAR2(10) := 'BYPASS';	Cache has been made temporarilyunavailable.

Table 150-1 (Cont.) DBMS_RESULT_CACHE Constants

Constant	Definition	Description
STATUS_CORR	CONSTANT VARCHAR2(10) := 'CORRUPT';	The result cache is in an unusable state.
STATUS_DISA	CONSTANT VARCHAR2(10) := 'DISABLED';	Cache is not available.
STATUS_ENAB	CONSTANT VARCHAR2(10) := 'ENABLED';	Cache is available.
STATUS_SYNC	CONSTANT VARCHAR2(10) := 'SYNC';	Cache is available, but synchronizing with Oracle RAC nodes.

150.3 Summary of DBMS_RESULT_CACHE Subprograms

This table lists the DBMS_RESULT_CACHE subprograms and briefly describes them.

Table 150-2 DBMS_RESULT_CACHE Package Subprograms

Subprogram	Description
BLACK_LIST Function	Returns all the blocklisted cache ids of a local instance.
BLACK_LIST_ADD Procedure	Adds a cache_id to the blocklist.
BLACK_LIST_CLEAR Procedure	Removes all cache_ids from the blocklist.
BLACK_LIST_REMOVE Procedure	Removes the cache_id from the blocklist.
BYPASS Procedure	Sets the bypass mode for the result cache.
FLUSH Function & Procedure	Attempts to remove all the objects from the result cache, and depending on the arguments retains or releases the memory and retains or clears the statistics.
INVALIDATE Functions & Procedures	Invalidates all the result-set objects that are dependent upon the specified dependency object.
INVALIDATE_OBJECT Functions & Procedures	Invalidates the specified result-set object(s)
MEMORY_REPORT Procedure	Produces the memory usage report for the result cache.
OBJECT_BLACK_LIST Function	Returns all the object numbers currently in the blocklist
OBJECT_BLACK_LIST_ADD Procedure	Adds objects to the object blocklist
OBJECT_BLACK_LIST_CLEAR Procedure	Clears the entire blocklist
OBJECT_BLACK_LIST_REMOVE Procedure	Removes objects from the object blocklist.
STATUS Function	Checks the status of the result cache.

150.3.1 BLACK_LIST Function

This table function returns all the blocklisted cache ids of a local instance.

Syntax

```
DBMS_RESULT_CACHE.BLACK_LIST
   RETURN BL_TABT;
```

150.3.2 BLACK_LIST_ADD Procedure

This procedure adds a cache_id to the blocklist.

Syntax

```
DBMS_RESULT_CACHE.BLACK_LIST_ADD (
   cache_id   IN  VARCHAR2,
   global     IN  BOOLEAN DEFAULT FALSE);
```

Parameters

Table 150-3 BLACK_LIST_ADD Procedure Parameters

Parameter	Description
cache_id	The cache_id is added to the blocklist.
global	TRUE — applies to all caches in a RAC cluster. FALSE (default) — applies only to the local instance cache.

150.3.3 BLACK_LIST_CLEAR Procedure

This procedure removes all cache_ids from the blocklist.

Syntax

```
DBMS_RESULT_CACHE.BLACK_LIST_CLEAR (
   global   IN  BOOLEAN DEFAULT FALSE);
```

Parameters

Table 150-4 BLACK_LIST_CLEAR Procedure Parameters

Parameter	Description
global	TRUE — applies to all caches in a RAC cluster. FALSE (default) — applies only to the local instance cache.

150.3.4 BLACK_LIST_REMOVE Procedure

This procedures removes the cache_id from the blocklist.

Syntax

```
DBMS_RESULT_CACHE.BLACK_LIST_REMOVE (
   cache_id   IN  VARCHAR2,
   global     IN  BOOLEAN DEFAULT FALSE);
```

Parameters

Table 150-5 BLACK_LIST_REMOVE Procedure Parameters

Parameter	Description
cache_id	The cache_id is removed from the blocklist.
global	TRUE — applies to all caches in a RAC cluster. FALSE (default) — applies only to the local instance cache.

150.3.5 BYPASS Procedure

This procedure sets the bypass mode for the Result Cache.

It sets one of the following bypass modes:

- When bypass mode is turned on, it implies that cached results are no longer used and that no new results are saved in the cache.
- When bypass mode is turned off, the cache resumes normal operation.

Syntax

```
DBMS_RESULT_CACHE.BYPASS (
   bypass_mode    IN   BOOLEAN,
   session        IN   BOOLEAN);
```

Parameters

Table 150-6 BYPASS Procedure Parameters

Parameter	Description
bypass_mode	• TRUE => Result Cache usage is bypassed • FALSE => Result Cache usage is turned on
session	• TRUE => Applies to current session • FALSE (default) => Applies to all sessions

Usage Notes

This operation is database instance specific.

Examples

This operation can be used when there is a need to hot patch PL/SQL code in a running system. If a code-patch is applied to a PL/SQL module on which a result cached function directly or transitively depends, then the cached results associated

with the result cache function are not automatically flushed (if the instance is not restarted/bounced). This must be manually achieved.

To ensure correctness during the patching process follow these steps:

1. Place the result cache in bypass mode, and flush existing result.

```
BEGIN
   DBMS_RESULT_CACHE.BYPASS(TRUE);
   DBMS_RESULT_CACHE.FLUSH;
END;
/
```

   This step must be performed on each instance if in a Oracle Real Application Clusters environment.

2. Apply the PL/SQL code patches.
3. Resume use of the result cache, by turning off the cache bypass mode.

```
BEGIN
   DBMS_RESULT_CACHE.BYPASS(FALSE);
END;
/
```

   This step must be performed on each instance if in a Oracle Real Application Clusters environment.

150.3.6 FLUSH Function & Procedure

This function and procedure attempts to remove all the objects from the Result Cache, and depending on the arguments retains or releases the memory and retains or clears the statistics.

Syntax

```
DBMS_RESULT_CACHE.FLUSH (
   retainMem  IN  BOOLEAN DEFAULT FALSE,
   retainSta  IN  BOOLEAN DEFAULT FALSE)
  RETURN BOOLEAN;

DBMS_RESULT_CACHE.FLUSH (
   retainMem  IN  BOOLEAN DEFAULT FALSE,
   retainSta  IN  BOOLEAN DEFAULT FALSE);
```

Parameters

Table 150-7 FLUSH Function & Procedure Parameters

Parameter	Description
retainMem	• TRUE => retains the free memory in the cache • FALSE (default) => releases the free memory to the system
retainSta	• TRUE => retains the existing cache statistics • FALSE (default) => clears the existing cache statistics

Return Values

TRUE if successful in removing all the objects.

150.3.7 INVALIDATE Functions & Procedures

This function and procedure invalidates all the result-set objects that dependent upon the specified dependency object.

Syntax

```
DBMS_RESULT_CACHE.INVALIDATE (
   owner        IN  VARCHAR2,
   name         IN  VARCHAR2)
 RETURN NUMBER;

DBMS_RESULT_CACHE.INVALIDATE (
   owner       IN  VARCHAR2,
   name        IN  VARCHAR2);

DBMS_RESULT_CACHE.INVALIDATE (
  object_id    IN BINARY_INTEGER)
 RETURN NUMBER;

DBMS_RESULT_CACHE.INVALIDATE (
   object_id    IN BINARY_INTEGER);
```

Parameters

Table 150-8 INVALIDATE Function & Procedure Parameters

Parameter	Description
owner	Schema name
name	Object name
object_id	Dictionary object number

Return Values

The number of objects invalidated.

150.3.8 INVALIDATE_OBJECT Functions & Procedures

This function and procedure invalidates the specified result-set object(s).

Syntax

```
DBMS_RESULT_CACHE.INVALIDATE_OBJECT (
   id          IN  BINARY_INTEGER)
 RETURN NUMBER;

DBMS_RESULT_CACHE.INVALIDATE_OBJECT (
   id          IN  BINARY_INTEGER);

DBMS_RESULT_CACHE.INVALIDATE_OBJECT (
  cache_id     IN  VARCHAR2)
 RETURN NUMBER;

DBMS_RESULT_CACHE.INVALIDATE_OBJECT (
   cache_id   IN  VARCHAR2);
```

Parameters

Table 150-9 INVALIDATE_OBJECT Function & Procedure Parameters

Parameter	Description
id	Address of the cache object in the Result Cache
cache_id	Result cache identifier of a SQL cursor or PL/SQL function.

Return Values

The number of objects invalidated.

150.3.9 MEMORY_REPORT Procedure

This procedure produces the memory usage report for the Result Cache.

Syntax

```
DBMS_RESULT_CACHE.MEMORY_REPORT (
   detailed   IN   BOOLEAN DEFAULT FALSE);
```

Parameters

Table 150-10 MEMORY_REPORT Procedure Parameters

Parameter	Description
detailed	• TRUE => produces a more detailed report • FALSE (default) => produces the standard report

Usage Notes

Invoking this procedure from SQL*Plus requires that the serveroutput be turned on.

Examples

```
SET SERVEROUTPUT ON

EXECUTE DBMS_RESULT_CACHE.MEMORY_REPORT;
```

150.3.10 OBJECT_BLACK_LIST Function

This table function returns all the object numbers currently in the blocklist.

Syntax

```
DBMS_RESULT_CACHE.OBJECT_BLACK_LIST ()
   RETURN NATURALN;
```

150.3.11 OBJECT_BLACK_LIST_ADD Procedure

This procedures adds objects to the object blacklist. These procedures only have to be run once in the cluster as they take effect everywhere at once. However, they do not persist between cluster shutdowns and startups.

Syntax

```
DBMS_RESULT_CACHE.OBJECT_BLACK_LIST_ADD (
   objNo       IN  BINARY_INTEGER);

DBMS_RESULT_CACHE.OBJECT_BLACK_LIST_ADD (
   owner       IN  VARCHAR2,
   name        IN  VARCHAR2);
```

Parameters

Table 150-11 OBJECT_BLACK_LIST_ADD Procedure Parameters

Parameter	Description
objNo	The object number.
owner	The owner of the object.
name	The name of the table.

150.3.12 OBJECT_BLACK_LIST_CLEAR Procedure

This procedure clears the entire blacklist.

Syntax

```
DBMS_RESULT_CACHE.OBJECT_BLACK_LIST_CLEAR ();
```

150.3.13 OBJECT_BLACK_LIST_REMOVE Procedure

This procedures removes objects from the object blacklist.

Syntax

```
DBMS_RESULT_CACHE.OBJECT_BLACK_LIST_REMOVE (
   objNo       IN  BINARY_INTEGER);

DBMS_RESULT_CACHE.OBJECT_BLACK_LIST_REMOVE (
   owner       IN  VARCHAR2,
   name        IN  VARCHAR2);
```

Parameters

Table 150-12 OBJECT_BLACK_LIST_REMOVE Procedure Parameters

Parameter	Description
objNo	The object number.
owner	The owner of the object.

Table 150-12 (Cont.) OBJECT_BLACK_LIST_REMOVE Procedure Parameters

Parameter	Description
name	The name of the table.

150.3.14 STATUS Function

This function checks the status of the Result Cache.

Syntax

```
DBMS_RESULT_CACHE.STATUS
   RETURN VARCHAR2;
```

> **Note:**
>
> For more information on the constants, see DBMS_RESULT_CACHE Constants.

151
DBMS_RESUMABLE

With the DBMS_RESUMABLE package, you can suspend large operations that run out of space or reach space limits after executing for a long time, fix the problem, and make the statement resume execution. In this way you can write applications without worrying about running into space-related errors.

This chapter contains the following topics:

- Operational Notes
- Summary of DBMS_RESUMABLE Subprograms

151.1 DBMS_RESUMABLE Operational Notes

When you suspend a statement, you should log the suspension in the alert log. You should also register a procedure to be executed when the statement is suspended. Using a view, you can monitor the progress of the statement and indicate whether the statement is currently executing or suspended.

Suspending a statement automatically results in suspending the transaction. Thus all transactional resources are held during a statement suspend and resume. When the error condition disappears, the suspended statement automatically resumes execution. A resumable space allocation can be suspended and resumed multiple times during execution.

A suspension timeout interval is associated with resumable space allocations. A resumable space allocation that is suspended for the timeout interval (the default is two hours) wakes up and returns an exception to the user. A suspended statement may be forced to throw an exception using the DBMS_RESUMABLE.ABORT() procedure.

151.2 Summary of DBMS_RESUMABLE Subprograms

This table lists the DBMS_RESUMABLE subprograms and briefly describes them.

Table 151-1 ***DBMS_RESUMABLE Package Subprograms***

Subprogram	Description
ABORT Procedure	Aborts a suspended resumable space allocation
GET_SESSION_TIMEOUT Function	Returns the current timeout value of the resumable space allocations for a session with session_id
GET_TIMEOUT Function	Returns the current timeout value of resumable space allocations for the current session
SET_SESSION_TIMEOUT Procedure	Sets the timeout of resumable space allocations for a session with session_id
SET_TIMEOUT Procedure	Sets the timeout of resumable space allocations for the current session

Table 151-1 (Cont.) *DBMS_RESUMABLE Package Subprograms*

Subprogram	Description
SPACE_ERROR_INFO Function	Looks for space-related errors in the error stack, otherwise returning FALSE

151.2.1 ABORT Procedure

This procedure aborts a suspended resumable space allocation.

The parameter `session_id` is the session ID in which the statement is executed. For a parallel DML/DDL, `session_id` is any session ID that participates in the parallel DML/DDL. This operation is guaranteed to succeed. The procedure can be called either inside or outside of the `AFTER SUSPEND` trigger.

Syntax

```
DBMS_RESUMABLE.ABORT (
   session_id  IN NUMBER);
```

Parameters

Table 151-2 ABORT Procedure Parameters

Parameter	Description
`session_id`	The session identifier of the resumable space allocation.

Usage Notes

To call an `ABORT` procedure, you must be the owner of the session with `session_id`, have `ALTER SYSTEM` privileges, or be a DBA.

151.2.2 GET_SESSION_TIMEOUT Function

This function returns the current timeout value of resumable space allocations for a session with `session_id`.

Syntax

```
DBMS_RESUMABLE.GET_SESSION_TIMEOUT (
   session_id  IN NUMBER)
RETURN NUMBER;
```

Parameters

Table 151-3 GET_SESSION_TIMEOUT Function Parameters

Parameter	Description
`session_id`	The session identifier of the resumable space allocation.

Return Values

Table 151-4 GET_SESSION_TIMEOUT Function Return Values

Return Value	Description
NUMBER	The current timeout value of resumable space allocations for a session with session_id. The timeout is returned in seconds.

Usage Notes

If session_id does not exist, the GET_SESSION_TIMEOUT function returns -1.

151.2.3 GET_TIMEOUT Function

This function returns the current timeout value of resumable space allocations for the current session.

Syntax

```
DBMS_RESUMABLE.GET_TIMEOUT
 RETURN NUMBER;
```

Return Values

Table 151-5 GET_TIMEOUT Function Return Values

Return Value	Description
NUMBER	The current timeout value of resumable space allocations for the current session. The returned value is in seconds.

Usage Notes

If the current session is not resumable enabled, the GET_TIMEOUT function returns -1.

151.2.4 SET_SESSION_TIMEOUT Procedure

This procedure sets the timeout of resumable space allocations for a session with session_id.

The new timeout setting applies to the session immediately. If session_id does not exist, no operation occurs.

Syntax

```
DBMS_RESUMABLE.SET_SESSION_TIMEOUT (
   session_id  IN NUMBER,
   timeout     IN NUMBER);
```

Parameters

Table 151-6 SET_SESSION_TIMEOUT Procedure Parameters

Parameter	Description
session_id	The session identifier of the resumable space allocation.
timeout	The timeout of the resumable space allocation.

151.2.5 SET_TIMEOUT Procedure

This procedure sets the timeout of resumable space allocations for the current session. The new timeout setting applies to the session immediately.

Syntax

```
DBMS_RESUMABLE.SET_TIMEOUT (
   timeout  IN NUMBER);
```

Parameters

Table 151-7 SET_TIMEOUT Procedure Parameters

Parameter	Description
timeout	The timeout of the resumable space allocation.

151.2.6 SPACE_ERROR_INFO Function

This function looks for space-related errors in the error stack.

If it cannot find a space related error, it will return FALSE. Otherwise, TRUE is returned and information about the particular object that causes the space error is returned.

Syntax

```
DBMS_RESUMABLE.SPACE_ERROR_INFO
   error_type        OUT VARCHAR2,
   object_type       OUT VARCHAR2,
   object_owner      OUT VARCHAR2,
   table_space_name  OUT VARCHAR2,
   object_name       OUT VARCHAR2,
   sub_object_name   OUT VARCHAR2)
RETURN BOOLEAN;
```

Parameters

Table 151-8 SPACE_ERROR_INFO Function Parameters

Parameter	Description
`error_type`	The space error type. It will be one of the following: • `NO MORE SPACE` • `MAX EXTENTS REACHED` • `SPACE QUOTA EXCEEDED`
`object_type`	The object type. It will be one of the following: • TABLE • INDEX • CLUSTER • TABLE SPACE • ROLLBACK SEGMENT • UNDO SEGMENT • LOB SEGMENT • TEMP SEGMENT • INDEX PARTITION • TABLE PARTITION • LOB PARTITION • TABLE SUBPARTITION • INDEX SUBPARTITION • LOB SUBPARTITION The type can also be `NULL` if it does not apply.
`object_owner`	The owner of the object. `NULL` if it cannot be determined.
`table_space_name`	The table space where the object resides. `NULL` if it cannot be determined.
`object_name`	The name of rollback segment, temp segment, table, index, or cluster.
`sub_object_name`	The partition name or sub-partition name of `LOB, TABLE,` or `INDEX.` `NULL` if it cannot be determined.

152
DBMS_RLS

The DBMS_RLS package contains the fine-grained access control administrative interface, which is used to implement Virtual Private Database (VPD).

DBMS_RLS is available with the Enterprise Edition only.

> **See Also:**
>
> *Oracle Database Security Guide*for usage information about DBMS_RLS

This chapter contains the following topics:

- Overview
- Security Model
- Constants
- Operational Notes
- Rules and Limits
- Summary of DBMS_RLS Subprograms

152.1 DBMS_RLS Overview

The functionality to support fine-grained access control is based on dynamic predicates, where security rules are not embedded in views, but are acquired at the statement parse time, when the base table or view is referenced in a DML statement.

A dynamic predicate for a table, view, or synonym is generated by a PL/SQL function, which is associated with a security policy through a PL/SQL interface. For example:

```
DBMS_RLS.ADD_POLICY (
   'hr', 'employees', 'emp_policy', 'hr', 'emp_sec', 'select', 'user_ctx', 'time');
```

Whenever the EMPLOYEES table, under the HR schema, is referenced in a query or subquery (SELECT), the server calls the EMP_SEC function (under the HR schema). This function returns a predicate specific to the current schema for the EMP_POLICY policy. The policy function may generate the predicates based on the session environment variables available during the function call. These variables usually appear in the form of application contexts. The policy can specify any combination of security-relevant columns and of these statement types: INDEX, SELECT, INSERT, UPDATE, or DELETE.

The server then produces a transient view with the text:

```
SELECT * FROM hr.employees WHERE P1
```

Here, P1 (for example, where SAL > 10000, or even a subquery) is the predicate returned from the EMP_SEC function. The server treats the EMPLOYEES table as a view and does the view

expansion just like the ordinary view, except that the view text is taken from the transient view instead of the data dictionary.

If the predicate contains subqueries, then the owner (definer) of the policy function is used to resolve objects within the subqueries and checks security for those objects. In other words, users who have access privilege to the policy-protected objects do not need to know anything about the policy. They do not need to be granted object privileges for any underlying security policy. Furthermore, the users do not require `EXECUTE` privilege on the policy function, because the server makes the call with the function definer's right.

> **Note:**
>
